To illustrate Sir Andrew Clark's Lecture on "The Question of Fibroid Phthisis,  
Bacillary and Non-Bacillary."

## Lectures

ON

## CASES OF FIBROID PHTHISIS.

*Delivered at the London Hospital,*BY SIR ANDREW CLARK, BART., M.D., F.R.S.,  
PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS.*Reported for THE LANCET: revised and rearranged  
by the Lecturer.*

(WITH COLOURED ILLUSTRATION.)

## LECTURE I.

GENTLEMEN,—Drs. Hadley and Chaplin have brought here for our consideration to-day a curious case of pulmonary disease. The patient is twenty-seven years of age and is now suffering from cough, expectoration and shortness of breath. He says he has been ill as long as he remembers; that though never seriously ill, he is sometimes worse, sometimes better; but that during the last year he has been worse than ever before. Nevertheless, he does not look ill; but for his cough he does not feel ill; he is not losing flesh; has no elevation of temperature and no other constitutional disturbance.

*Examination of the chest.*—On inspecting the chest you will see that the heart is beating in its normal place, that the right side of the chest is somewhat contracted and moves less freely than on the right, that the veins of the neck do not entirely empty when the patient inspires, and that the left side is rather lifted than expanded when he takes a deep breath. Confining our examination for the present to the left lung, there is almost everywhere increased vocal fremitus and dullness of percussion. On one spot below the angle of the scapula the dullness is accompanied by a somewhat hollow resonance, which suggests, but does not prove, the existence of a dilated tube or cavity. The auscultation one hears in the apex of the lung, hollow, bronchial breathing, coarse, moist crepitation of a slightly metallic character and increased vocal resonance, but no distinct bronchophony. From the cavicle to the base similar vocal sounds are to be heard, varying a little in intensity, from place to place. In the back of the lung we find in the supra-spinous fossa diminished tactile and vocal resonance, dullness to percussion, bronchial breathing and coarse, moist crepitation. About the lower angle of the scapula, where I before noticed a sort of tubular dullness, there is loud bronchophony of a metallic character. From this point to the base there are to be found slightly increased vocal fremitus, decreasing dullness and coarse, moist crepitation or crackling. A careful examination of the right lung elicits no physical sign of disease of sufficient importance to be dwelt upon.

*Examination of other physiological systems.*—Here, then, plainly enough is some chronic chest trouble and before endeavouring to interpret it let me call your attention to the manner in which the other physiological systems of the organism are behaving in its presence. The cardiac impulse is felt in its normal place, the area of dullness, especially on the right side, is a little increased, but the cardiac action is regular and the cardiac sounds are distinctly heard and unaccompanied by any murmurs. The arteries are soft and moderately full; pulse is about 80; the peripheral circulation, however, is somewhat feeble, for the extremities are cold and the fingers are purple and a little swollen. The digestive system is acting healthily; the urine is low in density but free from albumen; no evidence of disorder or disease in the nervous system is discoverable. Recurring to the patient's symptoms, it is particularly to be noted that the expectoration is difficult and the cough by which it is brought up is often paroxysmal and sometimes ends in vomiting. Finally, let me remind you of the patient's asseveration that "but for his chest trouble" he would be quite well.

*Summary of the facts.*—Substantially we have now elicited all the facts which are necessary for the framing of the diagnosis of the patient's malady. Certainly he has got an extensive consolidation of the left lung; certainly also he has got a cavity or dilated bronchial tube in the organ at the part corresponding to the inferior angle of the scapula. What is the nature of this affection? Consider how long it has existed and how little are its constitutional defects. There

No. 3592.

is no wasting or sweating, no fever or hurry of circulation, no loss of strength or grave disturbance of digestion. Consider furthermore that whilst almost the whole of the left lung is consolidated, the right lung remains substantially unaffected. Plainly this affection is not a common one and I doubt if any acquaintance, however close, with your text-books would enable you to determine its exact nature.

*The nature of this affection.*—Is the consolidation malignant? Is it tubercular, or is it, as I believe, fibroid? When we remember that the patient is young, that his malady has lasted for years, that it is confined to one lung, the normal limits of which it has not exceeded, that it has produced no progressive loss of strength or colour and that there is no fever; furthermore, when we consider the patient's allegation that but for his cough he would be well, we shall find in this constitution sufficient justification for discarding the idea of malignant disease being the cause of his symptoms. Is the consolidation tubercular? In these days this is a somewhat difficult question to answer, but I think I shall be within the limits of an accepted generalisation if I say that a consolidation with the occasional presence in it of tubercle bacilli is tubercular, and that one in which no tubercle bacilli are ever found is not so. There are, indeed, some enthusiastic pathologists who will declare that every chronic consolidation of this sort, not malignant, is, even without bacilli, tubercular. But here the enthusiasm of a theory has undermined the judgment of facts and I will not follow them so far. Now the sputa of this patient have been examined over and over again and at various times of the day, but no tubercle bacilli have been found, though the searchers have been experienced experts. According, therefore, to the modern theory of tuberculosis as generally received, this consolidation of which we are speaking is not tubercular. Furthermore, I may draw from the older methods of pathological reasoning, happily not yet extinct, an additional argument against the tubercular nature of this consolidation. I have examined over more than 4000 bodies, and I have never yet found one lung wholly invaded by what would have been accepted as tubercular lesions without evidence of the existence of tubercle, either in the other lung or elsewhere. Well, then, if this consolidation is not malignant and not tubercular, what is it? Doubt on the point is no longer possible. It is fibroid disease of the lung. We thus conclude that the cause of the patient's malady resides in the fibroid consolidation of the lung accompanied with what I shall for the moment assume to be a cavity therein.

*Definition of phthisis.*—Nosologically this corresponds to our generic definition of phthisis, for phthisis, as I have always taught you, is that assemblage and progression of symptoms due to the ulcerative or suppurative destruction of more or less circumscribed non-malignant deposits in the lung. I shall not contend that this definition is perfect, but I do contend that in the present state of our knowledge it is the best that you can produce, for it has the fewest drawbacks and the greatest advantages of any other definition of which I have read or heard. Observe that this definition is a generic one, for it assumes that there are different consolidations and that therefore there are varieties of phthisis; and if the critical study of these alleged varieties of phthisis proves that they are different in their origin, in their progress, in their relations to the organism, in their duration, in their response to treatment and in their issues it is important—nay, it is necessary to the advancement of the practical side of our art that such varieties should be described and named.

*Acute tuberculosis.*—Observe, in the next place, that this definition of mine excludes tuberculosis, for acute tuberculosis differs in many respects from phthisis and especially in this respect: that it is invariably an acute disease. It comes on somewhat suddenly, often in the midst of apparent health, like an ordinary fever; it runs a febrile course; it deposits throughout the organism small miliary bodies called tubercles, which in the lungs almost never give rise to cavities and at the end of six weeks or two months it puts an end to life. Now, this is not a history of phthisis, and for reasons which I will not now stop to state it has been of set purpose excluded from my definition. When I am told that the anatomical structure of the tubercle of acute tuberculosis differs in no material particular from the anatomical structure of the tubercle of chronic phthisis, I will reply that the anatomical structure of a morbid product can never be made the true criterion of the disease which produces it. For the true criterion of the nature of a disease lies in its life history and not in the anatomical forms whereby it finds but a

A

partial expression which may be shared by other and different diseases.

*The modern theory of tuberculosis.*—Here it will be necessary for me to make a short digression in order that I may bring before you in greater detail the modern theory of tuberculosis. This theory is based upon the brilliant researches of Dr. Robert Koch. He discovered in all tubercular and scrofulous consolidations the microphyte, the tubercle bacillus. He discovered that this bacillus could be grown and multiplied outside the body; that by the inoculation of animals with the descendants of pure cultures of this microphyte tuberculosis could be produced and that from the acute tuberculosis thus engendered other animals could be similarly affected. He went still further and he showed that in phthisis these tubercle bacilli were always present; that they were capable through inoculation of producing tuberculosis in animals and that the tuberculosis so produced could be propagated downwards for several successive generations. Here I must ask you to observe that the disease produced by the inoculation of tubercle bacilli is acute tuberculosis and that there is no conclusive evidence to show that the disease which I have defined as phthisis is ever so produced. I do not deny that there is any close organic alliance between acute tuberculosis and phthisis, but I do earnestly contend that there is such a fundamental organic difference between the conditions of which they are respectively the expressions, that the advancement of our art requires that this difference should not be overlooked. Now this brilliant discovery of Robert Koch and the theory based thereon make it plain that there are two factors in the evolution of tuberculosis—the tubercle bacillus and the soil on which they grow. For it is certain that the tubercle bacilli will not flourish in every soil and that the soil which at one time has favoured their propagation will at another time cease to do so.

*Tuberculin.*—I presume you are all familiar with the immense efforts that have been made during the last two years for the discovery of some agent which would destroy tubercle bacilli and so bring about the cure of phthisis. You doubtless all know how much attention has been devoted to the bacilli and how little to the soil in which they grow and doubtless you know also how unhappily these efforts have ended. At present it cannot be pretended that either Koch's tuberculin or any other similar agent which has been tried for the destruction of the tubercle bacilli has produced a single authentic cure of phthisis. To my mind the reason is obvious and conclusive; for the more I study the phenomena of phthisis the less becomes my expectation that any agent will be discovered by which the tubercle bacilli will be killed and the progress of phthisis stayed.

*Reaction of the organism to irritants.*—Why do I say so? Here I will bring you to the consideration of one of the most important facts in connexion with all such cases as this. Phthisis, as I have defined it, does not consist in any specific action of the bacillus or of the products of its living action. It consists in the reaction and in the nature and character of the reaction of the tissues of the organism to the irritations which the bacilli and their products create. Now organisms are different and they often respond very differently to the same irritations and thus it happens that these tubercle bacilli give rise to products of irritation and therefore forms of phthisis which are different from each other, which have their origin in different states of constitution, which have a different assemblage and progression of symptoms, which respond differently to their environments, which pursue a different course and which issue in different structural results.

*The soil.*—Every bacillus implanted in the lung produces by its irritations at least two different forms of structural products, the fibroid or the pneumonic. If the fibroid dominates, the course of the resulting disease is slow and cold. If the pneumonic dominates, the course of the resulting disease is usually rapid and always febrile. And if the pneumonic product dominates and if its elements are composed of rapidly growing and rapidly decaying epithelial-like cells, and if the masses produced by their agglomeration assume a caseous character, there is developed a form of disease known as galloping consumption, which has an individuality of its own sufficient to distinguish it from every other form of phthisis. Now, if all these things are so, would it not be infinitely better for us to spend less of our time in what seem vain attempts to destroy these microphytes and more of our time in studying the character of the soil in which they will or

will not grow? For all my experience points to the conclusion that it is mainly, if not entirely, through the influences which we may become able to exert upon the soil that we may best hope to control or to stay the progress of phthisis.

*Scientific retrogression.*—Now as the structural products of tubercular bacillary irritation in the lung vary in form and structure and as each variety has a different life-history from the other and as these life-histories are most diverse, I regard it as a most scientific retrogression to slump them together and obscure their organic distinctions in one name; for if it be just to say—and I contend that it is—that these varieties of phthisis differ in their origin, in their course, in their complication, in their response to their environments, in their duration and in their issues, then surely it is not merely just but necessary to the progress of our art that they should be separately recognised and separately named.

*Non-bacillary phthisis.*—I have one thing more to say. It has been alleged by Koch—and it is generally believed in London—that every case of phthisis, as I have defined it, is microbial, is associated with and dependent upon the presence and the action of tubercle bacilli. For my own part I presume to deny the allegation and to contend that whilst the great majority of cases of phthisis are bacillary there is a considerable minority of cases which are non-bacillary, in which at no period of their history can bacilli be found. To this denial it is sometimes replied that if the bacilli were not there when you sought for them they were there when you did not, or if they were very enthusiastic and proportionately polite they will say that you were unable to find them and that they were certainly there. Some years ago I had in my own wards three cases of what I designated as non-bacillary fibroid phthisis. I invited two or three of my more distinguished contemporaries to examine these cases and to demonstrate the existence of the tubercle bacillus in them. They failed and, justifying their failure, said, "These are quite exceptional cases and do not break down our generalisation"; but, gentlemen, it is just the exceptional cases of this kind that demand the most careful consideration, for although they do not bear immediately or greatly upon our practical clinical teaching, they bear sufficiently upon it to justify me in calling your attention to it at this time.

*Cavity or dilated bronchus?*—Now let us return to our patient. To what condition are we to ascribe the physical signs here near the lower angle of the scapula—to a dilated bronchus or to a cavity in the lung? The physical signs of themselves will not enable us conclusively to distinguish between them and yet it is of supreme importance that the distinction should be made, for if we are dealing with a cavity the future of the patient will probably be one thing; if with a dilated bronchus, probably quite another. A careful microscopic examination of the sputa will enable us conclusively to solve the problem. If we find in the sputa several connected areolæ of elastic tissue we shall be enabled to say without hesitation that there is a cavity in the lung, and not only that but, according to the conditions of the areolæ, we may be able to say whether the cavity is old or new, stationary or rapidly progressive; but if instead of connected areolæ of elastic tissue we find leashes, threads, or bands of elastic tissue we shall not be justified in stating that the cavity exists in the lung, for such forms of elastic tissues may come, and do often come, from the bronchial walls. Now, this patient has areolæ of elastic tissue in his sputa, wherefore he has a cavity—he has a cavity in a fibroid consolidation and his malady is fibroid phthisis.

*The diagnosis.*—But we have still another question to determine concerning the patient before our diagnosis is complete. Is this phthisis bacillary or non-bacillary? Both Dr. Hedley and Dr. Chaplin have examined the sputa on many occasions with the utmost care and have never been able to discover the presence of tubercle bacilli.

*Not a question of terms.*—I have been labouring hard to bring you up to this particularity of diagnosis—this bacillary fibroid phthisis. Is the labour in vain? Have I been wasting your time to carry you to no other issue than a mere distinction of names, or does not this particularity of diagnosis carry you to a distinction of things of which it is of the utmost importance for you to know. This is my belief; for again I earnestly contend that without recognising the fundamental verity of these distinctions you will fail to recognise the varying characters of the soil in which the bacilli grow, the different nature of the structural changes which they effect, and therefore the chief factors concerned

in the evolution of phtysical lesions of the lung. The diagnosis which I have made determines, in some measure at least, the prognosis. For if the diagnosis had been bacillary tubercular phtisis, then the duration of the patient's life must have been limited to a very few years. But the diagnosis being fibroid and non-bacillary, the patient, barring accidents, may achieve the fullest term of years allotted to man.

*Importance of the prognosis.*—I know of no capability in a doctor which contributes more to usefulness in his art and success in practising it than the capability of forming an accurate prognosis; and of no capability more difficult to acquire. For the prognosis does not determine merely the direction of the patient's future life, but it determines in many and important ways the lives of households and of families. It cannot be otherwise than of supreme importance to all persons connected with a sick man to know, with some approach to certainty, whether he is likely to live for two years or for thirty; and a careful study of the natural history of the varieties of pulmonary phtisis will enable you with comparative ease to form a correct prognosis of individual cases of each variety.

*Illustrative cases.*—Dr. Hadley will remember how some years ago, to illustrate this subject of prognosis in the varieties of pulmonary phtisis, I brought before the class of clinical medicine two young girls about eighteen years of age, each suffering from a different variety of phtysical disease. The first was tall, pale, florid, thin, with finely cut features, dark eyes, languid manners, and an expression of serious illness. Her chief complaint was weakness and a recurrent sense of almost insupportable exhaustion. She had a short cough, with scanty mucoid expectoration in which tubercle bacilli were found; she became breathless on exertion; her heart was small and beating over 110 times a minute, her evening temperature reaching 102°; she had morning sweats and the physical signs of tubercular disease were confined to some moist crepitations in the summits of both lungs. The second girl was short, fair, coarse-featured, fat and healthy-looking. Her only complaints were cough and mucopurulent expectoration and breathlessness on exertion; her appetite and digestion were good; she had no fever; and she was not only full of activity, but able for work. She had extensive consolidation and contraction of the left lung; the heart, which was large and otherwise healthy, lay in the middle of the left axillary region; the pulse was about 70 and the breathing about 20 per minute. There were no signs of disease in the right lung. I pointed out that the first girl had few physical signs of pulmonary disease, but profound constitutional disturbance; and that the other, with signs of extensive pulmonary disease, had no obvious constitutional disturbance of any kind. I further pointed out that whilst the former case was one of advancing tubercular disease, which would probably terminate within a year, the latter was one of fibroid disease, not incompatible with the longest duration of life. The tubercular girl soon afterwards was seized with diphtheria and died and the autopsy revealed the presence of grey tubercles in the summits of both lungs. A few months ago I learned that the second girl was alive and well. Only yesterday I saw, with Dr. Ford Anderson of Belsize-park, a gentleman, seventy-nine years of age, in whom I discovered a contracted fibroid lung and a displaced heart. He had no pulmonary symptoms at the time and was seen for a malady of another sort, but on cross-examining him I elicited the fact that for fifty-five years he had something remarkable in his left lung, of the nature of which no one could give him any satisfactory account. Just one other illustration of the duration of one of these varieties of pulmonary phtisis and I shall have done. Some years ago I was called into consultation with Mr. Burton to see a gentleman over eighty years of age, who was suffering from pulmonary phtisis and reported to be very ill. He was an Irishman and full of Irish humour. It was not difficult to see that he was striving to make himself appear worse than he really was. He was suffering from a recent bronchial catarrh, grafting upon a long-standing lesion of the right lung. He was able to take food; he had no elevation of temperature and no hurry of circulation. The urine contained a small quantity of albumen with no casts. The right side of the chest was greatly contracted and the impulse of the heart was felt beating above the right nipple. Nothing was found in the left lung beyond mucous râles and on its posterior base some

moist crepitation. He declared himself to be very ill and expressed a doubt if he could live out the day. I bantered him a little and then he asked me how long I thought he had been ill. I replied, "Perhaps fifty years." "You are quite wrong, doctor," replied he, his face beginning to brighten with humour, "I have been ill sixty years and here is the proof of it." Whereupon, he took from under his pillow a document signed by Sir Philip Crampton and Dr. Graves certifying that the patient was labouring under phtisis and not likely to live.

*Factors in prognosis.*—Returning again to the case under consideration, we have to settle the question of prognosis. What is the course which it will probably pursue? What are the possible perils into which the patient may fall? How long will the disease last before it puts an end to life? The answers to these questions demand close and varied consideration of the moral as well as of the physical characteristics of the patient. In the first place, the patient's malady is not hereditary and so far as my knowledge extends fibroid phtisis is never so. In the second place, the disease does not exhibit the marks of a diathetic affection. It is confined to one lung; incidental acute affections possess their common characteristics and run their usual course; the disease has continued for years without impairment of the general health and at this moment the patient is free from constitutional disturbance. Furthermore, the patient is a man of regular and temperate habits, he seems to be "right-minded" and he leads an occupied and a tranquil life. All these considerations contribute to justify a favourable prognosis and to warrant us in saying to the patient and his friends that, barring accidents and assuming that he will continue to walk in the ways of physiological righteousness, he may live for many years and die at last from some other affection. But in giving such a favourable prognosis you must clearly accompany it with the necessary qualifications. It is never pleasant and it is sometimes humiliating for one patient whose duration of life you have estimated at a quarter of a century to die within two years and for another patient whose life you have estimated at the lesser value to live for years and pester you with annual apologies for being alive. This patient is liable to many complications which may either permanently damage the general health or even put an end to life. Among the acute complications I will mention bronchitis, pleurisy, pneumonia and nephritis. Contrary to theoretical expectation, these acute complications are usually well borne, pursue a favourable course and seldom leave serious mischief behind. Of the chronic complications to which our patient is exposed I may specify cardiac hypertrophy, gastro-hepatic catarrh, diarrhoea and albuminous urine. Again, whilst it is certain that some cases of fibroid phtisis never become in the modern sense tubercular, it is equally certain that others do—that, in different words, the living soil becomes so altered in its characters that the tubercular bacilli become capable of growing and multiplying therein. Furthermore, hæmoptysis is not an unfrequent complication of fibroid phtisis both in the bacillary and in the non-bacillary varieties. Lastly, let me warn you that the favourable prognosis which I have given of our patient could not be given of any other patient who, in all other conditions equally favourable, had tubercular bacilli in his sputa. In any circumstances whatever the prognosis of fibroid phtisis is more favourable than the prognosis of tubercular phtisis; but the presence in the fibroid lung of bacilli—which may grow, multiply and emigrate to all parts of the body—adds an element of great gravity to the prognosis of a case otherwise in all respects favourable.

In my next lecture I purpose bringing before you a series of cases of fibroid phtisis that you may be enabled to compare one with another and become familiar with the varying aspects which they assume. To Drs. Hadley and Chaplin, who have been for some time engaged in a critical study of the varieties of phtisis, I owe the privilege of bringing these cases to your notice; and, indeed, but for their able and indefatigable help these clinical demonstrations of fibroid phtisis could not at present have been made.

[We would direct attention to the coloured lithograph which accompanies this lecture and which illustrates very clearly the essential features of the disease which forms the subject of Sir Andrew Clark's Lectures.—ED. L.]

ABSTRACT OF A

Lecture

ON

## BRUISES OF INTERNAL ORGANS.

*Delivered at St. Bartholomew's Hospital,*

BY SIR WM. S. SAVORY, BART., F.R.S.,

LATE PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND;  
CONSULTING SURGEON TO ST. BARTHOLOMEW'S HOSPITAL.

GENTLEMEN,—We are familiar enough with bruises of superficial parts, but perhaps less attention than they deserve has been given to bruises of internal organs, for contusions of viscera, although noticed in our works on surgery, receive but little attention in practice and are perhaps commonly recognised only in their severer forms. Yet it is obvious that bruises of important internal organs must as a rule be in their nature and clinical history far more mischievous than the bruises which are so frequently seen in and immediately under the skin. One reason of the comparative neglect of their study is no doubt to be found in the fact that so little attention is usually called to their existence after death. If observed at all, they are passed by with slight notice in the search for injury of a graver nature. Illustrations of simple contusions are very rarely to be met with in our museums—hardly ever, except in conjunction with, and as a part of, some more serious lesion. The absence of such illustrations, which is, I think, to be regretted, is due, in part at least, to the fact that the characteristic appearance is difficult to preserve. Of course much depends on the colour, which rapidly fades on exposure to light. There is in our museum a portion of the left ventricle of the heart of a child, which at present shows very plainly and beautifully two or three small bruises of the muscle. First let us glance at the nature and clinical history of bruises and then let us shortly review, in the way only of illustration, without any attempt at a full study, bruises of some of the more important internal organs. Bruises of course, like almost all injuries, vary widely in degree. In its usual form bruising means rupture of portions of tissue, including that of the minuter vessels. Hence hæmorrhage and extravasation to which the characteristic stain is due. But one can imagine bruises so slight as to involve little or no rupture; while, when the injury is so severe as to produce visible laceration of texture, the simple bruising of parts becomes merged into the effects of the graver lesion. It would be generally said that you cannot have bruising without laceration—that, in fact, laceration is an essential part of bruising. Although this may be conceded from a pathological point of view, yet clinically it is of some importance that the distinction should be drawn. In simple bruising there is not necessarily laceration visible to the naked eye—no distinct gap or rent of the injured substance,—the rupture of vessels is made apparent only by the ecchymosis. The amount of blood extravasated in bruises of course varies widely, and depends not only on the nature and extent of the actual injury, but on the vascularity and delicacy of the structure which has sustained it. This hæmorrhage, when copious, often masks the other effects of bruising. Just as when the substance of tissue is largely torn we refer to the rent or laceration and not to the bruise, so when there is copious hæmorrhage either in the form of a distinct collection of blood in the injured part, which is called "hæmatoma," or when it escapes into adjacent cavities, we speak and think of this rather than of the injury on which it depends.

I propose now to consider cases of what may be called "simple bruising," in which, although there are necessarily laceration of tissue and extravasation of blood, neither the rent nor the hæmorrhage constitutes a prominent feature of the injury, but in which, nevertheless, the damage done is, I venture to think, worthy of more attention than is usually given to it.

Bruises of the brain are, I believe, far more common than is usually supposed and worthy of much more attention than they have hitherto received. In works on surgery contusion of the brain obtains a passing notice and occasionally, as at St. George's Hospital, a specimen to show contusion of the brain is to be found in our museums; but in practice it is for

the most part included in the more vague and comprehensive condition of concussion. The relation of contusion to concussion of the brain presents some points of great interest. On what happens in a case of concussion pure and simple we are not perhaps quite clear; certainly, we are not agreed, whether it be due to some sudden and temporary change in the minute vessels in the way of spasm, or whether—which I venture to think is more probable—it is due to some more subtle and profound molecular disturbance of the brain substance itself. As a matter of fact we know that cases of simple concussion severe enough to prove fatal are so very seldom seen that some even doubt whether they ever actually occur. That, however, concussion of itself pure and simple may prove fatal, and that more frequently, when death from injury to the brain is attributed to other causes it is really due to concussion I have no doubt and the facts and arguments for this belief I have given elsewhere. So far, however, as the brain itself is concerned, the chief changes that are associated with severe concussion are contusion or bruising. In the worst instances this is accompanied by laceration of the brain substance and copious hæmorrhage, so that the blood collects into a distinct mass, but many cases occur, short of these, in which there is neither visible laceration nor blood-clots, but simply a bruised condition of the cerebral substance and this perhaps in a situation opposite to the part struck. When in such an instance a section of the brain is made, the white or grey matter, as the case may be, exhibits a patch or patches, pink or red from bloodstain; and when these are more minutely examined, especially after water has been allowed to flow freely over the surface, numerous minute points or specks of blood appear scattered over the stained area. In these places the substance of the brain shows the effects of bruising. There is here some rupture of substance and some extravasation of blood, but no visible laceration and nothing which would be called hæmorrhage. There cannot, I think, be any reasonable doubt that this condition frequently occurs as the result of injury to the head short of any graver effect and that such cases usually terminate in recovery. Under the head of concussion of the brain, cases are described in which recovery is not rapid and direct, but more prolonged and circuitous, in which the patient passes days and even weeks in a state of partial unconsciousness or constant drowsiness, with sometimes fits of restlessness, from which perhaps he may be temporarily aroused to make short replies to simple questions, but into which he immediately relapses when left to himself. Then, as consciousness is gradually restored, the mind remains in a dull and lethargic state, interference of any kind is often resented and the temper is sometimes strangely altered for the worse. Usually headache more or less severe is complained of. But the bodily functions in general in this stage are performed fairly well and there is no fever or sign of serious disturbance in any other organ than the brain. In such cases many months often elapse before complete recovery is assured and during this period its progress is easily interrupted by any attempts to exert the mind. Patients in this state complain that they cannot attend to business, that they are incapable of sustained mental effort, that they have lost the power of self-control, that their senses of sight, hearing, and taste are strangely disordered and so on. Many such cases, in more recent times, have acquired interest of another kind from the fact that they have been the result of accidents on railways.

Now I am not asserting that such a state as this, even in its more severe forms, may not be the result of what I have called simple concussion, that if the brain could be dissected any abnormal condition would be always visible, but seeing how different the effect of injury and the progress of the case are from that of many cases of what may be called simple concussion even in its severe forms seeing this, and coupling it with the fact that bruises of the brain are not uncommonly seen when looked for after death from other causes, I think, to say the least, it is reasonable to assume that in such cases as I have alluded to we have to deal with the effects of contusion beyond those of concussion pure and simple. To be sure, the treatment of such cases does not turn upon the precise view which is taken of their nature, whether they are regarded, as perhaps they generally are, as cases of mere concussion with unusually slow and irregular recovery; or whether, as it seems to me, they should be regarded as cases of concussion complicated with contusion, from which the patient continues to suffer after the effects of concussion have subsided; on either view the management is practically the same. It is on either view the insistence upon absolute and prolonged rest with careful nursing—upon

absolute rest, not of the mind only, but of the senses of sight and hearing and prolonged not only during the whole period of cerebral disturbance or defect, but for at least some time after. The danger of further mischief in these cases is perhaps not so great in the earlier stages, when the necessity of abstinence from all mental effort is obvious enough, as in the later ones when the patient, feeling himself while quiet and at rest to be tolerably well, cannot be persuaded to abstain from such activity as may be productive of mischief. Over and over again one sees patients who in spite of all precaution attempt to enter into active life, break down and are compelled to desist by headache, loss of sleep and of appetite, disorder of the senses and strange and startling sensations in various parts of the body. It is well if such strong hints are taken in time, for even the loss of this is in the end made much greater by such premature attempts.

What has been said of bruises of the brain may be applied also in general terms to contusion of the spinal cord. In examinations after death similar appearances to those found in the brain are sometimes seen in the cord—blood-stained patches in the substance of which minute extravasations may be discerned. As with the brain, the effect of such injuries during life is for the most part included in the symptoms of concussions and little or nothing is said or thought about the bruises which the substance of the cord may have sustained.

In modern times such cases are most commonly met with as the result of railway accidents, and have been no doubt described and discussed as cases of concussion. With reference to these important cases in their relation to similar injury of the brain there are two points especially which deserve attention. The symptoms of these injuries, at least the more immediate ones, are less marked in the cord than in the brain. At first there is certainly less pain and usually less local disturbance. There is sometimes tenderness over the particular region of the cord, but this is probably due to injury of the surrounding structures rather than to that of the cord itself, and there is nothing corresponding to the headache, which is often so severe in corresponding injury of the brain. As a consequence such injury is more likely to be overlooked or disregarded in the cord than in the brain, and the needful rest neglected with much greater risk of subsequent mischief. Again, even when the necessity of absolute rest after such an injury is insisted on, it cannot be carried out so fully and completely as in the corresponding cases of many portions of the brain. The functions of the cord cannot, from its nature and endowments, be placed in such complete abeyance as those of the greater portion of the brain. The activity of the vital functions is not so closely connected with what are called the highest nerve centres as they are with those beneath them. As Dr. Marshall Hall long ago put it, the true spinal system never sleeps; and sleep is never more emphatically "nature's sweet restorer" than in such cases as those now under consideration. So that while bruises of the cord are not perhaps, as a rule, more severe than bruises of the brain, there is from these two causes the impossibility of obtaining such complete rest for the cord as for much of the brain, and the neglect of enforcing in the first instance such rest as may be practicable—a far greater risk of more remote mischief of a serious kind after injury of the cord than of the brain. No doubt the wisest practice in all these cases of injury, either of the cord or brain, even when in its early effects it may appear to be trivial and the patient is disposed to disregard it altogether, is to insist on immediate and unconditional rest, and as time goes on to relax this only very gradually under careful watching when no symptoms of any further disturbance appear.

How is it that so little attention has been paid to bruises of the lung, or rather, how is it that they have been so commonly overlooked? That they not unfrequently occur is, I think, beyond dispute, and yet specimens of the injury are not shown in our museums, nor is it often recognised during life. The injury is caused, of course, by blows on the chest, and is usually associated with fracture of the ribs, especially when due to direct violence, but it may and does occur under certain conditions when the ribs are not fractured. Indeed, such injury may happen, and even laceration, without any visible injury of the chest wall, as, for instance, from the passage of a wheel over it. If at the time of the accident the glottis is closed, the lung is suddenly compressed by the external force against the retained air.

I believe the effects of contusion of the lung are usually confounded with pneumonia. In the severer cases some days after an injury to the chest wall the patient complains of more deep-seated distress; the respiration perhaps becomes

quickened; there is hacking cough, and soon rust-coloured sputa are expectorated. Then there are dulness, crepitation and other signs of consolidated lung with fluid in the smaller tubes over a limited area. These symptoms are not, I think, usually associated with much dyspnoea or fever and other signs of constitutional disturbance of pneumonia, although I should not insist on this distinction as a marked one. What is more significant during the progress of the case is that the expectoration frequently contains little pellets, or even larger clots of dark blood, which have evidently formed in the smaller tubes as the result of the injury and in time become detached. After this repair and convalescence are usually rapid and uninterrupted. It is perhaps hardly needful to remark that bruising of the lung is not necessarily accompanied by emphysema or pneumothorax or even by hæmoptysis; but in some of these cases, as in those of wound or puncture of the lung from broken rib, there is, at the time of the accident, the expectoration of blood-stained frothy mucus; but this does not last, and some days usually elapse before further evidence of damaged lung is revealed. No doubt for the first day or so the signs of injury of the lung are masked by the more impressive effects of broken ribs and perhaps of injured pleura.

These cases for the most part do well, and in subjects otherwise healthy perhaps there is not much to apprehend. It is trite to say that they require care and should never be neglected; in some instances of unsound constitution or of damaged organs the patient is not altogether free from the risk of septic infection. The liver and kidneys are no doubt often bruised, and blood then readily escapes from the vessels of these vascular organs. Examination after death frequently reveals laceration of them, and specimens showing this form of injury may be seen in our museums. This of course almost invariably includes bruising; but cases of simple bruising without distinct laceration unquestionably occur. In the case of the liver during life the diagnosis can only be guessed at, and perhaps it is a wise precaution in doubtful cases to assume its existence. In the case of the kidney the pain is, I fancy, as a rule more distinct and obvious than in that of the liver, and here there is often in addition the significant symptom of blood in the urine. The spleen, too, sometimes suffers in this way, and even the pancreas. A remarkable instance of severe bruising of the pancreas I saw some years ago as the unfortunate result of compression of the abdominal aorta by a tourniquet for the cure of aneurysm of the vessel lower down. After death the large aneurysm was found almost completely filled with quite recent clot, and the pancreas, where it lay across the spine, was terribly bruised. It may be added that during the few hours that the patient survived the operation there were no particular symptoms that could be directly referred to the damaged pancreas.

Every surgeon is familiar with the difficulty of exact diagnosis in injuries of the abdomen. Severe blows in that region, or more frequently perhaps the passage of the wheel of some vehicle over it, produce profound shock. The patient remains for some time in a state of more or less intense collapse and the degree and duration of this state is an important element in the diagnosis of any local lesion. In some of these cases the subsequent rapid progress of the patient towards recovery indicates the absence of any considerable local lesion and then the immediate effect of marked depression on the receipt of the injury we attribute to shock. In other cases the condition of collapse continues and death rapidly supervenes. In these cases we expect to find some distinct lesion of some important viscus—rupture or complete division of the intestine, for example. Everyone knows that even complete division of the whole tube of intestine may be the result of the passage of a wheel across the abdominal wall without any wound or opening in it. There is a third class of cases of great interest and importance which terminate neither in death nor in rapid recovery. The state of collapse very gradually passes off, but the patient remains pale and depressed. The abdominal wall becomes rigid and remains so and there is considerable tenderness, either somewhat localised or more generally diffused. The patient lies quietly on his back with the knees raised, and the respiratory action of the diaphragm is limited. The urine is usually passed without any material difficulty, but the bowels do not act. For the rest, the tongue is perhaps rather coated, but the temperature is not much raised, if raised at all, and the pulse is not quickened. This state will last for several days, or even for a week or two, and end in recovery. Now in these cases there has probably been bruising of important

## An Address

ON

## TOOTH CULTURE.

*Delivered at the Annual Meeting of the Eastern Counties  
Branch of the British Dental Association at  
Cambridge on June 22nd, 1892.*

By SIR JAMES CRICHTON-BROWNE, M.D. &c.,  
LORD CHANCELLOR'S VISITOR.

structures. In some of them, perhaps, such mischief may be limited to the abdominal wall, and no doubt in many instances the symptoms and effects may be explained by such injury of the abdominal muscles. In other cases I think we must believe that some portion of the intestinal canal or other structure has been contused and is suffering from the effect. As a matter of fact, we sometimes see this condition when death is caused by other graver injury associated with it and the occasional supervention of peritonitis confirms this view. The strongest evidence in its favour is furnished by the untoward result of mismanagement. If the patient be not kept at absolute rest for some considerable time, but is allowed to move too soon or too freely; still more, if he be not fed with the greatest care, to the rigid exclusion of all food likely to encourage or compel peristaltic action; and worst of all, perhaps, if the routine purge "to clear out the bowels" be administered, the supervention of inflammation in the disastrous form of peritonitis tells its own tale. Hence the importance in these cases of the most careful nursing and management. In none is there greater need for the observance of unqualified rest, of "rest in its physiological sense," as Hilton put it. And it is hardly necessary to add that the drug of chief value in these cases is opium; not merely, if need be, to relieve pain and procure sleep, but to reduce as far as practicable the natural action of the intestinal canal. In such cases, for some days at least after the injury—as for some days after an operation for strangulated hernia—we should look upon an action of the bowels as a misfortune, and when at length it may seem prudent to permit it it should be gently solicited by the use of some very simple enema, as for instance, by the injection of a few ounces of warm olive oil. Again, it must be obvious that in all cases in which the extent of injury is at all doubtful, it is wisest to keep on the safe side and to adhere to the line of treatment dictated from the graver point of view.

A word further. It is important to remember that the liability to become bruised from the same degree of injury varies very widely in different persons. While the vessels of some will resist considerable violence, those of others give way under a slight touch and soon show the discolouration of a bruise; and this, of course, is significant of the state of the structures generally. When the vessels of superficial parts are thus very easily ruptured it indicates a fragility or an unsoundness which in other regions may lead to disastrous consequences. In such cases there are usually other signs of undue degeneration. Persons advanced in life, perhaps perhaps women more frequently than men and above all those with a preponderance of fat are usually the subjects of this condition. Bruising in these instances has the same significance, and for a similar reason, as epistaxis. When due to an adequate cause, or even to a strictly local condition, it has no grave import; but the case is very different when in advanced life it is provoked by trivial disturbance. Here is a striking case in point. A fat elderly woman was brought to the hospital on account of some, not severe, accident to one of her legs. I saw her in the admission room and there was no bruise or any sign of injury on her face. She was carried into one of the wards and when in half an hour I saw her there I found her with two very bad "black eyes." Upon seeking an explanation of this I learnt that her face had not been struck in any way, but that while being carried up a step or two into the ward she had received a sudden jerk and this was the only cause to which the ecchymosis could be assigned. This led of course to a further careful examination of her state and signs of a fatty heart and other symptoms of degeneration were soon revealed. In the course of two or three days she suddenly died. It is familiar knowledge to those who "train" and to many others that as the man gets into "condition" the flesh becomes firmer and with this the liability to become bruised is very materially diminished. The importance of bearing this state of the tissues in mind in diagnosis and prognosis is obvious enough.

**MEDICO-PSYCHOLOGICAL ASSOCIATION.**—The next examination in England for the certificate in Psychological Medicine will be held at Bethlem Hospital, London, on July 7th, at eleven o'clock in the morning. The examination for the Gaskell Prize will take place on the following day at the same hour and place. Candidates are requested to give notice at once to the honorary general secretary, Dr. Fletcher Beach, Darenth Asylum, Dartford.

GENTLEMEN,—It is with unaffected diffidence and in compliance with the pressing solicitations of a valued if somewhat exacting friend that I occupy the chair this afternoon and presume to preside over a meeting of a body of men at whose feet I should sit for edification in the subjects that are to be considered here. But whatever I may lack in knowledge of the topics which are to engage your attention, I am not behind you in lively interest in them, for since I read the paper of Mr. J. Smith Turner on the Condition of the Teeth of School Children, communicated to the Hygienic Congress in London, I have realised the importance of the inquiry which he described and have sought further information bearing on it. Some special investigations which I have myself undertaken from time to time into our present educational systems in their physiological aspects have prepared me for the disclosures which you are making and I needly scarcely say that I fully accept the conclusions arrived at in your first collective report and am in complete sympathy with you in the recommendations offered in that report and during the discussions of your Association which have taken place upon it. That report is, it seems to me, a very grave and significant document, revealing a state of matters for which even those most familiar with dental defects were scarcely prepared, for it is surely startling to find that amongst 5249 children under twelve years of age, there were only 485 with normal or perfect dentures—that is to say, made up of sound teeth requiring neither filling nor extraction, that only 26 per cent. of infants at five years of age have teeth free from caries and that every 1000 children at twelve years of age have amongst them 2543 teeth affected by caries. Almost as startling as the report itself are some of the statements of independent observers by which it is supported, such as that of Dr. John Livey, who, after examining the teeth of 4000 children attending schools in Bolton, said that during the course of this inquiry he could not help observing that caries is extremely common and that indeed it is quite the exception to find a perfect set of teeth, more especially in children over ten years of age; such as that of the dental officer to the Police Orphanage at Twickenham, who said that not more than one child in three enters the Orphanage with sound teeth; such as that of Mr. Fisher of Dundee, who said that amongst 400 boys on the training ship *Mars* in the Firth of Tay, drawn from a part of the country where bone and muscle are of the best description, boys who are kept clean, well housed, clothed and dieted, he found only 80 sound sets of teeth; or such as that of Dr. Cunningham, that in a school at Hull there were 595 defective teeth for each 100 children. The fact that 10,000,000 of artificial teeth are used in this country annually, although, of course, only a small proportion of the population can procure these articles of luxury, brings home to us the truth that dental mortality is heavy in these days and that the gaps in dental circles that require filling must be big and numerous.

Putting aside for the present the important information you have supplied regarding other dental abnormalities and diseases found in school children, supernumerary teeth, honeycombed teeth, syphilitic teeth, fractured teeth, enamel defects and fistulae, I wish to confine what I have to say this afternoon to caries, the most ruinous of dental maladies, not only in childhood, but at every epoch of life; and if in speaking of it I should utter what are to you truisms or travel over ground with which you have long been familiar, I must crave your kind indulgence, which I am sure you will extend to me when you remember that my acquaintance with the literature of your specialty is necessarily limited. Even the crudities and impertinencies of an outsider, however are not without instruction to the expert and from

my stumbling steps you may perchance gather some hints to expedite your own advance.

Now, as regards dental caries, it can be scarcely necessary that I should rehearse to you the evidence that has been adduced to prove that it is now far more prevalent in this country than it has ever hitherto been and that its ravages are more widespread and serious, in the present than in any former generation, about the dental history of which we have records. You will probably agree with me that that evidence is conclusive and, indeed, I take it that your own observations on the condition of the teeth of school children make it certain that dental degeneration has now attained an ascendancy that it did not in former times possess. It is impossible to believe that the British Empire would have become what it is to-day if amongst those hardy Norsemen who pushed up their keels upon the shore at Ebbsfleet and entered upon the making of England there had been only one sound set of teeth in every ten, or if amongst our ancestors, who have extended our dominions by land and sea and won for us our civil and religious liberties by struggles in which personal vigour and endurance counted for more than they do in the highly scientific and explosive warfare of modern times, there had been all but universal rottenness of the teeth before adolescence. Depend upon it that in the England of the past the teeth were not as frail or troublesome as they are to-day. The skulls dug up on the battle-fields of England grimly and silently attest the fact and the very existence of your profession in its present magnitude in the country bears witness to it. I am not going to argue that sound teeth are the passports to power, or that biting and grinding capacity have determined the course of history, but this I will maintain, that no nation has ever climbed to pre-eminence on carious teeth, or can retain pre-eminence when its teeth are no more and that it behoves a conquering people jealously to look to its teeth and to keep them, not less than its weapons, bright and sharp. If I might alter Goldsmith slightly I would declare

"Ill fares the land, to hastening ills a prey,  
Where gums accumulate and teeth decay."

It is not an edentulous race that will finally possess the world.

When we inquire into the cause of the greatly increased prevalence of dental caries in modern times we at once perceive that it is an instance of these imperfect adjustments which we often see in living beings in their passage from a natural to an artificial and from an artificial to a more artificial condition of existence. All advance in organic evolution involves danger and sacrifice and in highly complicated organisms an advance in one direction often means retrogression in another, in which the power of adaptation is tardy or where compensatory measures have not been adopted. The resources of civilisation are more ample, nimble, and varied than those of dentition and so it has come about that the teeth have not been modified in accordance with the altered habits of life of modern times, and especially of the nineteenth century, and have not yet been adequately protected by specially devised safeguards. But in examining into the causes of the increase of dental decay which we see around us, we can go beyond a mere general statement of this kind and indicate, I believe, some of the specific conditions of modern life which are mainly responsible for it; and some of these specific conditions, as they present themselves to my mind, I venture, with great deference, to submit to your consideration.

In the first place, then, it seems to me that the greater prevalence of dental caries in these days is probably in some measure dependent on the softness and pulpiness of the food on which we for the most part feed. Hardness and toughness of food—and the food of savage and semi-civilised races is generally hard and tough—involve vigorous mastication and vigorous mastication involves a vigorous use of the teeth in their proper function and a copious flow of saliva and a copious flow of saliva involves cleansing of the teeth and gums, to which the active movements of the lips, tongue, and cheeks during mastication largely contribute. But softness and pulpiness of food—and the food of all civilised races tends to become more and more soft and pulpy—means comparatively little mastication and use of the teeth and little mastication means a diminished flow of saliva, for the far-fetched condiments of refined cookery do not stimulate the salivary glands to anything like the same extent that ordinary sapid substances with energetic masticatory movements do, and a diminished flow of saliva means diminished cleansing of the teeth,

which are at the same time imperfectly scrubbed by the feeble movement of the parts engaged in mastication, and so it comes about that when the food is soft and pulpy particles of it lodge in and about the teeth and gums; to an extent that is impossible where it is hard and tough and afford a nidus for those bacterial growths which alike by the decomposition they set up and their direct attacks are so inimical to the integrity of the teeth. It has been shown that the jaws and the muscles of mastication are larger in savage than in civilised races. I have little doubt it will be found that there is some atrophy of the parotid, submaxillary and sublingual glands in the latter as compared with the former and then it will appear that tooth-brush and dentifrice are merely auxiliaries to a natural apparatus which has to some extent dwindled by disuse.

In the second place, I would suggest to you as a specific cause of the increase of dental caries a change that has taken place in a food stuff of a particular kind and of primary importance—I mean bread, the staff of life,—from which in the progress of civilisation the coarse elements—and the coarse elements consist of the outer husks of the grains of which it is composed—have been eliminated. In as far as our own country at any rate is concerned, this is essentially an age of white bread and fine flour and it is an age therefore in which we are no longer partaking to anything like the same amount that our ancestors did of the bran or husky parts of wheat and so are deprived to a large degree of a chemical element which they contain—namely, fluorine. The late Dr. George Wilson showed that fluorine is more widely distributed in nature than was before his time supposed, but still, as he pointed out, it is but sparingly present where it does occur and the only channels by which it can apparently find its way into the animal economy are through the siliceous stems of grasses and the outer husks of grain, in which it exists in comparative abundance. Analysis has proved that the enamel of the teeth contains more fluorine, in the form of fluoride of calcium, than any other part of the body and fluorine might, indeed, be regarded as the characteristic chemical constituent of this structure, the hardest of all animal tissue and containing 95.5 per cent. of salts, against 72 per cent. in the dentine. As this is so it is clear that a supply of fluorine, while the development of the teeth is proceeding, is essential to the proper formation of the enamel and that any deficiency in this respect must result in thin and inferior enamel. If, in our dislike to grittiness, which has run parallel to our addiction to soft and succulent food and in our preference for white and fine flour, we have cut off the main source of supply of fluorine to our systems, it is not difficult to understand how we may have thereby incurred comparatively feeble and unprotected teeth, with a diminished power of resistance to adverse influences and peculiarly liable to decay. For the dense close-fitting prisms of the enamel are to the tooth what its-armor-plates are to a modern ship of war; and if they are easily penetrated, corroded, or worn away, then the fate of the dentine within is sealed. I think it well worthy of consideration whether the reintroduction into our diet, and especially into the diet of childbearing women and of children, of a supply of fluorine in some suitable natural form—and what form can be more suitable than that in which it exists in the pellicles of our grain stuffs?—might not do something to fortify the teeth of the next generation.

In the third place, I would name to you, as a cause of increased dental decay in our population, the high nervous tension of our times and the impaired nutrition which that high tension frequently entails, either hereditarily or by its operation on the individual life. It is everlastingly true that when the parents have eaten sour grapes the children's teeth are set on edge, that when the parents have been prodigal of their strength the children are impoverished in constitution. Intense vitality of the conjugating spermatozoon and ovum is necessary to give the new being a fair start on its career and to impart to it an impulse which will carry it and all its tissues steadily through the perils and vicissitudes of development and maturity to the gentle declivity of kindly old age. Such intense vitality of the spermatozoon and ovum is not to be expected when the parents who produce them are labouring under nervous exhaustion; so there are now vast numbers of human beings, the offspring of neurotic or neurasthenic parents, sent "into this breathing world," "deformed, unfinished," and "scarce half made up," whose teeth are delicate and destined to premature decay. The gastro-intestinal mucous membrano of the embryo from which the pulps and sacs of the teeth

originate may in such cases be supposed to have been wanting in formative energy, or the trophic influence from nerve centres which is exerted, if not during the papillary and follicular, certainly throughout the sacular and eruptive stages of dentition, may be presumed to have been defective. It is to be remembered that as early as the fourteenth week of embryonic life, when the membrane of the dental groove with its adherent follicles and their pulps are stripped off, there may be seen dental nerves running along under the follicles and distributing twigs to each of them; it is certain that from this time till the completion of dentition at the twentieth year the development of the teeth is more or less under nervous control. It is not to be expected, I think, that robust teeth will grow and come forth in due order in children who are kept in a state of nervous excitement or overstrain. While I am quite satisfied that inherited tendencies are more potent than personal experiences in inducing the dental debility which we encounter in nervous children, I still cannot acquit our modern system of education, with the over-pressure into which it so often runs, of some share in its causation, directly through interference with the growth and eruption of the teeth, as well as indirectly through interference with digestion and secretion and the consequent establishment in the mouth of conditions favourable to dental caries. It is, I think, corroborative of the view that nervous tension contributes to dental caries that your statistics show that as regards caries better class schools are in a worse condition than those in which lower class children are educated. Better class children have of course more care bestowed on their teeth than those of a lower class, but they are at the same time of more nervous temperament and are more subject to nervous strain. With the view of ascertaining how far dental defects and decay are associated with arrested development of the nervous system, I carefully examined, by the permission of Dr. Shuttleworth and with his kind assistance and that of Dr. Telford Smith, the teeth of 113 idiots and imbeciles in the Royal Albert Asylum at Lancaster about a fortnight ago. I cannot here of course enter upon any details or give even a general summary of the observations made, but I may tell you that there was not amongst these 113 idiots and imbeciles of an average age of seventeen years one denture perfect or approaching perfection. Dental caries was present in every case save three, and in one of these three cases six teeth had been removed and in another two, so that there was only one boy out of 113 idiots and imbeciles who did not present evidence of past or present dental caries, and in him the teeth were crowded, displaced, and pitted. In a vast majority of cases the caries might be described as galloping and had been widely and deeply destructive, so that the mouths of these blighted creatures presented a lamentable spectacle and might, without hyperbole, be addressed by the dentist called in to examine them in the language used by Romeo when breaking into the vault of the Capulets:

"Thou detestable maw, thou womb of death,  
Thus I enforce thy rotten jaws to open."

Besides caries there were many other dental defects noted in the weak-minded inmates of the Royal Albert Asylum. There were overcrowding and displacement of teeth in seventy-five cases, sometimes to such an extreme degree as to produce two distinct rows of incisors in the upper jaw, the central incisors in front and the lateral incisors behind and this overcrowding depending upon contraction of the jaws, the upper jaw being V-shaped, semi V-shaped, or saddle-shaped, and invariably associated with narrowness and arching of the palate, was three times as frequent in girls as in boys. There were notching, pitting, and honeycombing of the teeth in eighteen cases and these conditions were five times more frequent in boys than in girls, while in almost every case there was observed either natural absence of a tooth or teeth, delayed eruption of a tooth or teeth, dwarfing of teeth, or malformation of one or more teeth, while in a considerable number of cases there were hypertrophy, hyperplasia or distortion of the alveolar processes and gums. Without entering on further particulars I would say that my limited survey of the teeth of idiots and imbeciles has convinced me that much valuable information will be derived from a systematic study of the developmental irregularities of the teeth and jaws which abound amongst them—a study which has been touched on by Cartwright, Ballard, Ireland, Langdon Down and Oakley Coles, which was seriously undertaken some years ago by your colleague, Dr. Talbot of Chicago, who did not, however, push his inquiries very far, but limited them to

maxillary modifications. It is obvious, I think, that the condition of the several teeth in the weak-minded will sometimes guide to the particular point in the evolution of the nerve-centres when arrest in development took place, while the distribution of caries amongst their teeth will throw light on some obscure questions in dental pathology. It is obvious that certain types of teeth are characteristic of certain varieties of mental defect and it is possible therefore that certain less marked but still perhaps distinctive dental characters are associated with certain mental qualities in those who are not weak-minded and that dentistry might afford glimpses of insight and prescience to which palmistry has only pretended to attain. It is obvious above all that cerebral abnormalities, congenital and developmental, have associated with them dental malformations and degenerations of an exceedingly marked kind and it is probable therefore that cerebral disorders in the young when dentition is still incomplete may impair the soundness of the teeth and so as I have said the nervous high tension of the age, which is so apt to induce cerebral disorder, may be a contributory cause of the increase of dental caries in these days.

In the fourth place, I would mention as a possible cause of the increased prevalence of dental caries amongst us the growing aggregation of our population in large towns, for this aggregation entails for old and young higher nervous tension than country life, a greater liability to anæmia and a low standard of health, and also to several zymotic and constitutional diseases, which not less than general reduction of health and nervous exhaustion leave their stamp on the teeth in impaired nutrition. But more than this, the conditions of town life conduce especially to those forms of dental failure which depend on bacterial onslaughts. Wherever human population is thick on the ground, bacterial population is thick in the air, and in our crowded cities we have a crowded atmosphere contrasting unfavourably with the pure air of the country and conveying constantly into the mouths of men, women, and children volumes of parasites pathogenetic and non-pathogenetic. The mouth is indeed veritably a menagerie of tame and wild bacteria. Miller found twenty-two kinds of bacteria in the mouth, of which sixteen brought about an acid reaction when cultivated in beef extract-peptone, while four produced an alkaline solution and only two a neutral one. Six organisms are invariably found in the human mouth, almost invariably another three or four, and during epidemics or when there has been contact with persons suffering from various diseases the organisms associated with these diseases and epidemics are frequently detected in the mouth mingling with its habitual inhabitants, a fact which reminds me of the curious way in which home lore sometimes anticipates scientific discovery; for as a boy I was instructed, and I daresay many of you were so also, always to spit vigorously for some time after passing a person supposed to be afflicted by any infectious disease or any house where it was known to exist. The frequent presence of such organisms in the mouth as well as of others of a still more virulent type, such as that of sputum, septicæmia, which is harmless until there is, from some cause set up, congestion or œdema of the lung, when it immediately induces croupous pneumonia or gangrene, or that of neutro-septicæmia, or such as the streptococcus aureus and albus, seems to make it incumbent on the dentist to practise thorough antiseptic cleansing of the mouth before even trifling operations are undertaken in town at any rate, for supuration and symptoms of chronic poisoning and of pyæmia have followed even the extraction of a tooth or lancing of the gums.

Whether indigenous or of occasional and foreign intrusion, the bacteria which haunt the mouth find there conditions eminently suitable to their rapid multiplication. The mouth is indeed an incubating chamber specially prepared for bacterial cultivation. In it the proper temperature is steadily kept up and the proper degree of moisture and aeration is maintained, while proper nutriment is liberally supplied in particles of food which adhere to the teeth and gums, in the desquamating epithelium, in the sugar resulting from the transformation of starch by the action of ptyalin, and in the substance of the teeth themselves. In sections of decalcified teeth stained with fuchsin and vesuvium bacteria are often seen scattered irregularly through the dentine when it is undergoing decay or softening; and although these bacteria may be only playing a secondary part, it is to be borne in mind that it is an important part and that it has only become possible because other bacteria have taken the initiative. It is when the enamel is removed that bacterial

inroads in the dentine become practicable and the removal of the enamel is effected by lactic acid and the peptonising enzyme which other bacilli produce. Miller found in his experiments on artificial decay that as long as the enamel was on the acids had no power to injure the dentine beneath, but wherever the enamel was thin or imperfectly developed the dentine was soon softened by any acid that was present and the canaliculi were then speedily filled with bacteria, which gave rise to irregular corrosion. As a large majority of the bacteria which find their way into the mouth do produce acids, it is evident that conditions that increase the bacterial supply to the mouth must promote the destruction of enamel and the invasion of the dental tubules, so that the aggregation of our people in towns must tend to the diffusion of dental caries.

There are other conditions of modern life, such as the catholic habit of smoking tobacco and the frequent administration in the treatment of debility of drugs, like the perchloride of iron and hydrochloric acid, that are rapidly destructive of enamel, which have perhaps contributed to the reign of caries that we deplore—a reign that still extends, notwithstanding an enhanced degree of attention bestowed upon the care of the teeth, as indicated by the huge increase in the manufacture and sale of toothbrushes and tooth-pastes and powders during the last twenty years. But the principal causes of the increase of dental caries have, I believe, been summed up in what I have said to you this afternoon, and the practical question that now arises is what can be done to remove these causes or to counteract their effects, to banish from our country a blight that has invaded every household and to secure to our people the boon of sound and serviceable teeth.

I have said that the present state of matters is deplorable. I am sure you will agree with me that it is harrowing to reflect on the pain and sleeplessness and distress that are daily due to dental caries in this country. Beyond these immediate evils accruing from it there are remote consequences which are even more grievous. Decay of the teeth implies imperfect mastication, delayed digestion, impaired assimilation, and a whole train of derangements which embitter and sometimes shorten life. It implies also imperfect articulation and therefore some social disability; and further than this, I would affirm that it implies sometimes danger to mental health, for in a sensitive woman, especially if she is otherwise pretty, the knowledge that she has unsightly teeth, or an obviously artificial set, is just one of those minor but constantly recurring worries and chagrins that tend to upset the equilibrium of the nervous system. The prevention of dental decay, then, and the preservation of sound teeth, become hygienic and prophylactic measures of the first moment. The boy who can masticate has a much better prospect of success and happiness in life than he who can merely munch, and the girl who dares to show her teeth will have more joy in her womanhood than she who has to veil them behind an imperturbable upper lip.

What, then, are the hygienic and prophylactic measures which should be resorted to for the prevention of dental caries and the preservation of sound teeth? The most important, the most hopeful of all of them, are those which you are met to discuss this afternoon, and which have reference to the care of the teeth of children during the period of schooling. We cannot roll back the tide of evolutionary change, abolish the potato and other pulpy foods, cool down the fever of competition, or reverse the centripetal force that is drawing our labouring classes into towns; but we can do much, very much, to avert and counteract the injurious effects upon the teeth which are exerted by such movements towards more artificial modes of life; and, best of all, we can do this in early life. The reformation of the vicious and criminal classes can only be successfully carried out amongst the young; and dental delinquency is only to be efficiently dealt with—on the large scale, at any rate—amongst those of tender years. I would, perhaps, not be going too far in alleging that if universal, continuous, and skilful supervision and management of the teeth during their development and eruption—that is, up till twenty years of age—could be secured, there would be practically nothing to do to the teeth afterwards. Once safely brought through the perils of youth they might, in a vast majority of instances, be left to themselves afterwards without any fear of their degenerating, even under circumstances of trial and neglect.

It is during childhood that tooth troubles originate and it seems to me that you are performing a great public duty, in a manner worthy of an unselfish profession, in calling

attention to the alarming prevalence of dental caries amongst school children and in asking that steps be taken to arrest its progress and prevent its spread. It seems to me that you have already made out an unanswerable case in favour of interference and I cannot doubt that you will soon be successful in securing it. You have shown the reality and the magnitude of the evil as it exists; you have shown the practicability of dealing with it remedially, and you are entitled to insist that easily attainable protection shall be given against an evil, distressing in itself and pernicious and far-reaching in its consequences.

In the first place, I would say it is the clear and pressing duty of Government or Parliament to provide that in all public institutions for the maintenance or education of the young, whether under public control, as in the case of training ships, reformatories, industrial and workhouse schools, or under the management of committees of subscribers, as in the case of orphanages, hospitals and homes the teeth of the children shall be periodically examined by a qualified dentist and everything that is needful done for their preservation. The governing bodies of such institutions stand *in loco parentis* and are bound to do everything that a good and prudent parent would do to guard the children under their charge against suffering and illness and to equip them thoroughly to earn their living. Of the children in such schools a large number ought to look forward to joining the public services and in order that they may do that it is essential that they should have sound teeth, for, as we know, a considerable percentage of young men desiring to enter the army and navy are rejected annually solely on account of dental disease.

As regards Board Schools, there would certainly be greater difficulty in introducing compulsory dentistry. There would, no doubt, be resistance by ignorant and stupid parents, and perhaps by a pig-headed society, to any operative procedure enforced to ensure to children the inestimable blessing of sound teeth, just as there is opposition to compulsory vaccination and other beneficent measures of a like kind; but, as far as I can see, there could be no objection to compulsory inspection of teeth and it is this, I respectfully submit to you that you ought to aim at and that, were it once fully introduced, would ultimately secure for us nearly all we want. Were statutory powers obtained, making it obligatory upon all School Boards and committees of schools receiving grants, to have the teeth of every child attending these schools examined by a qualified dentist twice a year; to forward to the parent or guardian of every child a copy of the dentist's report, indicating, wherever interference is necessary, what measures are required for the preservation of the child's teeth; and to provide at a cheap rate to parents and guardians disposed to avail themselves of it the assistance necessary to carry out these measures, then I feel satisfied that dental caries would be immediately circumscribed in its ravages and in a few generations become comparatively rare. The very existence of such a system would create a public opinion in favour of sound teeth, it would bring home to the people a sense of the value of tooth culture and lead to the widespread adoption of domestic precautions against dental caries, now too much neglected. In so doing it would have advantages beyond those merely relating to the teeth, for you may depend upon it, that the simple ceremonial observance of the morning and evening tooth-brush, regularly performed, exalts self-respect and so has a wholesome effect upon moral character.

A system of compulsory inspection of the teeth of school children and State-aided rectification of defects in them, such as I have alluded to, would of course entail a large outlay of money, for I contemplate that the dentists employed in this public service would be adequately remunerated for their labours; but the money would be well spent and would yield a splendid return in the increased comfort, contentment, health and vigour of our people. Rather than it should not be spent on so laudable and desirable an undertaking—and truly our school rates are already high—I would willingly see some curtailment of the curriculum which our Board Schools now offer. Nutrition, I have often said, comes before education. It is wasteful and even cruel to force education on half-starved children, and teeth, I would now assert, come before talents. It is preposterous to confer shreds of showy accomplishments on children who cannot chew their food; and sure I am that it would be for the ultimate welfare of the country (if so be that adequate tooth culture cannot be otherwise secured) even that the grand piano in some of our London Board Schools should give

place for a time to the dentist's chair. Admirable is the grand piano in its way; it is the high altar of popular æsthetics, but Chopin and Wagner ill accord with the groans of toothache. Horrible, no doubt, in its way is the dentist's chair, excruciating are the associations that cluster round it, but a timely resort to it robs it of its terrors and converts it into a benefactor that lifts us from purgatorial pains into paradisaical tranquillity and ease. The union of teeth is a far more momentous matter than that union of hearts of which we have heard so much lately.

Taken in its incipient stage caries is readily extirpated and stayed, and one of the most pleasing features in your profession at the present day, if I may say so, is the anxiety you manifest to save teeth in which it has already made serious inroads and to sacrifice as little as possible of natural dental structure. Marvellous is your skill, but you cannot yet supply artificial teeth with the true vital polish, and firm, nice and sentient in grip like the natural organ planted in its living alveolus, and your efforts are therefore directed to preserving that natural organ, even when badly damaged, whenever it is practicable to do so. Extraction which was at one time the opprobrium of your art, just as amputation was of surgery, is now comparatively rarely practised, except by old-fashioned or questionable practitioners—although it is still, I fear, too frequently resorted to by members of my profession when trespassing, as they are often obliged to do, on your domains. Blake, the artist, left us a grotesque and curious portrait of the ghost of a flea—a hideous figure covered with scaly skin of black and gold, with a murderer's countenance and eager tongue whisking out of its mouth and a cup in its clawed hands to hold the blood. I much wish he had bequeathed to us his conception of the ghost of a lost tooth, a spectre of ivory pallor and hollow visage, with quivering fangs for limbs, wormeaten, writhing in agony and waving aloft forceps and key; and even more do I wish that such a spectre could be set to plague every dentist or doctor who has been guilty of denticide or the unnecessary extraction of a saveable tooth. But no such ill-visions, gentlemen, will affright you, for I know how scrupulously conservative you are, how loth even to confer euthanasia on a perishing stump. In conclusion, I would beg very cordially to wish you success in your efforts to secure the protection of the teeth of the young and I would exhort you to steady perseverance in these efforts, undaunted by opposition, unruffled by ridicule and undiscouraged by failure, for your cause is a good and reasonable one and it must prevail. You are a wing, an useful and honoured wing, of the great army that is giving unceasing battle to the powers of darkness, disease and death.

## A Clinical Lecture

ON THE

### TREATMENT OF FRACTURE OF THE PATELLA,

WITH AN ACCOUNT OF A NEW METHOD.

By WILLIAM ANDERSON, F.R.C.S. ENG.,

SURGEON TO ST. THOMAS'S HOSPITAL, PROFESSOR OF ANATOMY IN THE ROYAL ACADEMY OF ARTS.

GENTLEMEN,—There are few fractures that give more trouble both to the patient and to the surgeon than those of the patella and the reasons for this are now well understood. The natural tendency to separation of the fragments by the "tonic" contraction of the quadriceps extensor, the effusion of blood into the joint cavity, the traumatic synovitis set up by the injury, and the intrusion of the torn prepatellar aponeuroses between the two fragments are so many natural obstacles to a favourable union, and they may be aided, perhaps in a material degree, by plans of treatment which intercept the blood-supply to the injured part and so tilt the fragments that a strong bond of union becomes a physical impossibility. Then, union of a more or less satisfactory kind having taken place, the prolonged immobilisation by which it has been secured is apt to leave stiffness of the joint, often for a long time after the patient is allowed to use the member; and ultimate freedom of motion is only obtained by painful and frequent manipulations. It is probable, moreover, that a detrimental element of a different kind

comes into play in a large proportion of the cases. There is reason to believe that fracture of the patella, when compared with fractures of the long bones, is relatively infrequent in young and vigorous persons, but is more prone to occur in subjects of a less favourable type; women and men over middle age or of feebler habit of body; and perhaps the lower tissue resistance in such cases is a predisposing cause of the lesion and of the imperfection of the reparative process. In the last four months there have been admitted into my wards seven persons with this injury. Of these, five were women, and not at all of a robust type, and two were elderly men who died within a few days of admission from ailments of a medical nature. This is of course an exceptionally bad list, but my impression of the cases that have been under my care during the last ten years is that the subjects were with few exceptions decidedly below the average in reparative power. To put this in some measure to the test I have, with the aid of my house surgeon, Mr. W. F. E. Milton, analysed the records of 274 cases treated since the beginning of 1880 at St. Thomas's Hospital and have taken for comparison the much larger number of fractures of the leg within the same period. From this it appears that the former accident is relatively much more frequent in women than the latter. Thus of the patellar fractures 35.5 per cent. were in women; of the leg fractures only 20.7 per cent. Again, the average age in patellar fracture is very high (39.7) and no less than 49 per cent. of the patients had passed their fortieth year, against 30 per cent. in fractures of the leg. Now it might be supposed that transverse fracture of the patella is especially favoured by a powerful development of the quadriceps extensor, since there can be little doubt that it is the violent contraction of this muscle that determines the breach of continuity in the vast majority of the cases; but the large proportion of women and of elderly men who are subject to the accident points rather to the predominant influence of a second factor, a diminished textural resistance in the bone, and such diminished resistance is likely to be associated with impaired reparative power.

The remedial measures, apart from the familiar elements of rest and position and local antiphlogistics, may be divided into operative and non-operative. The non-operative treatment was until a few years ago almost the only resource which the surgeon regarded as justifiable and consisted of a variety of bandages and appliances designed to draw the fragments together. I do not propose to speak of these in detail, but merely to point out that most of them were positively injurious, because they tended both to impede the circulation in the patellar vessels and to tilt the broken edges of the fragment forwards, and many if not all of the warning specimens in our museums were perhaps rather the products of misdirected surgical zeal than of nature's inability to do the work of repair. There is, indeed, little doubt that in cases not treated by operation, simple rest and extension of the limb, without any attempt to coerce the fragments of the broken bone into position, afford the best prospect of a sound union, and it is perhaps the exclusion of harmful interference that explains the success claimed in recent years for the innocent expedient of massage of the extensors. If, however, we take the results of all cases treated by non-operative measures—good, bad and indifferent—there is little serious reason for dissatisfaction. It is true that the patients were crippled for a much longer time than in most other fractures of the lower extremity, but very few of them had any further cause for complaint and the mortality was *nil*. Only two cases since 1880 were admitted into the hospital for the treatment of badly united bones; and it must of course be recollected that it is not in the patella alone that imperfect union occurs. These facts must be borne in mind in estimating the desirability of certain forms of operation. In operative treatment we have now a considerable variety of resources, all aiming to secure a close mechanical apposition of the fragments, either by immediate suture or by forces less directly applied. The suturing operations are of several kinds. The fragments may be exposed and wired after the manner of Lister; the bone may be drilled and sutured subcutaneously, after the method of Ceci; the suture may be passed through the ligamentum patellæ and quadriceps tendon and around the bone longitudinally, the wiring material being knotted externally, after the method of Kocher, or carried beneath the skin over the patella as recommended by Barker. The details of the different operations have been graphically described in a recent article by Mr. Barker and need not be repeated.

Amongst all these plans, that of Lister stands first in its

results. The effused blood is removed from the joint, the torn prepatellar aponeurosis is cut away and the two broken surfaces are accurately adapted. This is ideal surgery and the reward is all that would be expected—speedy union and early and complete restoration of the functional utility of the joint. In the series of cases quoted admirable results have been secured by my colleagues, Mr. Croft and Sir William MacCormac, from this measure. The methods of Kocher and Barker too have been very successful, although they have not the advantages of Lister's operation; but in all these the cavity of the joint is interfered with. Now antiseptics includes too many factors and directly or indirectly the coöperation of too many persons to render possible an absolute certainty of success; and so grave are the consequences of suppuration of the joint that were it to happen in only one out of fifty cases it is very doubtful whether all the benefits gained for the other forty-nine would compensate for it. The results of the ordinary treatment, however, are not good enough to permit us to rest content without seeking to improve upon them if we can do so without sacrifice of safety, and if an operation can be devised that will secure approximation of the fragments without implicating the articular cavity it should receive a fair consideration. Amongst the methods aiming at this result are Treves' adaptation of Malgaigne's hooks to grasp the patella itself instead of the quadriceps tendon and ligamentum patellæ; Marshall's plan of piercing the bone transversely above and below the fracture by pins which are drawn together by means of wire outside the joint; and Mr. Mayo Robson's operation, in which the pins are passed through the tendon of the rectus and ligamentum patellæ instead of through the bone. We have not at present a large experience of either of these three methods. The first certainly removes the danger attached to the original application of the hooks—that of penetrating the joint—and appears worthy of a more extended trial; the second must be somewhat difficult of safe performance when the lower fragment is small; and the third would appear to require some care to avoid the implication of the supra-patellar synovial pouch and to ensure that the fragments, the lower one particularly, shall not be tilted. Of course, none of these "subcutaneous" measures remove the obstacle to ideal union offered by the torn ends of the prepatellar aponeurosis; but there is no reason to believe that this tissue fills the interval between the fragments so completely as to intercept a satisfactory union if the apposition of the fragments be sufficiently close.

In the course of a dissection of the structures in front of the knee I was struck with the strength of the prepatellar fibres of the quadriceps and their strong fixation to the bone, and on passing a pin between the thin tendinous aponeurosis and the bone I found that a very considerable force of traction might be exerted without any yielding of the tissue—a force much greater than that required to ensure contact of the fragments in fracture. Acting upon this I took advantage of a series of five cases admitted into my wards to apply a new procedure. All the cases were kept for a week at perfect rest with the limb extended upon a back splint. The patient was then prepared for operation by a thorough cleansing of the skin over the front of the knee and the application for twelve hours of a moist perchloride of mercury pack. A strong steel pin, about four and a half inches long, with a lance-shaped extremity, was passed through the integuments down to the front of the upper fragment near its outer margin, about half an inch above the line of fracture, and was pressed onwards transversely nearly as far as the opposite border, the point being kept in contact with the bony surface till it was finally pushed through the skin. The lower fragment was similarly treated and it was found that approximation of the ends of the two needles at once obliterated the gap between the two portions of the broken bone. A cork was then fixed on the two needle points, and the heads on the opposite side of the joint were connected by means of a twisted silver wire. The whole joint was dusted with iodoform powder and covered with an antiseptic dressing and the limb was again placed upon the back splint. It was left untouched for a fortnight or three weeks, at the end of which time the dressings were removed and the pins withdrawn. I will not take up time by reading the reports of the individual cases, as it will be more easy and profitable to summarise the results. The patients were all women—one aged twenty-four, a fairly good subject; two aged thirty, of poor physique; one aged forty-five, an extremely stout woman; and one aged fifty-two, a person of very intemperate habits. In all the fracture was transverse and the accident was

attributable to a spasmodic contraction of the extensors consequent upon a stumble. In four of the cases the course was aseptic and painless throughout and when the pins were withdrawn the union was found to be linear; in the fifth, that of the alcoholic patient, suppuration occurred along the track of the pins and it was necessary to withdraw them at the end of thirteen days; but there was little or no pain and a good fibrous union was secured with an interval of about a quarter of an inch. This person returned home at her own request at the end of five weeks and it has since been impossible to trace her; but as she left her original home shortly after her discharge there is reason to believe that she was able to make a satisfactory use of the limb. The other patients have been kept under observation for three or four months after the accident. In all of these the result of treatment was maintained; in two there was undoubtedly osseous union; in the other two it was impossible to be certain whether the uniting material was or was not bone, but the vertical diameter of the patella was the same as in the sound limb. Some little stiffness in the joint was present in all the cases after the removal of the splint, but it yielded to treatment. The stout patient, whose weight must have exceeded 16 st., had the ill luck to

FIG. 1.

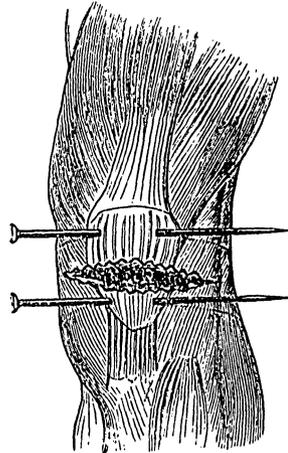

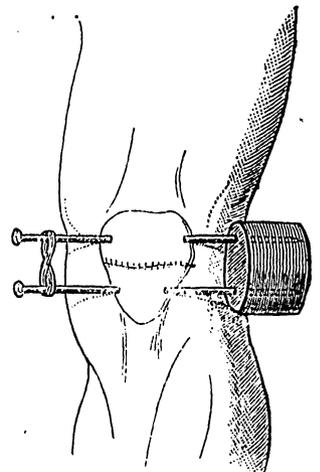

FIG. 2.

fall about fourteen weeks after the original accident and was readmitted into the hospital, with considerable pain and some swelling in the knee, but it was found that the patellar union had held good and she returned home at the end of a few days.

Taking these cases as a whole they may be regarded as very satisfactory. The occurrence of suppuration in one instance, that of the alcoholic subject—and it may here be noticed that alcoholics are singularly prone to suppuration after surgical operation, in spite of the most careful antiseptic precautions—is of interest in showing that even this accident is of no gravity and only prevents so close an approximation of fragments as in other cases where no pus is formed. The resistance to the violent strain caused by the fall in the case of the stout woman may be considered a crucial test of the strength of the union. The temporary stiffness of the joint was merely that which is observed under non-operative treatment and was not in any way connected with the use of the pins.

The patients were retained in the hospital for about six weeks, the knee in each case being kept straight in a plaster splint for a fortnight more, but this latter precaution was probably unnecessary, and in future cases I propose to shorten the period of detention and to allow earlier movement of the articulation.

Harley-street, W.

**NEW WATERWORKS, WAKEFIELD.**—The chairman of the Waterworks Committee of the Borough Corporation (Councillor J. S. Booth) performed on the 23rd ult. the ceremony of cutting the first sod of the new Withens Reservoir, on the Rishworth Moors, in connexion with the Wakefield new waterworks. The reservoir will have a capacity for 240,000,000 gallons of water. The estimated cost is £120,000.

ON POSTURE AND ITS INDICATIONS.

By T. LAUDER-BRUNTON, M.D., D.Sc. EDIN., F.R.S., &c.,  
ASSISTANT PHYSICIAN AND LECTURER ON MATERIA MEDICA AND  
THERAPEUTICS AT ST. BARTHOLOMEW'S HOSPITAL.

In a former paper<sup>1</sup> I observed that I thought medicine lost a great deal by its practitioners either not recording their experience at all, or not recording it in such a form as to be readily available for their fellow practitioners, or with sufficient precision to be really useful. As examples of vagueness and precision I instanced a verbal description of a face as commonly given, and a sketch containing all the features more or less precisely drawn. In the present paper I have tried in a very imperfect way to indicate the common postures which one meets with daily, either in patients or others, and to discover the reason why those postures are assumed. I have not attempted to draw the figures, for this would have been beyond my powers, and probably also beyond the powers of many medical men. I have simply indicated the position

FIG. 1.

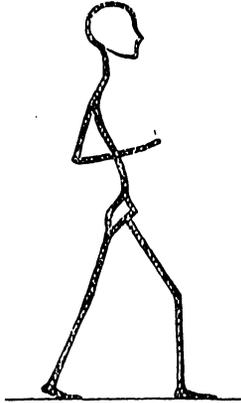

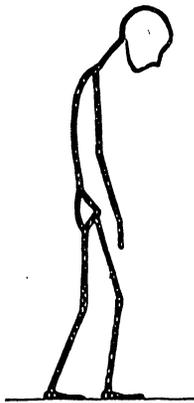

FIG. 2.

by a few simple lines such as anyone can draw. This method is one which was employed with great success by the late Professor Goodsir more than thirty years ago in illustrating his lectures on anatomy. In a few lines he conveyed the impression of the agility of the cat as compared with the heavy movements of the ox or of the elephant, and the absence of detail fixed the minds of his students all the more firmly on the main facts which he wished them to carry away. As we walk along the streets and notice the difference of attitude in the passers-by,

FIG. 3.

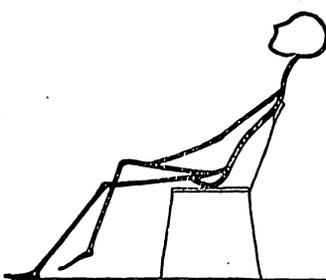

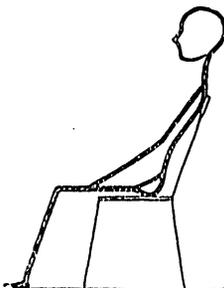

FIG. 4.

some with head erect and agile steps convey to us at once the idea of energy and activity (Fig. 1), while others with hanging heads and bended knees suggest the ideas of languor, weakness and depression (Fig. 2). It is a matter of ancient observation that such an attitude as this is associated with weak circulation, and it is probably more than three thousand years ago that the injunction was given: "Strengthen ye the weak hands and confirm

the feeble knees; say to them that are of a fearful heart, Be strong, fear not." Is. xxxv., 3, 4.<sup>2</sup> When the heart is stimulated by joy or hope the attitude again becomes erect and the gait brisk and elastic. It is by no means easy to distinguish exactly between the part played in this change by the motor cells of the nerve centres and by the circulatory apparatus, for the activity of the motor cells on which muscular action depends is itself influenced to an enormous extent by the circulation of blood through the nerve centres. We find an example of this in the

FIG. 5.

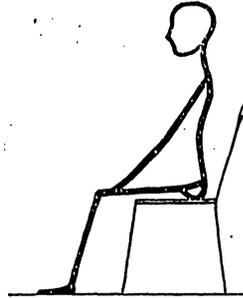

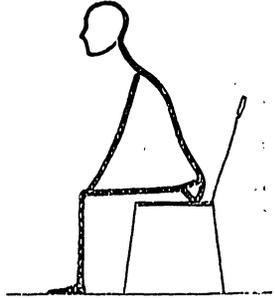

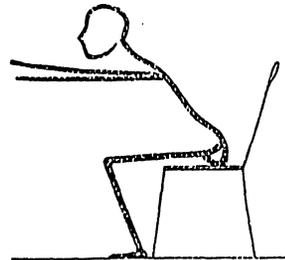

FIG. 6.

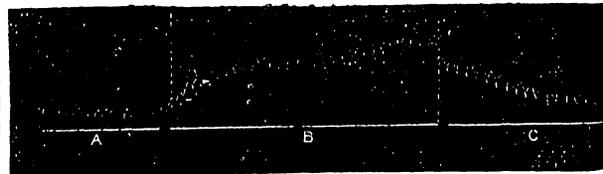

attitude unconsciously assumed by anyone engaged in conversation or argument. So long as he takes only a listless interest in the subject under discussion he may lie back in the chair with his legs crossed and his arms either hanging down or his hands laid loosely in his lap (Fig. 3). As his interest increases his attitude becomes more erect (Fig. 4), and he sits straight up, with his hands folded or laid upon his knees instead of hanging listlessly down (Fig. 5). As the interest increases still further the body is bent forwards at an angle and the hand is very probably placed firmly on the thigh (Fig. 6).

FIG. 7.

If he becomes excited in the heat of argument the body is bent forwards at a somewhat acute angle and the hand is stretched out in front and somewhat upwards as if to help the words which flow from his lips to drive the thoughts which are rapidly evolved from his brain into his opponent's mind. (Fig. 7.) In this position the flow of blood through the arterial system onwards to the brain as well as its return backwards through the veins seems to be particularly easy (Fig. 8).

FIG. 8.

Tracing from the brain. A, in upright position; B, with head inclined forwards.

This position is not only assumed during the heat of argument, whether the speaker be sitting or standing, but when one is led to assume it unconsciously it seems to give rise to a rapid and sometimes almost uncontrollable flow of ideas. Thus it occasionally becomes a cause of remorse to devout souls, who during the attempt to pray in church in this atti-

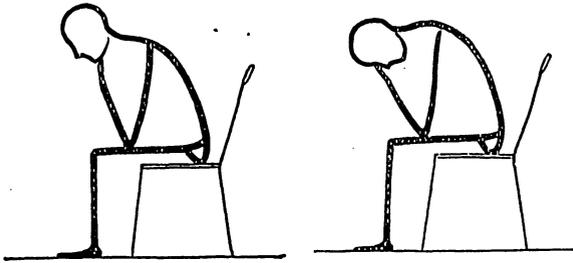

<sup>1</sup> On the Method of Zadig in Medicine, THE LANCET, Jan. 2nd, 1892.

<sup>2</sup> Also, "Lift up the hands which hang down, and the feeble knees, and make straight paths for your feet." Heb. xii., 12.

tude are sadly distracted by crowds of ideas which at once disappear on the assumption of an easy sitting posture. The circulation in the cerebral vessels and the current of ideas in the brain are very delicate things and may be modified by very slight causes; thus an attitude with the head drooping slightly more than that indicated in Fig. 6, and with the chin supported upon the hand is the one frequently assumed in deep thought, with concentration of ideas upon a single subject and no desire for immediate expression (Fig. 9). The touch of the hand upon the head seems to have a directing power over the thoughts which one would formerly have been inclined to deny, but such experiments as those of Tesla and Crookes with electric currents of very high tension give a visible illustration of phenomena previously unknown and seemingly incredible. For in these experiments a person who has put himself into the electric field renders vacuum tubes containing various substances fluorescent and fills them with a glow of coloured light by simply waving his hands over them. The tubes, which were previously dark, owe their luminosity only to the approximation of his hand, yet he himself does not feel that any special power has gone out of him. The contact of the hand with the temples seems as if it could hardly by any possibility modify the circulation in the brain or the feelings of the individual, and yet it appears to have an actually soothing effect and to be a real physical solace in cases of grief and depression (Fig. 10). At the same

FIG. 9.

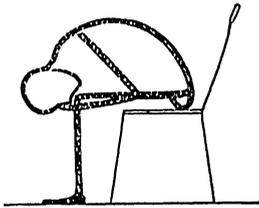

FIG. 10.

time the greater droop of the head possibly provides for a better supply of blood to the sensory parts of the brain in the posterior part of the head and thus to a certain extent counteracts the general weakness of the circulation. In the case of excitement (Fig. 7), the head being more raised, if a straight line were drawn through the axis of the body so as to represent the line of the aorta and carotid arteries, it would come out at the anterior part of the head; and blood driven onwards in this line would supply nutriment rather than the motor than to the sensory centres.

In cases where the circulation is exceedingly weak and syncope is threatened, a most useful plan is to make the patient put his head down between his knees (Fig. 11), so

FIG. 11.

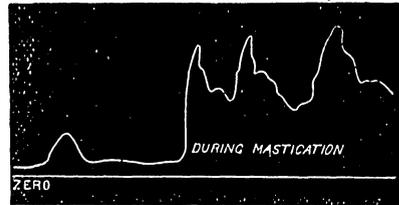

that an ample supply of blood shall reach the cerebral centres. Long ago, before the introduction of anaesthetics, a common plan of rendering patients senseless previously to the performance of an operation was to lay the patient flat upon his back and then suddenly hoist him to a standing posture by six strong men who held him by the arms, three on one side and three on the other. The brain being thus, as it were, lifted away from the blood, became so anæmic that it ceased to act before the circulation could adapt itself to the new posture.

An experience of my own once showed me how very dependent the brain is upon the supply of blood. I was called upon one night after a long day's work to write an article immediately. I sat down with pen, ink and paper

before me, but not a single idea came into my head, not a single word could I write. Lying back I soliloquised: "The brain is the same as it was yesterday and it worked then, why will it not work to-day?" Then it occurred to me that the day before I was not so tired and probably the circulation was a little brisker than to-day. I next thought of the various experiments on the connexion between cerebral circulation and mental activity and I concluded that if the blood would not come to the brain the best thing would be to bring the brain down to the blood. I laid my head flat upon the table and at once my ideas began to flow and my pen began to run across the paper. I thought "I am getting on so well I may sit up now," but the moment I raised the head my mind became an utter blank, so I put my head down again flat upon the table and finished my article in that position.

Stimulation of some branch or other of the fifth nerve seems to increase the circulation in the brain and those who are making their utmost calls upon their mental powers are accustomed to stimulate this nerve in one way or another. The late Lord Derby used to eat brandied cherries, and an experiment of Marey's (Fig. 12) proves that mastication will

FIG. 12.

Tracing of the rate of circulation in the carotid. After Marey.

accelerate the flow of blood through the carotid artery, and serves to show the wisdom of an editor whom I knew who used to eat figs while writing a leading article and even of those who indulge in the practice so disagreeable to their neighbours of chewing tobacco. Others stimulate the gustatory branches of the fifth nerve by the sweets which they suck or by the smoke of a cigar or cigarette; while a rustic called upon suddenly to answer a question will probably excite the cutaneous branches of this nerve by scratching his head, and a man of more culture may stroke his moustache or beard, press his forehead or eyes, or, like many Germans, smite his nose with the forefinger.

A similar reason may be given to explain the habit of snuffing formerly so much in vogue. The gentle titillation of the nasal mucous membrane by the snuff probably serves to stimulate the cerebral circulation and the increased arterial tension due to the efforts of sneezing so increases the cerebral nutrition that difficulties seem at once to disappear and obscurities of mental vision are so rapidly removed that snuff is said in popular language to "clear the head." The practice of snuffing has fallen to a great extent into disuse, but it may still be occasionally employed with advantage in cases of severe and persistent headache where other remedies fail to relieve. Even where such a strong irritant as snuff is not resorted to, smelling salts (sal volatile) or aromatic vinegar may give considerable relief in headache if frequently inhaled.

While stimulation of the fifth nerves just described tends to keep people awake and increase their mental activity, gentle, rhythmical stroking of the head tends, on the contrary, to make them fall asleep, and brushing the hair has this effect on many people to such an extent that the movements of the hairdresser's fingers over the scalp and rhythmical click of the shears will send some people to sleep, even at the risk of having their hair shorn to a much greater extent than would be at all pleasing to them on awakening. A gentle rubbing of the scalp, as if to loosen it upon the skull, also tends not only to sooth irritability, but to relieve and to prevent headaches.

External temperature has a powerful effect in determining posture. On a hot summer's day the natural tendency is to lie down with the head slightly raised, the arms hanging loose and one leg extended, while the other perhaps is drawn up, as in Fig. 13. The physiological reason for this posture is that in it the greatest extent of cooling is attained; for it ensures the greatest possible exposure of the largest vascular district in the body—viz., the intestinal vessels—to

the cooling influence of the external air. This is aided by the loss of heat due to the evaporation of sweat. By the slight raising of the head and the drawing up of one leg the abdominal parietes are rendered loose and the intestines tend to fall sideways and the abdomen tends to become flattened from before backwards. The greatest extent of cooling surface is thus obtained and the temperature of the body is kept as low as possible.

An entirely opposite attitude is assumed when the external air is cold (Fig. 14). The thin abdominal walls being insufficient to protect the intestinal vessels from the cooling influence of the external air, the legs are drawn up until the thick muscles of the thigh form a warm covering to the abdomen and thus prevent loss of heat from the intestinal vessels. Many people are unable to get to sleep when they are at all cold, and Rosenthal has shown that this attitude

FIG. 13.

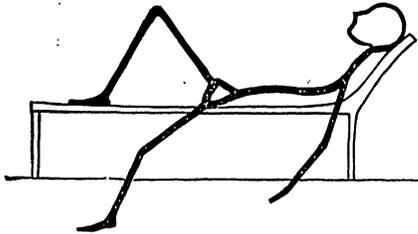

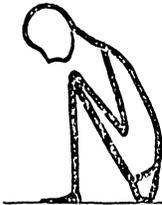

FIG. 14.

is commonly adopted by men, dogs and other animals when preparing to sleep so as not only to maintain the bodily temperature during sleep, but to allow the intestinal vessels to dilate and accommodate a mass of blood which would otherwise be driven into the cerebral circulation, stimulating it to functional activity and keeping the person or animal awake.

The attitude of the body may be altered permanently by occupation or disease in such a way that one accustomed to pay attention to this subject can frequently make out with a little trouble a good deal regarding the patient's history and illnesses. Thus a chronic cough has the effect of inflating the chest and rounding the back, so that one might almost guess from the figure (15) that the person so shaped was liable to chronic bronchitis. The more tightly a bladder is blown up with air the more tense does it become and the more does it

FIG. 15.

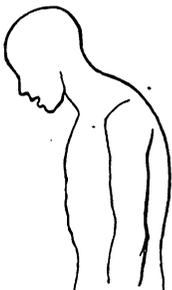

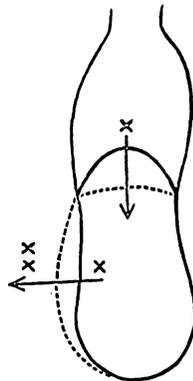

FIG. 16.

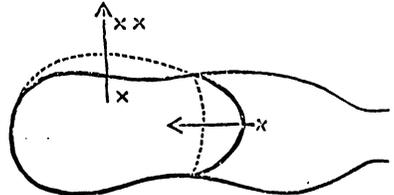

take a circular form. In the same way the more an alveolus of the lung is blown up by the efforts of coughing the more does it resemble the inflated bladder. What is true of a single alveolus is true of the chest as a whole. It tends as nearly as possible to become globular, with a circular outline not only in the transverse, but in the longitudinal direction. The sternum and vertebrae prevent it from becoming completely globular, notwithstanding all efforts, and it thus assumes the barrel shape so characteristic of emphysema, as being the nearest possible approach to a globe. In going through a hospital ward one sees here and there patients who are constantly sitting up in bed and do not lie down at all; these are for the most part people who have great difficulty of breathing. The reason for this position has no doubt been often given, but I do not recollect

coming across it in print and I cannot say whether the reason that I now give has been evolved from my own brain or whether I have learned it from others.

When a man is sitting upright the diaphragm moves up and down during respiration. (Fig. 16.) At each inspiration it descends and displaces the intestines and the abdominal walls outwards. During each expiration the diaphragm ascends and the intestines and abdominal wall return back to their former position. In the upright posture the diaphragm moves vertically, but the abdominal walls and intestines move in a horizontal plane and there is no lifting work for the diaphragm to do. The case is quite different when a man is lying on his back, for then the diaphragm moves in a horizontal plane and the abdominal walls and intestines in a vertical one. During inspiration as the diaphragm encroaches on the abdomen for the purpose of enlarging the thorax (Fig. 17)

FIG. 17.

it has actually to raise the intestines and the abdominal walls instead of merely moving them in a horizontal plane. As the diaphragm returns into the thorax during inspiration its progress will be accelerated by the weight of the descending intestines, and thus the recumbent posture may be sometimes useful in cases of bronchitis with emphysema, and so such cases may be seen sometimes lying down although there is considerable interference with the aeration of the blood. In cases of cardiac disease no benefit of this kind is obtained, and therefore we find that a large proportion of those whom we see sitting upright in bed in a hospital ward are suffering from disease of the heart.

When a patient lies upon his side the intestines also move in a horizontal plane, and this is the position usually assumed during healthy sleep, for in it there is no interference with expiration any more than when the patient is sitting upright, while at the same time the rest obtained is much more complete. The side upon which one lies is immaterial to most healthy persons and they frequently lie first upon one and then on another, turning over perhaps several times in the course of the night; but in cardiac disease or cardiac irritability without organic disease patients frequently are unable to lie upon the left side because the heart beats against the ribs with such force as to cause physical discomfort. At the same time the heart itself appears to be stimulated by the blows which it gives itself against the thoracic walls and to palpitate more violently than before. The patient is therefore obliged to lie upon the right side. A similar result may occur if the liver is enlarged or congested, for then it seems to drag upon the suspensory ligaments when the patient lies upon the left side and thus he is obliged to turn round that the liver may be supported by the ribs. If a heavy meal has been taken shortly before retiring to rest the person may be unable to lie upon his left side because the stomach drags upon its pyloric end. On the other hand, if the stomach is distended by flatulence the gases sometimes will not escape while the patient is lying on his left side and he must either be raised into the sitting posture or be turned on his left side to allow the gas to cruetate by the œsophagus and the tension in the stomach to be relieved,<sup>2</sup> for the œsophagus joins the stomach at such an angle that when the patient is on his left side the gases appear to accumulate and not to find an exit through the œsophagus, but when he is on his right side they pass upwards with comparative ease. This of course is a matter of very slight moment to patients who are able to move readily, because they adjust their own position at will and soon find out which is the most easy one for them. But when a patient is so weak that he is unable to move himself he is frequently allowed to lie flat on his back and to suffer

<sup>2</sup> I have found this practice useful. The explanation I have given of its utility was, I think, suggested to me several years ago by John Haddon, M.A., M.D.

much from abdominal distension and even from difficulty of breathing, due to the diaphragm being pushed upwards when he might be relieved by simply sitting him up for a few minutes or turning him over on his left side.

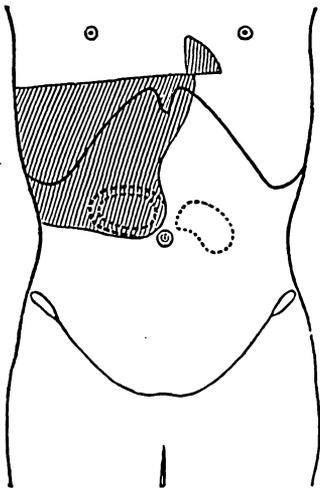

In this short paper I have made no reference to many other postures in disease, neither have I attempted to discuss the postures due to trade, nor have I attempted to make the paper complete. I have merely tried to give an illustration of an easy method of recording posture in a tolerably precise and easily understood way and have attempted to connect external signs with physiological conditions as an illustration of the method of tracking which I mentioned in a former paper in the hope of inducing others to prosecute the same line of work.

### A CASE OF INTUSSUSCEPTION ASSOCIATED WITH CANCER OF THE CÆCUM.

BY SIDNEY COUPLAND, M.D., F.R.C.P. LOND.,  
PHYSICIAN TO THE MIDDLESEX HOSPITAL.

In his monograph on Intestinal Obstruction,<sup>1</sup> Mr. Treves points out that whereas of all cases of intussusception more than 50 per cent. occur in the first decade of life, yet in the chronic varieties alone the period of greatest frequency is between the twenty-first and fortieth years. He also shows that the majority of subacute and chronic cases are of the ileo-cæcal variety—about three-fourths. These two facts may be allied with a third—namely, the association of chronic invaginations with epitheliomatous disease of the bowel. Mr. Treves<sup>2</sup> has no doubt that in some cases the new growth may arise subsequently to the intussusception, but seeing that other forms of intestinal tumour are indubitably provoking

FIG. 1.

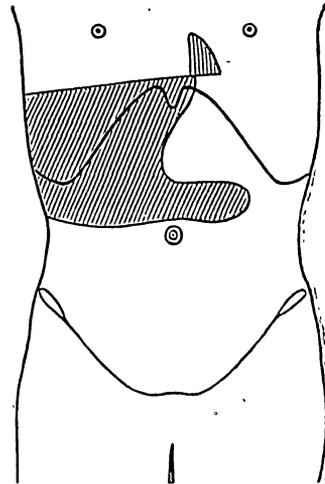

causes of an invagination, it is highly probable that in many instances the malignant growth has antedated the formation of the intussusception. In the following case we seem to have an example of this, although it is not possible to assert positively that such a sequence existed.

C. L.—, a French polisher, forty years of age, was admitted into Hertford ward of the Middlesex Hospital on Feb. 26th, 1892, complaining of a swelling in the abdomen, which had appeared after severe colicky pains, from which he had suffered for about ten days, accompanied at first with vomiting. Since childhood he had been subject to attacks of jaundice and bilious vomiting and his bowels were habitually constipated, but it was only in November last that he began to be attacked with colic. At the end of that month he began to have griping pains about the umbilical region, which came and went in paroxysms, without relation to meals or rest. He was treated at a dispensary and was completely relieved for a week, when the pains recurred and again inter-

mitted. The intervals of freedom from the colic became shorter and each returning attack more severe, until towards the end of January he was free from pain for about a fortnight. On Feb. 17th, at the close of his day's work, just after his supper, the colic recurred with great severity, "doubling him up" and causing him to vomit at times during the night and on the next day, there being very little remission of the pain until the day of his admission into the hospital, when it ceased. He was a well-developed, fairly muscular man; there was no jaundice; the tongue was moist and covered with a white fur. The abdomen was somewhat prominent in the umbilical region, and on palpation a rounded cylindrical swelling could be felt passing towards the right from the umbilicus over the lower edge of the liver in the course of the colon. This swelling was dull on percussion, the dullness being continuous with that of the liver and passing also into the right flank. (Fig. 1.) Above, the line of the hepatic dullness was at the level of the sixth rib in the nipple line. There was nothing else abnormal in the case. The lung signs were healthy, the heart sounds normal and the apex beat in the usual position. The pulse rate was not increased and the temperature was normal. The urine was acid, sp. gr. 1020, free from albumen and sugar. As there were no urgent symptoms and absolutely no pain nothing active was attempted, but rest in bed and a low diet were prescribed. Except for the fact that the tumour had apparently disappeared from the right and now lay wholly to the left of the

FIG. 2.

umbilicus (Fig. 1, area enclosed by dotted line) there was no change in his condition a week later—namely, on March 4th. The bowels, however, had not been satisfactorily opened, and under the impression that the mass was a faecal tumour (too little regard being paid to the previous history of the case) an enema of olive oil, followed by a simple enema, was administered more than once, with the result that a fairly copious motion followed each injection, containing some scybulous masses. This treatment was repeated on the succeeding two days, but no appreciable difference was observed in the size or position of the tumour. Accordingly on March 6th he was given a drachm of castor oil every four hours, which had the effect of opening the bowels freely and caused the tumour to assume a lower position. But it did not disappear, and on the 8th it seemed to be again continuous with the liver (Fig. 2), of which the dullness reached down to the umbilicus; the swelling projecting from the liver towards the left. Between this observation and the next note on the morning of the 9th the bowels had been again freely opened, whilst the tumour had entirely disappeared: the hepatic dullness was once more of normal extent, not reaching more than two inches below the costal arch and the area hitherto occupied by the swelling was quite resonant. (Fig. 3.) This change being maintained and the patient feeling quite well, he was discharged on March 12th. The idea that the case was one of faecal accumulation seemed to be borne out by the result of the measures directed to evacuate the bowel, but it is clear from the later history of the case that the condition was probably one of intussuscep-

<sup>1</sup> Intestinal Obstruction, Cassell and Co., 1881; pp. 217, 237.  
<sup>2</sup> Loc. cit., p. 200.

tion, which had become spontaneously reduced; and it seems more than likely that the attacks of colic from which he had suffered off and on for three months were also due to the peristalsis which precedes invagination and indeed causes it, or even to a series of recurrent intussusceptions.

Nothing more was heard of the patient until Thursday, May 26th, when he came to the out-patient department stating that since the 23rd he had been suffering from abdominal pain and vomiting and the passage of blood from the bowel. It appears that on the 21st he took some jalap, which opened his bowels eight times, and on the 23rd, whilst at work, he was suddenly seized with severe pain in the abdomen and vomiting. Shortly after this he passed some blood. He took to his bed and had medical advice, but the vomiting continued every four hours, as well as the mæna, and the pain did not diminish. On the night of the 26th he noticed for the first time that the motions, instead of being mere blood as hitherto, were blackish and offensive. He was readmitted on the 31st. We found him looking anxious and complaining much of abdominal pain. The abdomen, which was tender, was tense and tympanitic and was manifestly more prominent on the right half than the left. Crossing the abdomen from the right flank to the left hypochondrium there could be seen and felt a cylindrical swelling slightly curved, the concavity being downwards. It was very firm and rounded; the right half of it was dull on percussion, the dulness being continuous with that of the liver, whilst the left half was resonant. (Fig. 4.) The man was not collapsed; the

ing. It may be added that at no time during his stay in the hospital was the temperature above normal.

The post-mortem examination was made on the following day by Dr. Voelcker, from whose notes the following report is condensed. The peritoneal cavity contained a slight excess of clear fluid. The intestines were much distended and lines of red injection were observed along the contiguous coils. There was no lymph; no fecal extravasation. The hepatic flexure of the colon and the first part of the transverse colon formed a large cylindrical tumour due to the invagination into the gut of the cæcum and part of the ileum, the length of the whole mass being ten inches and a half. On laying open the colon, the mucous membrane of the intussuscepted bowel was seen to be intensely reddened and swollen and it had commenced to slough near its free extremity. Here also could be seen two orifices—namely, one leading into the appendix cæci, the other into the ileum. Moreover, at the upper part of the head of the intussusception the lining membrane was replaced over an area of the size of a crown piece by a soft, whitish, fungating and ulcerating mass of new growth. No adhesions could be made out between the serous layers of the intussusception. The rest of the intestines and the stomach showed nothing abnormal. The liver and kidneys were pale and in a condition of cloudy swelling. Both lungs were congested and œdematous, the heart was flabby, but otherwise natural. No new growth was found in any other part of the body.

The case speaks for itself. It illustrates the possibility of

FIG. 3.

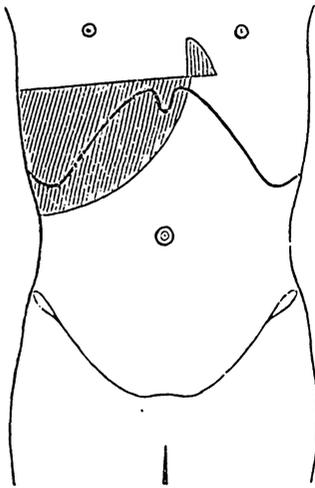

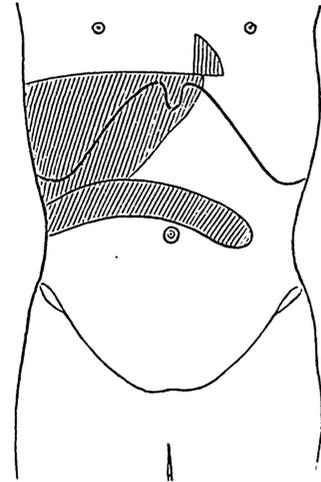

FIG. 4.

pulse was 98, fairly full and regular. There was no tenesmus. There was no doubt now that he was the subject of an intussusception, which was strangulated and probably commencing to slough. It was obvious from the duration of the symptoms, as well as the extent and probable condition of the invagination, that surgical interference was out of the question. There seemed no other alternative than to give opium freely and support his strength during the slow process which the natural cure of such a condition entails. At the same time, as the bowels had not been recently moved, the colon was gently irrigated with warm water in order to determine whether the motions showed evidence that sloughing was in progress. Some dark-brownish fluid came away having a faecal odour but containing no sloughs. The next day (June 1st) his condition had markedly changed for the worse. He had suffered from more pain in the night and had vomited about a pint of dark feculent-looking fluid, which, however, had no distinct faecal odour. The abdomen was more tense and the pain was aggravated paroxysmally. It was observed that with each recurrence of the pain the tumour (otherwise unchanged) seemed to become firmer. The man looked pinched and his pulse was smaller and harder, 120 to the minute. The symptoms rapidly increased in severity, vomiting became incessant, the bowels were opened twice, motions dark brown and fluid; no blood, mucus, or sloughs were passed. The abdomen became more and more distended, the pulse more rapid (138) and after an hour of noisy delirium he died at 6.30 p.m. During the last hour he had profuse faecal vomit-

mistaking intussusception in the adult, especially of the ileo-cæcal variety, for faecal tumour. The error has been made before, when, with a history of constipation and no urgent symptoms of obstruction, a tumour forms in the region of the colon. Fortunately, large enemata, which generally satisfactorily dispel faecal tumours, may have the same effect on the slighter forms of intussusception, with which alone the diagnostic difficulty lies; but it is remarkable that, whereas in this case enemata failed to produce that result, it took place after the administration of castor oil, a treatment which would certainly not have been adopted had the diagnosis been correctly made. On the second occasion there was no doubt at all as to the intussusception, but it is to be regretted that the patient did not seek admission into the hospital on May 23rd instead of the 31st, for then its reduction might have been successfully effected. The post-mortem examination did not show such complete strangulation, nor such advanced inflammation as was anticipated. The growth, which has the appearance of epithelioma (a microscopical examination has not yet been made), arose in the cæcum and it was probably the exciting cause of the intussusception.

Queen Anne-street, W.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—The fifty-first annual meeting of the Association will be held on Thursday, 21st prox., at The Retreat, York, in honour of the centenary of the foundation of the institution. Dr. Robert Baker will preside.

## CANCER OF THE EAR.

BY SIR WILLIAM DALBY, F.R.C.S. ENG.,  
CONSULTING AURAL SURGEON TO ST. GEORGE'S HOSPITAL.

IN the history of cancer, which is at the present time subjected to such rigid analysis and receives such able handling from the Bradshaw lecturers, it seems advisable to place on record the experiences of individuals who have more than the usual opportunities of observing the occurrence of cancer in any especial locality, so I therefore embody what experience I possess in a few observations on cancer as it has come before my notice during the past twenty years in the very limited area of the ear. With one exception, as will be noted, this area might be more limited by using the term "middle ear" and even still further by saying "the cavity of the tympanum." In the course, then, of twenty years I have only seen six cases in all, including both hospital and private practice, and, without knowing what the experience of others may have been in a similar time, I should be inclined to say that, considering the opportunities I have had, cancer of the ear is comparatively speaking a rare disease. It is to be remembered how exceedingly often the mucous membrane which lines the tympanum is left in an exposed position, this being due to the fact that an enormous number of persons pass the largest part of their lives with a perforation of the tympanic membrane in one or both ears. The first point to be observed is that in the four cases I had seen up to 1885 and in all the recorded cases I could find (and there were very few) the patients had suffered for a considerable time from a discharge from the ear, evidently arising from a perforation, before any symptoms of malignant disease appeared and that in the early stages the appearances most closely resembled polypus arising from the tympanic cavity or ordinary bone granulations. Thus the presence of a constant discharge acted as a local irritation in each case. But in the first case everything, so to speak, arose *ab initio* from a local irritation, even the perforation itself. This case may be found recorded in vol. lxii. of the Medical and Chirurgical Transactions in a paper on "Disease of the Mastoid Bone" as follows:—

"In March, 1878, A. S.—, a married woman aged thirty-two, whilst picking her left ear with a hair-pin, ruptured the tympanic membrane and soon after the accident came under my notice as an out-patient of St. George's Hospital. With the exception of this lesion she was, in all respects, in good health. The rupture did not heal and in a few days, from the fistulous opening thus established, there was a purulent discharge. A month later, after an attack of pain in the ear, which was followed by facial paralysis of that side, I again examined the ear and found a polypoid mass filling up the cavity of the tympanum, the membrane having by this time quite gone. She now came into the hospital. I removed the polypoid growth, and the pains in the ear, which had previously been considerable, passed off. Her stay in hospital on this occasion was three weeks. On July 31st, when she again applied for relief and was admitted, she stated that she had suffered from no further pain until within five weeks, when acute pain in the ear came on and soon afterwards the parts over the mastoid process became swollen and tender. Two weeks ago, she said, the skin over the swelling broke down and a little bloody matter was discharged. The ragged wound at that time observable was the result, and from this wound had been coming ever since a quantity of watery, very foul-smelling discharge. The skin over the mass was bluish, the tissues were infiltrated and the edges of the wound were everted and hard. In short, the disease was to all appearance malignant. There were no enlarged glands, neither was there any history to be obtained of cancer in her family. No loose bone could be detected, although a large surface of bone was exposed. From this time she rapidly wasted; the wound increased in size until it formed a large cavity discharging most offensive matter and she died on Nov. 12th from exhaustion without any head symptoms or hæmorrhage."

The origin of the perforation here was traumatic, but the origin of the cancer was a discharging surface. The same might be said of a case reported in the Pathological Transactions for 1850 by the late Mr. Cooper Forster, for although the boy was knocked down by a cab and so received a violent blow on the head, he is said to have after this suffered

from great pain in the ear, followed by facial palsy, so that although the blow was the cause of the inflammation within the tympanum, the suppuration in this cavity preceded the appearance of cancer. I am able only to mention two cases in which this precedence of suppuration did not obtain. One was in the last case which I saw—a woman about fifty years of age—whom I saw on Feb. 15th of this year with Dr. Meek of Herne-hill. There was no history of inflammation of the tympanum. She had constant gnawing pain in the ear for three months, a partial facial paralysis coming on very gradually and a most fetid discharge from the ear with occasional bleeding. The external canal was filled with a soft-looking, exuberant mass, which when examined by a probe had a spongy feel and bled upon the most gentle manipulation. In short, it had all the appearance of a malignant growth. A distinct family history of cancer gave strong additional probability to the diagnosis. On removing the mass under ether a few days later it was found to be soft and pulpy. On examining portions under the microscope, Dr. Rolleston, the curator of the museum at St. George's Hospital, reported: "Sections show typical cell-nests composed of squamous epithelium surrounded by granulation tissue. The growth is therefore a squamous-celled epithelioma which has probably been growing for a considerable time." This was the character in all the cases I have seen except one, when I had not the opportunity of an examination. This patient died on May 4th, having developed a week previously some symptoms of cerebral irritation but none of pressure. I learned this from Dr. E. H. Young's letter to Dr. Meek, Dr. Young having attended her at Okehampton up to her death. Like other cases which I had seen at the time of death, the growth had involved a considerable area. In one instance the internal carotid gave way and the patient died in her sleep from suffocation. Amongst the six cases the one solitary example in which the disease did not start in the tympanic cavity it commenced by an ulceration over the mastoid process close to the junction of the outer ear and proceeded inwards, eroding the mastoid.

There is not much more to be said about cancer of the ear except to repeat that in one case only was a predisposition discoverable; in one case only did the growth commence elsewhere than in the tympanic cavity; that in two cases (and this includes Mr. Cooper Forster's) an injury started the suppuration; that they all died within six months of the discovery of the growth; that the proportion of cases in which a perforation is followed by cancer is extraordinarily rare; that there is only one case of tympanic origin that was not preceded by suppuration; that considering how frequently the tympanic cavity is the seat of suppuration, this surface possesses a remarkable immunity from cancer; finally, that cancer of the ear is one of the rarest of diseases.

Savile-row, W.

## REMARKS ON THE EVACUATION OF DÉBRIS AFTER LITHOTRITY.

BY REGINALD HARRISON, F.R.C.S. ENG.

SURGEON-MAJOR FORBES KEITH having described in THE LANCET of June 11th, 1892, a method of removing stone fragments after lithotripsy other than by the process of evacuation with the aspirators at present in vogue, I will describe a procedure I have seen during the last twelve months at M. Guyon's clinic at the Necker Hospital and elsewhere in his practice, which seems to possess certain advantages. I have adopted it myself to some extent and I know that other surgeons think favourably of it. There can be no doubt that the shortcomings of lithotripsy are chiefly connected with the difficulty existing of guaranteeing that every fragment, however small, is removed and that nothing is left behind on the completion of a crushing operation which is capable of furnishing a starting point for another concretion. Of all the conditions favourable to the reproduction of stone this is probably the most fertile one and all proposals tending to diminish the liability in this direction are deserving of careful consideration.

M. Guyon's practice, as I have now observed it on several occasions in public and private work, is as follows. The patient being fully anaesthetised, the fenestrated lithotrite is introduced, and the stone is not merely broken up but absolutely pulverised. In the last case I saw, a urate-phosphate stone with

a diameter which only just brought it within the grasp of the largest lithotrite, was subjected to a process of trituration which lasted for twenty-five minutes by my watch, without, I believe—as far as I can remember—a single withdrawal of the instrument. When no fragments could be felt with the lithotrite the evacuating catheter was introduced. The latter consisted of a full-sized instrument with a large eye on either side of the beak. No aspirator was attached to it such as we are in the habit of using for withdrawing fragments by suction-pressure, but after the bladder had been allowed to empty itself spontaneously of its contents by the catheter an ordinary syringe was attached to the latter and about six ounces of warm boracic lotion were gently injected. Then the syringe was disconnected and the bladder allowed to empty itself, this process being continued until the contents of the syringe were returned absolutely pure. The bladder was finally washed out with a solution of nitrate of silver (1 per 1000) and a rubber drainage catheter was passed and retained for twenty-four hours. The operation was completed in forty minutes and considerably over an ounce of stone powder was withdrawn suspended in boracic lotion. The total amount of blood was little more than sufficient to colour the water and entirely disappeared before the syringing was completed. I examined the débris after it had all been collected. In its moist state it had the appearance and feel of soft homogeneous mud. There were no appreciable fragments of stone in it.

The following were the points noticeable in this and similar procedures, as elsewhere observed. 1. The use of the lithotrite to produce this effect was necessarily more prolonged than where mere fragmentation is the object. This, with the patient under an anæsthetic, is a matter of no importance so long as the lithotrite is carefully used. 2. The less frequent introduction of lithotrites and evacuating catheters along the urethra. This is a point of some little importance where the prostate is large and the deep urethra irregular. 3. The back action of the suction apparatus by means of which fragments of stone often become impacted in the sacculæ and lacunæ which are found in bladders complicated with enlarged and irregular prostates is done away with. The force of a syringe is probably less than that of the back action of a strong rubber bag compressed by the hand. Further, impalpable wet powder is substituted for irregular fragments of stone. The latter by their nature are not only more liable to become impacted in depressions within the bladder wall, but by their movements under the force of the aspirator to wound the mucous membrane, as illustrated particularly by Surgeon-Major Keith in the paper referred to. 4. With the syringe there is no chance of fragments once withdrawn being washed back by any return current into the bladder. No aspirator that I have yet seen is free from this objection.

I am not aware that there are at present any statistics indicating the relative frequency of recurrence after these two methods. That the subject is worthy of careful consideration is evident from the large number of recurrences which follow lithotripsy, more particularly in those cases which are further complicated with conditions rendering the patient completely dependent on the use of the catheter.

Lower Berkeley-street, W.

## ON ACTINOMYCOSIS OF THE FOOT, COMMONLY KNOWN AS MADURA FOOT.

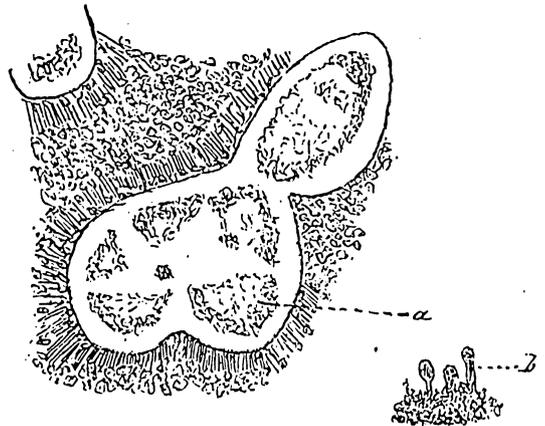

By R. T. HEWLETT, M.B.,

DEMONSTRATOR OF BACTERIOLOGY, KING'S COLLEGE, LONDON.

In 1886 Dr. Vandyke Carter<sup>1</sup> drew attention to the close resemblance between mycetoma (Madura disease) and actinomycosis, in their clinical and pathological characters and microscopic appearances. With regard to the latter, he says: "This resemblance obtains as regards both dimensions and form of the granular central body, with its ray-like envelope and exudation-cell surroundings; and incidental differences apart, it is so distinct that for my own part I cannot but infer that in these two instances at least the foreign bodies must be of an approximate character. There are no other structures I am aware of in the whole range of pathological histology which could compare so closely as these two; and in ordinary scrutinies, with like conforming

results, the inference would be as just intimated. .... I am disposed to conclude that one form of actinomycosis presents a morbid structure which is nearly homologous to that characterising a frequent variety of mycetoma." In the same year at the Pathological Society, in a discussion on a paper by Dr. T. Acland on Actinomycosis, Dr. Bristow<sup>2</sup> expressed the opinion that similar appearances were met with in actinomycosis and Madura disease.

Bassini<sup>3</sup> in 1888 examined a case of Madura foot and, though he failed to recognise the true nature of the disease, the description which he gave, as Baumgarten<sup>4</sup> pointed out, at once recalls to mind the pathology of actinomycosis. In January last Mr. Kanthack exhibited specimens of Madura disease of hand and foot at the Pathological Society. I was not at the meeting and can only judge of the nature of his communication from the short reports which appeared in THE LANCET.<sup>5</sup> Mr. Kanthack is reported to have stated that the Madura disease was undoubtedly due to a fungus and that this fungus was identical in its staining reactions with actinomyces. In May last Dr. Curnow received a specimen of Madura foot from Surgeon-Major Hatch, I.M.S., and presented it to Professor Crookshank, who asked me to examine it by the modern methods used for actinomycosis. The disease occupies the whole of the foot and the lower third of the leg. The foot is enlarged, the bones softened and carious and small abscess cavities are scattered through the tissues and communicate with the surface by several sinuses, the external openings of which have raised and thickened margins. There are other small cavities containing many fine yellowish particles, the so-called roe-like granules, and hence the specimen belongs to what has been described as the pale variety of Madura disease. The raised margin of a sinus was removed and sections prepared from it. In the unstained condition the appearances are characteristic. Scattered through the sections are yellowish bodies varying somewhat in size and frequently of a more or less reniform shape and occurring in groups of three or four or more. These bodies are somewhat granular, have distinct margins and are surrounded by an indistinct, radiating structure, beyond which again are round cells, the whole being enclosed in a distinct fibrous capsule. The appearances in stained specimens are conclusive as to the nature of the fungus. By the method of Gram the so-called "fairy-rings" of the fungus

Section from Madura foot stained by Gram's method and with orange-rubin. a, Network of fine filaments stained blue,  $\times 250$ . b, Clubs at margin stained with orange-rubin,  $\times 800$ .

are occupied by a central network of fine, branching, interlacing filaments stained blue (a), but the club-shaped bodies are unstained. By staining with orange-rubin, however, typical clubs can be demonstrated at the periphery (b).

No doubt the presence of a network of filaments and the apparent absence of the club-shaped bodies have been the causes of hesitation in fully recognising the identity of actinomycosis hominis (including Madura disease) and actinomycosis bovis. As Professor Crookshank demonstrated at the International Congress of Hygiene last summer, the actinomyces is a pleo-morphic organism; in cattle the clubs are almost

<sup>5</sup> Jan. 23rd, 1892.

<sup>1</sup> Trans. Med. and Phys. Soc. of Bombay, No. ix., 1880, p. 80 (abstract in THE LANCET, vol. i. 1880, p. 321).

invariably well marked and readily stained by Gram's method, while there is a central area which as a rule remains unstained. In man the reverse of this is the case. These two extremes, however, are connected by intermediate forms; in cattle the filamentous network, so characteristic of the disease in man, occasionally appears. In the disease in man the clubs can usually be demonstrated, in sections by special methods of staining (orange-rubin &c.), but especially by examining the fungi in the fresh state.

Mr. Kanthack is reported to have stated that actinomycosis bovis cannot be stained by Gram's method unless the saponaceous and calcareous matter be first removed. This, however, is not the case, brilliant results being obtained by Gram's method without preliminary treatment when clubs only are present and in the rarer bovine cases in which filaments and clubs are found. The microscopical appearances in Madura disease, both in the stained and unstained conditions, are then identical with those in actinomycosis; clinically and pathologically the diseases resemble each other closely and there can no longer be any hesitation in accepting the view first put forward by Dr. Carter that Madura disease is a manifestation of actinomycosis in man. Professor Crookshank concurs in this opinion and I must thank him for allowing me to publish the case and for helping me with the literature of the subject.

## Clinical Notes:

### MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

#### NOTES FROM A PRACTITIONER'S CASE-BOOK.

By H. HOWARD MURPHY, M.D. CANTAB.

*Chorea in the Adult.*—Early in March, 1892, a lady aged twenty-six had follicular tonsillitis which she had suffered from several times previously. She had never had rheumatism nor had any others of the family. After a week the temperature still kept up and the tonsils remained large, though inflammation had quite subsided. A few days later jerky movements were noticed in the right hand and arm which developed shortly into a typical attack of general chorea. The movements ceased during sleep, but were violent enough by day to make the skin red and threaten to ulcerate over the elbows and knees. The mind was much affected, memory a blank even of events occurring a few minutes previously, recognition of relatives often failing for a time; the speech was very slow and jerky, imaginary events related as real and persons falsely accused of unkind actions. There was a loud mitral systolic murmur. After six weeks there was much loss of flesh and weight and she could not stand at first. Now, three months from the commencement, she is quite well in every way and the murmur has gone. She was treated all through with salicylate of soda, a course that seemed rational to me if there is any connexion of chorea with rheumatism. I should be glad to know if this treatment has been used by others and its result. Arsenic in increasing doses was also given for a month during the period of most severe movement, followed by iron and strychnia as this abated. The writers on chorea say that complete recovery is not usual in adult patients.

*Dislocation of Patella.*—A few days ago I was hastily summoned to see an elderly woman who "had put her knee out," the messenger said. On arrival the left leg was fully extended, could not be bent and was suffering some pain. On examination the patella was obviously much displaced; its upper edge projected very much forwards, its lower edge, with the attached ligamentum patella, was correspondingly depressed, dipping into the joint, and the skin and tissues at each side of the ligament bulged forwards, partially overlapping it. There was no fracture or lateral rotation. She could not bend the knee at all and I could hardly move the patella laterally even with some force. The lower end of the patella I concluded had got caught on the transverse ligament connecting the semilunar cartilages, or perhaps on one of the cartilages themselves. It was reduced by traction and flexion of the joint, when, with a loud snap, the patella recovered its

position and the patient could freely move the joint. Immediate removal to bed and an icebag did not suffice to prevent a considerable though painless effusion following. The displacement occurred while she was kneeling on a chair with the left knee bent and reaching forwards and the right foot was on the ground. When she stood up and straightened the limb she was unable to flex it and noticed the distortion. I have not been able to find any mention of such a dislocation of the patella (if it deserves such a title) in any of the textbooks.

These cases, medical and surgical, were followed a few days ago by an obstetric one.

*Procidencia Uteri.*—A woman about twenty-seven years of age engaged me to attend her in her confinement at the end of May, 1892. She had had one child seven years before by a former marriage and had suffered ever since from a bearing down of the womb, which she alleged occasionally protruded from the vagina, but which she had always been able to replace herself. Her husband called me out of bed about a fortnight before the time she expected, saying she had her womb down and could not get it back and was suffering dreadfully. On arrival I found a mass rather larger than my fist protruding from the vagina, which grasped it pretty tightly. Its covering was a dry mucous membrane appearing like the lips. It was oedematous, moderately firm and had the tube-like os in the centre. After steady compression and cleansing and anointing with antiseptic ointment it was with some difficulty reduced, nor did it tend to come down again. Next morning labour pains had set in. On examination the swelling had entirely gone; the os was the size of a shilling, its margins thin and sharp. To my surprise a very slow and tedious labour from a rigid os resulted and was only terminated next night by forceps. The patient has done well since, but when she gets up some support to the uterus will no doubt be necessary.

East Twickenham.

#### THE EFFECT OF BLANK CARTRIDGES ON TISSUES.

By J. M. ATKINSON, M.B. LOND. &c.

T. Y.—, aged thirteen, was admitted to the hospital at 11.50 A.M. on Feb. 24th, 1892, in a state of collapse occasioned by hæmorrhage from a wound in the left groin. On examination there was a wound in the left inguinal region, circular in shape, about the size of a ten-cent piece, situated just below Poupart's ligament, one inch external to the line of the femoral artery. This was filled with blood-clot and on removing the pad and bandage with which it had been dressed there was copious hæmorrhage from the wound. This was controlled by pressure on the left external iliac artery. The patient being anaesthetised, the A. C. E. mixture being used, this wound was explored and was found to extend inwards some inch and a half, tearing up the muscles and completely severing the femoral artery. The two ends of the artery were tied with a silk ligature, the wound was syringed with corrosive solution and a small drainage-tube inserted, the edges being brought together with catgut. The collapse was extreme, the pulse improving slightly under the influence of the anaesthetic. Ten minims of ether were injected hypodermically and hot-water tins applied, the left lower limb being swathed in cotton wool. By 3 P.M. he had rallied considerably and told me that he was picking up lead at the range at Kowloon that morning and had been shot. Enemata of brandy and beef-tea were given and one-tenth grain of morphia injected hypodermically. Shortly after 7 P.M. his pulse became much weaker; some six ounces of a neutral saline solution were transfused, without any relief, however. He gradually sank and died at 7.50 P.M.

*Neurosis.*—The left femoral artery was found to be severed just below its origin, both ends being secured by ligature; the muscles in the region of the wound were torn to pieces. After careful examination no trace of any "wad" or foreign body could be found. There was no charring of the edge of the wounds. The clothing of the boy was examined and an irregular tear was found in the left leg of the trousers corresponding to the wound in the boy's thigh; there was no charring of the fabric. On February 25th and 29th experiments were made by Dr. Lowson and myself in the presence of Lieut. Hall and Fleet-Surgeon Mahon, H.M.S. *Impérieuse*, on the effect produced by firing from a Martini-Henri rifle blank cartridges similar to those served

out to the Blue-jackets on the morning this happened, at different distances on cloth &c. The boy's trousers were used and on firing at a distance of two inches there was an irregular tear produced in the cloth with no charring; at a distance of three inches the fabric was charred and at twelve inches it was fired. On placing a piece of the cloth in front of a turnip and firing at a distance of two inches a tear was produced in the cloth and a cone-shaped hole in the turnip, some two inches in depth, with traces of uncharred powder round about, very similar to the hole produced in the boy's thigh. I have no doubt that the wound was caused by the firing of a blank cartridge from a Martini-Henry rifle, the nozzle of the rifle being within two inches of the boy's body.

Government Civil Hospital, Hong Kong.

#### A PEBBLE IN THE EAR FOR EIGHT YEARS WITHOUT THE PATIENT'S KNOWLEDGE.

By W. R. H. STEWART,

AURAL SURGEON TO THE GREAT NORTHERN CENTRAL HOSPITAL, &c.

A SINGLE lady, kindly sent by my colleague, Mr. Macready, consulted me for deafness on the left side, which had lasted off and on for some years. It had become much worse the week or two before coming to me and there was a rather distressing "hammering" noise in the ear. I found the left meatus plugged with a mass of hardened wax. On using the syringe for its removal out dropped a pebble, evidently from the sea beach. In shape it might be called an irregular cube, measuring on its longest side five-sixteenths of an inch, the other sides being three-sixteenths and one-eighth. The patient had no idea the stone was in the ear and as she had not been to the seaside for over eight years it must have been in the ear all that time. The case is, I think, interesting, for it is strange that so large a pebble had remained all those years in the ear without the patient's knowledge. It also confirms the opinion that a foreign body may lodge in the meatus for a considerable time without producing mischief, provided no injudicious instrumental attempts have been made to remove it.

#### ST. THOMAS'S HOSPITAL.

CASES ILLUSTRATING THE TREATMENT OF RECURRENT PELVIC PERITONITIS BY ABDOMINAL SECTION; REMARKS.

(Under the care of Dr. CULLINGWORTH.)

WE commence this week a series of cases recently under the care of Dr. Cullingworth, in which it was necessary to perform the operation of abdominal section. The cases described had a number of points in common which render them of very great interest; in all there was a history of attacks of abdominal pain due to pelvic inflammation and its consequences and in all there was much disease, which could only be cured by the removal of the diseased structures. It is worthy of note that in nearly all of them the operation was one of considerable difficulty and it was necessary to employ drainage of the pelvis afterwards. The results of the treatment are most satisfactory.

CASE 1.—P. B—, aged twenty-five, single, a dressmaker, was admitted into the Adelaide ward on March 2nd, 1892, complaining of abdominal pain and swelling. She had enjoyed good health till three years ago, when she was laid up for three months with an attack of rheumatic fever. Two years and a half ago she was confined to bed for several days by an attack of pelvic inflammation following gonorrhœa. She has since been liable to similar but less severe attacks of pelvic pain. Menstruation has been regular and normal till the first week

in December, 1891, when her last period occurred. A fortnight later—i.e., in the third week of December last—she was suddenly seized at midday, while at work, with severe pain in the abdomen and legs. She left her work and went home to bed. The pain in the abdomen continued. A doctor was called in and discovered a swelling in the lower half of the abdomen. The patient had not been conscious of the presence of a tumour in the abdomen till it was noticed by her medical attendant. She has remained in bed ever since; poultices and leeches have been applied with little relief and hypodermic injections of morphia have been administered every night or very often in the morning, on account of the pain and restlessness. She has lost a good deal of flesh and her bowels have been very constipated.

On admission the patient, a thin, highly intelligent, anæmic woman, complained of continuous abdominal pain and swelling of eleven weeks' duration. On examination the abdomen was somewhat resistant and considerable pain and tenderness were complained of, especially in the left iliac region. A smooth tense swelling was defined occupying the left lower half of the abdomen, extending upwards as high as the umbilicus. On the right side was a smaller swelling, its upper limits reaching a point midway between the pubes and umbilicus and extending outwards as far as the outer third of Poupart's ligament. A distant sulcus could be felt between the two swellings superiorly. Both were absolutely fixed and on the left side there was indistinct fluctuation. On bi-manual examination the lateral and posterior fornices were found depressed. The cervix was high up and almost obliterated and the external os closed. Two rounded swellings could be felt through the vaginal roof separated by a distinct sulcus; the smaller one on the right was smooth, soft and rounded and apparently continuous with the cervix, any movement imparted to it by the external hand being directly appreciated by a finger placed on the cervix. The uterine sound was not passed. A hard crescentic mass was felt in Douglas's pouch.

On March 10th, eight days after admission, abdominal section was performed. There had been no material alteration in the physical signs, except that fluctuation had become more evident in the swelling in the left side. Maximum temperature since admission 99° F. On opening the abdomen two suppurating ovarian cysts were discovered; the larger one on the left side contained over a pint of greenish-yellow, inoffensive pus, which was withdrawn by trocar and cannula. The contents of the smaller cyst on the right side were of a similar character. Both cysts were intimately adherent to surrounding parts and especially to the rectum. The body of the uterus, normal in size, was pushed forwards behind the pubes. The broad ligament partially enveloped the cysts anteriorly. There was no cellulitis. The Fallopian tubes were thickened and elongated, but otherwise normal. The operation was somewhat protracted and rendered extremely difficult by reason of the number and density of the adhesions. The right cyst was ruptured during its separation from the neighbouring parts and its purulent contents escaped into the peritoneal cavity. The abdomen was freely douched with boracic-acid lotion, a glass drainage-tube inserted and the wound sutured with silkworm-gut sutures. The patient was returned to bed in a collapsed condition. Temperature 95.6°, pulse almost imperceptible at wrist; cardiac pulsations 154. She gradually rallied and convalescence was afterwards rapid. The sutures were removed on the seventh day; the indiarubber tube, which had replaced the glass tube, was discarded on the twelfth day. The patient got up on the sixteenth day and left the ward on April 22nd, the wound having been healed for ten days. She reported herself a month later in good health.

CASE 2.—E. C—, aged thirty-two, married, was admitted into the Adelaide ward on March 8th, 1892, complaining of severe pain and swelling in the lower part of the abdomen. She was married at the age of nineteen and had never been pregnant. She had menstruated regularly till six weeks ago, when her present illness began. Up to this time she had enjoyed good health. No history of gonorrhœa. Six weeks ago the patient was suddenly attacked in the early morning, while lying in bed, with acute pain in the lower part of the abdomen. She got up for an hour or so, but was compelled to go back on account of the increasing severity of the pain and tenderness of the abdomen. No rigor or vomiting. The pain gradually diminished, but a week later she began to vomit and this has continued more or less severely up to the present. She has also complained of difficulty and pain in micturition. Three weeks ago the

patient first noticed a swelling in the lower part of the abdomen and this has progressively increased in size and become more painful and tender. She has grown much thinner during the last few weeks and has kept her bed up to the time of her admission.

On admission the patient, a pale, emaciated woman with sunken eyes and looking extremely ill, complained of abdominal pain of six weeks' duration. Thoracic organs normal. The lower half of the abdomen is somewhat prominent and asymmetrical, the fulness being more marked on the right. The walls are somewhat rigid. On palpation a smooth, tender swelling can be defined reaching in the middle line to the umbilicus and laterally for a distance of three inches from the middle line. Indistinct sense of fluctuation was obtained. There is resonance over the upper half of the tumour. On bi-manual examination the uterus was found pushed forwards and to the left by two tense cysts, the larger one occupying the right posterior quarter of the pelvis, the smaller a similar position on the left, a distinct sulcus a little to the left of the median plane intervening. Temperature 101° to 102·8°. Urine normal.

On March 14th, six days after admission, the patient having been steadily losing ground and with a temperature ranging from 99·4° to 103·6°, abdominal section was performed. On the right side was found an inflamed ovarian cyst universally adherent and partly covered in front by adherent intestine. During the separation of the adhesion the cyst wall was ruptured and pus escaped freely. Sixteen fluid ounces of very offensive pus were drawn off by trocar and cannula. The vermiform appendix was so firmly adherent to the cyst wall that it was torn across during the separation of the cyst. It was thickened and inflamed, the lining membrane being denuded of epithelium and covered with lymph. On the left side there was a smaller cyst also intimately adherent to surrounding structures, especially to the rectum, and containing offensive pus which escaped in considerable quantity during its separation. The Fallopian tubes were normal. The peritoneal cavity was thoroughly doused with hot boracic lotion and two glass drainage-tubes inserted and the wound sutured with silk-worm-gut sutures. The operation lasted nearly two hours and the patient was returned to bed in a somewhat collapsed condition and an injection of brandy administered subcutaneously. The patient rallied well from the operation. The temperature rose the same night to 101°, but with that exception the maximum temperature during the convalescence, which was singularly rapid and uneventful, was 99·6°. One glass tube was removed the following morning and twenty-four hours later the other tube was replaced by an indiarubber tube, the discharge being purulent and offensive and containing small sloughs. Stitches were removed on the seventh day, the indiarubber tube on the fourteenth day, the discharge being very slight and non-offensive. She got up on the sixteenth day and left the ward well on April 13th. She presented herself a month later perfectly well.

CASE 3.—M. S.—, aged forty-six, married, was admitted into the Adelaide ward on Feb. 27th, 1892, complaining of attacks of abdominal pain of five years' duration. The patient has been married twenty-five years and has never been pregnant. Catamenia began at the age of fourteen, twenty-eight days' type, the flow lasting from three to four days and accompanied with pain. Since 1887 the patient has suffered from paroxysmal attacks of pain in the lower part of the abdomen and left side. She also suffers from winter cough. The attacks of pain recur very frequently and last generally for two or three days and always start in the left iliac region. During the attack she says she feels very ill and sick and is obliged to take to her bed. The longest interval that she has had free from pain during the past five years is five weeks. Between the attacks she feels quite well. She was in the ward under treatment for pelvic inflammation, chiefly cellulitic, twelve months ago and greatly improved whilst under observation, but from the time of her discharge she had suffered from recurrent attacks of pelvic pain more frequently than ever.

On admission the patient, a stout, robust-looking woman, complained of pain in the lower part of the abdomen and the left side. The abdominal wall was soft, thick and flaccid, resonant all over; nothing abnormal detected on palpation. On vaginal examination the uterus was found retroverted and displaced to the right. The sound passed normal distance. Occupying the left posterior quarter of the pelvis was a hard, irregular mass, quite fixed and somewhat painful. There was no evidence of fluctuation. The temperature was normal and

the urine contained a trace of albumen. The thoracic organs were normal. After seventeen days' complete rest in bed, there being then no alteration in the physical signs, abdominal section was performed. The left posterior quarter of the pelvis was found occupied by a tense, inflamed ovarian cyst roofed in by adherent intestine and omentum and partly covered in front by the thickened and inflamed left broad ligament. The uterus was displaced a little to the right of the median plane. Posteriorly, there were dense adhesions between the cyst and rectum. With considerable difficulty these adhesions were broken down and during the manipulations the cyst was ruptured and the purulent and highly offensive contents escaped into the abdomen. The collapsed cyst was then removed, a portion of its wall being left on the distal side of the ligature; the lining membrane of this was afterwards dissected away. The abdominal cavity was thoroughly doused with boracic lotion, a glass drainage-tube inserted and the wound sutured with silk-worm-gut sutures. On subsequent examination the cyst showed signs of intense inflammation; the wall was dense, a quarter of an inch in thickness and glistening white on section; it measured three inches and a half by four inches. Internally it presented a red, ulcerated and shreddy surface. At one part of the wall there was considerable thickening, which on section had the appearance of ovarian tissue rendered dense by chronic inflammation. It proved on further examination to be inflamed connective tissue, with the slightly thickened but otherwise normal Fallopian tube embedded in its midst. The convalescence was satisfactory in every respect. The patient got up on the fourteenth day and left the ward a fortnight later in good health, the wound having been completely healed for a week. The patient had since menstruated normally. There have been two attacks of severe pain of short duration, but the general health continues to improve. Some induration can still be felt on the left side of the pelvis.

CASE 4.—M. S.—, aged twenty-seven, married, was admitted into the Adelaide ward on Feb. 20th, 1892. She was married in 1880 at the age of sixteen and has had two children. She dates her illness from an abortion in 1885, after which she suffered from violent pain in the lower part of the abdomen with hæmorrhage and sickness for some months. During the past seven years the catamenial function, which had previously been regular and normal, has become very irregular, occurring at intervals varying from three to six weeks. She describes the flow as being like "dirty water." No dysmenorrhœa. She has not been pregnant since the abortion seven years ago. During these seven years she has been subject to attacks of abdominal pain. The last and most severe attack commenced a fortnight before admission. The pain was of a sharp burning character, situated chiefly in the right iliac region and to a less degree on the opposite side and radiating down the thighs. The patient had been in bed on account of the severity of the pain for one week before her admission.

On admission the abdominal wall was so rigid that a satisfactory examination could not be made. A few days later an examination was made under an anæsthetic; the uterus was found displaced to the left and freely movable. Occupying the right posterior quarter of the pelvis and depressing the right fornix was a tense, smooth, fluctuating swelling the size of a fist, separate from the uterus, which could be moved independently of it. The thoracic organs were normal. Urine contained a decided trace of albumen. Temperature 98° to 102°.

On March 18th abdominal section was performed. The uterus were found displaced to the left and the appendages on that side were normal; on the right side was found a globular tense cyst adherent to the surrounding parts and to the small intestine. The cyst burst during its separation from the adhesions and its purulent contents escaped partly into the abdomen and externally. The broad ligament was considerably thickened by cellulitis and the Fallopian tube was also thickened and inflamed. The tube, with the collapsed suppurating ovarian cyst, was removed and the abdominal cavity doused with boracic lotion at 110°. A glass drainage-tube was inserted and the wound sutured with silk-worm-gut sutures. On the following morning the glass tube was replaced by an indiarubber tube, the discharge being considerable in quantity and of offensive odour. The stitches were removed on the seventh day. The tube was left out on April 11th, there being less discharge of a purulent non-offensive character. The patient got up two days later and left the ward on April 29th, well, in all respects, except for the presence of a small discharging sinus at the lower angle of the incision.

(To be concluded.)

## BURTON-ON-TRENT INFIRMARY.

### A CASE OF INTESTINAL OBSTRUCTION WITH PECULIAR FEATURES.

(Under the care of Mr. P. B. MASON.)

THIS case presents features which make it of considerable importance, for it would appear from Mr. Mason's account that there was a giving way in the wall of the bladder of a "healthy muscular man" without unusual strain and without direct injury. There does not appear to have been any obstruction, such as stricture or enlarged prostate, to the outflow of urine, which itself is said to have been normal in character. The most marked change described is that in the bladder wall, the reason for the excessive thinness of which could not be found, though it was apparently the predisposing cause of the rupture. For the notes of the case we are indebted to Mr. R. M. Littler, house surgeon.

W. W.—, a healthy muscular man, twenty-nine years of age and unmarried, was admitted into this institution on May 20th last with the following history: Four days before admission, and when engaged in his ordinary avocation—furniture removing—he felt a sudden severe sickening pain in the abdomen which "doubled him up." Vomiting soon ensued and became bilious and later fecal. He described it as tasting "like what comes the other way." There was no action of the bowels and no passage of flatus. He had had previous attacks of pain in the abdomen for some weeks, which were said to be inflammation of the bowels. When admitted there had been no passage of flatus or feces since he was first taken ill and no vomiting for ten hours. The abdomen was rounded, tense and very tender. The pain specially referred to the region round the umbilicus, where there was some dullness. Pulse full and bounding, rate 80 to 90. Temperature 99.6°. The tongue was very dry and coated. He seemed very drowsy and had not the typical aspect of a patient suffering from peritonitis. He had passed urine at 4 A.M.; he also passed fourteen ounces at 3 P.M., quite clear. At 3.30 P.M. an incision about four inches long was made in the linea alba and the peritoneum exposed and opened. Distended small intestine presented itself and a little blood-stained fluid escaped. The coils of bowel were matted together with pieces of thick lymph. On further exploration with the finger, about half a pint of clear, fetid fluid came away, with a strong urinous odour. After washing the cavity out well an attempt was made to find the seat of constriction and the gut cleared for several feet in its congested and swollen portion, until clear, healthy bowel was found at each end. No definite constricting band was found. Rough fungating masses were felt in the left iliac region, feeling much like new growth, but it was not considered desirable to clear up this diagnosis by further exploration. The cavity was now well washed out, dried and stitched up. The patient bore the operation very well. He passed urine soon afterwards (eight ounces), clear and containing no albumen. Temperature at 5 P.M., 97.6°. He was very restless during the evening, but passed a quieter night. Nothing was given but ice and opium. The following day the temperature remained at 97.8°, but the pulse was weaker. Nutritive and brandy enemata were given and well retained. The patient did not complain of pain. Towards evening the temperature rose to 99.4° and he gradually got weaker, death taking place shortly before midnight. All the urine passed after the operation was clear and sweet, of normal colour and did not contain albumen.

*Necropsy.*—The small intestine was distended and evenly congested almost throughout. Coils were adherent to the anterior abdominal wall and to each other, but the adhesions were easily broken down. The inner surface of the pelvic peritoneum was covered throughout with a very thick layer of tough lymph. This also surrounded the appendices epiploicæ of the sigmoid flexure and probably gave rise to the sensation of new growth as felt at the operation. The bladder was covered thickly with lymph and collapsed and was isolated and removed with difficulty. On separating the layer of lymph before removal a small quantity of white purulent fluid appeared at its upper part and on examination after removal there was found a perforation in the bladder wall at its upper and back part about one inch by half an inch. The walls of this opening were, however, not at all congested or infiltrated and the surrounding bladder wall was very thin in places; only the mucous membrane was left. The kidneys and liver were

very congested. The pelvis of the left kidney contained a small quantity of purulent matter. The ureters were quite intact and healthy.

*Remarks by Mr. MASON.*—Although the operation in this case was useless, it is right to put on record all cases of laparotomy for intestinal obstruction. The condition found was very remarkable. The fluid referred to was undoubtedly decomposed urine contained in a sac formed by lymph matting together the small intestines. The intestines themselves had no collapsed portion, but antiperistalsis was no doubt set up by the mechanical interference caused by the adhesions of the various coils. When the urinous fluid escaped a catheter was passed into the bladder and a small quantity of urine drawn off exactly similar in character to that passed immediately before the operation. Post-mortem the condition of the bladder was remarkable in the thinning of its posterior wall, the muscular coat being much thinned and even absent in places. The actual opening was probably made while removing the thick layer of lymph which bound it down. The only explanation of the case which I can suggest is that a small sacculus of the bladder had ruptured and the extravasated urine had been confined by old adhesions among the intestines due to former attacks of peritonitis. It is sometimes impossible to explain why fluid in the peritoneal cavity does not pass certain limits, as in a case of laparotomy for ruptured liver which I have already recorded in THE LANCET. The effused and unclotted blood did not pass over the middle line or extend above the level of the umbilicus, while no adhesions were found on opening the peritoneum, the decubitus since the accident having been uniformly dorsal.

*Detachment of the Choroidæ.—Recurrent Keratitis Superficialis Punctata.—Changes in the Retina due to the contact of a metallic chip.—Double Optic Neuritis after Influenza.*

AN ordinary meeting of this Society was held on Thursday, June 9th, the President, Mr. Henry Power, F.R.C.S., in the chair.

Dr. STORY (Dublin) communicated the notes of a case of Detachment of the Choroidæ, which were read by the Secretary. The patient was a female aged twenty-four, the sight of whose right eye had failed twelve months previously; the eye subsequently became, according to her account, so painful that she wished to have it removed. It proved, however, that her statements on this point were exaggerated. On admission to hospital the vision of the right eye was reduced to counting fingers at one metre. On ophthalmoscopic examination it was observed that there was a large detachment of the retina below, extending from the margin of the optic disc downwards. No rent was visible in the retina; all over the detached portion were small, brilliant, white spots and also large, circular and linear white patches of degeneration. The choroid coat was also detached over a corresponding area; its structure could be easily made out through the overlying retina, except where the above-mentioned patches obstructed the view. The tension of the eye was normal and there were no external signs of disease. Reference was made to a case published by the author in the Society's Transactions last year.

Dr. ADOLF BRONNER (Bradford) recorded a case of Recurrent Keratitis Superficialis Punctata in which the use of cocaine aggravated the symptoms. The patient, a stout man aged forty-eight, first suffered from an attack in the right eye in March, 1867, and the disorder returned every year, usually in March or April and nearly always in the same eye. During an attack which occurred in 1885 cocaine drops were used and the consequence was an increase in the severity and duration of the attack. In March, 1892, the case first came into Dr. Bronner's hands, the symptoms, which had existed for a week, subsiding in five days under the use of atropine. As a result, however, of exposure to a strong wind the left eye became affected. There was severe pain in the eye and forehead, intense photophobia, the lids were red and swollen and there was much chemosis. The pupil was dilated and over the lower half of the cornea there were ten to fifteen small, white, elevated spots. The appli-

cation of cocaine produced two or three minutes' ease and then the old pain returned with increased severity, all the symptoms and appearances becoming exaggerated. After the subsidence of the attack the cornea was perfectly clear and there were no signs of macula. Somewhat similar cases had been recorded by several German authors and one also by Mr. Marcus Gunn in the Society's Transactions for 1890.—Mr. MARCUS GUNN referred to two cases he had brought before the Society a couple of years ago, soon after the condition was described by Fuchs. Treated by atropine followed by yellow ointment they recovered rapidly.

Mr. PRIESTLEY SMITH read a description of Changes in the Retina, due to the long-continued lodgment of a metallic chip on its surface, in a lad aged seventeen, who was struck in the left eye by a fragment of bell metal. When first seen one month after the accident a small linear cicatrix was visible at the inner margin of the cornea; behind this a black point in the iris probably indicated an aperture made by the chip. The lens was clear; the fragment of metal could be seen lying on the retina some distance from the nasal side of the disc and on a rather higher level. Its position was shown by a scotoma in the perimeter chart. The eye was free from pain or other symptoms and vision was  $\frac{1}{2}$ . About four months later the foreign body shifted its position to a slight extent, its heavier end moving slightly downwards; one month later the whole chip dropped directly downwards through an angle of about forty-five degrees, according to the chart. Its former position was marked by a grey opaque patch on the retina, around which was a cloudy zone bordered by a faint pigmentary discolouration. Two scotomata were now shown in the chart, the second one indicating the new position of the chip. Thirteen months after the accident the position of the foreign body remained unchanged; its surface was less lustrous than at first. On the chief arteries and veins of the retina were numerous minute shining points, looking like specks of gold-leaf. The eye remained free from pain or injection and the lad was regularly at work. Mr. Priestley Smith thought it unlikely that the eye would remain permanently in its present quiet and useful condition. The foreign body, though aseptic in the ordinary sense, was acting surely though slowly as a chemical irritant. The question as to the possible danger of this chemical action to the fellow eye is one concerning which further information is desirable.—The PRESIDENT referred to the case of a man who was struck in the eye by a chip from a hammer. Traumatic cataract resulted and after twelve years the eye was removed on account of attacks of severe pain. Great difficulty was experienced in dividing the optic nerve, which ultimately had to be done very far back, and it was then found that a large fragment of steel lay embedded in it. The eye itself had become quite blind, but no effect was noticed in the opposite one.—Mr. SNELL mentioned the case of a boy with a fragment of metal in one eye, but with retention of good vision. He considered it a matter of importance in such cases to keep the patient at rest in the recumbent position for some time after the accident, so that the chip might become fixed to the retina by the lymph thrown out around it.—Mr. TWEDDY spoke of a man who had been under his care about ten years ago, in whom a small chip of steel had passed through the cornea, iris and lens and had become embedded in the retina. The fragment became involved in grey lymph and the eye remained perfectly free from pain or irritation. The lens did not become opaque, although a fine scar was visible in it. The patient was seen at intervals for a twelvemonth afterwards.—Mr. CRITCHETT mentioned a somewhat similar case which he had had under observation for three years. The eye during that time remained quiet and vision was but slightly impaired.—Mr. LANG alluded to a case published by the late Mr. James Adams, in Vol. I. of the Society's Transactions. This patient had a foreign body embedded in the retina near the yellow spot. It was covered by lymph, which also extended along the vessels. After eight years the eye was still free from irritation and vision was  $\frac{3}{4}$ .—Mr. PRIESTLEY SMITH, in replying, contrasted these cases with those described in text-books associated with sympathetic ophthalmia and pointed out the enormous importance to practical surgeons of the fact that an aseptic particle could remain in and destroy one eye without affecting the other.

Mr. SIMON SNELL (Sheffield) read notes of two cases of Double Optic Neuritis after Influenza. Both patients were females, one aged nineteen, the other thirteen and a half. In each case sight failed a few weeks after recovery from an

attack of influenza. In the elder girl the neuritis had nearly passed off. When she first came under observation the optic discs were atrophied and there was no perception of light. The younger patient was seen three weeks after the sight began to fail; the neuritis was then well marked. Vision was in right eye  $\frac{2}{3}$ , in left eye  $\frac{1}{4}$ . The neuritis had now to a great extent cleared up, but the discs were atrophic and there had been very little improvement in sight. Mr. Snell referred to the cases published by Macnamara and Lee.—Mr. MARCUS GUNN mentioned a case under his care at Moorfields. The patient, a man of forty-five, had retro-bulbar neuritis; the discs were hazy and the vessels small and in one eye vision was entirely abolished. Recovery began in a couple of weeks, under mercury and iodide of potassium, the vision in the blind eye improving to  $\frac{3}{4}$ .—Mr. CROSS (Clifton) referred to two cases he had seen in young women, in whom there was no evidence of intracranial disease and nothing which seemed to bear a causal relation to the neuritis except influenza. In these cases vision failed rapidly within a few days of the attack.—Mr. MCHARDY mentioned two cases he had seen and which he considered were probably due to influenza, no other cause being ascertainable. Both were females and in both there was temporary albuminuria. He had treated them by absolute rest in bed and the administration of iron; recovery had ensued.

The following living and card specimens were shown:—

Dr. D. J. WOOD: Drawing of a case of Detachment of Retina, with Unusual Dilation of Retinal Veins.

Mr. J. GRIFFITH: Instrument for Removal of Meibomian Cysts of the Lower Lid.

Dr. REDMOND: Tuberculous Disease of Iris.

Mr. JULER: (1) Congenital Cleft of Upper Lid; (2) Congenital Dermoid Cyst.

Dr. JAMES ANDERSON: Paralysis of Third Nerve in a case of Migraine.

Mr. MARCUS GUNN: Ophthalmoscopic Drawing, showing changes in the Retinal Vessels in Chronic Albuminuria.

## EDINBURGH MEDICO - CHIRURGICAL SOCIETY.

WEDNESDAY, JUNE 22ND.

Dr. JOSEPH BELL, President, in the chair.

*Discussion on Pernicious Anæmia and its Treatment by Transfusion.*—At a special meeting of this Society on Wednesday, June 22nd, Dr. BRAKENRIDGE read a paper on the Treatment of Pernicious Anæmia by the Transfusion of Human Blood. Before proceeding to discuss the influence of transfusion the facts known and the views entertained regarding the disease were glanced at. "The facts recognised on all hands were—(1) the progressive and remarkable reduction in the number of the red corpuscles and alterations in their form and size &c.; (2) evidence of greatly increased destruction of blood-corpuscles in the liver; (3) evidences of altered genesis of red corpuscles in the blood-forming organs such as the marrow usually consisting of an over-production in number and an under-production in quality; (4) the condition is not definitely attributable to any ascertainable cause. Theoretically, the condition might be accounted for by (1) a faulty genesis, whereby the corpuscles were imperfect, deformed, delicate, short-lived and easily destroyed by the action of the ordinary blood-destroying organs—as the liver—or by any poison; (2) an over-activity and perhaps a modified activity in the organs which normally destroy worn-out corpuscles; (3) the presence of both factors as a result of the same disturbing cause; (4) by the presence of some poison, ptomaine or other, introduced through the alimentary canal or otherwise. While the disease arises independently, it may become engrafted on a wide variety of pre-existing diseases, as chlorosis, tape-worm, &c. Although many mines of information in the field of the pathology of the disease have recently been opened up and worked, and although some links have been successfully forged, a chain of evidence which will bind all the facts into one consistent theory has not yet been put together. There can be no doubt that the view entertained *a priori* regarding the probable nature of the disease will materially influence the expectation of success from such a remedy as transfusion of human blood. If we believe the explanation of the anæmia is to be found in a vicious activity of the blood-destroying organs, and particularly if we hold that this is

caused and aided by a blood-destroying poison absorbed from the alimentary canal, we could expect very little and very temporary assistance from the introduction of so small an amount of blood as from two to six ounces. If we believe, on the other hand, the explanation to be that owing to some modification of their function the blood-forming glandular organs have lost their power to produce healthy, properly constituted and normally long-lived corpuscles, our expectation of a beneficial result should be very much more hopeful, for we should expect the transfused blood would improve the condition both of the blood-forming organs and of the faulty blood-corpuscles. It was in the hope inspired by the latter view—which I held in 1885—that I determined to give transfusion a fair trial in all my cases which failed to respond to other and approved methods of treatment and from the outset I believed it might be necessary to repeat the operation. All the cases which responded to the ordinary treatment were excluded and only those which resisted all other methods were transfused. There are five such cases and they in some measure support the following conclusions: Firstly, that in the transfusion of human blood we have a powerful means of arresting the progress of this grave disease; secondly, that the operation in skilful hands and with due precautions is perfectly safe; thirdly, that a number of precautions must be attended to in performing transfusion if inconvenience and even risk to the patient are to be avoided; fourthly, that the results throw a suggestive side-light on the probable nature of the disease, supporting, although not shutting one up to the view that the anæmia is probably mainly due to a failure in blood genesis. But the purpose of this paper is therapeutical rather than pathological." The cases were given in detail.—Case 1. A woman aged thirty-four presented all the characteristic features of pernicious anæmia and on admission on June 19th, 1885, the red corpuscles were 1,900,000 per cubic millimetre, and the hæmoglobin 35 per cent. She was carefully and specially dieted and treated with citrate of quinine and iron with arsenic. On June 28th the hæmoglobin had fallen to 30 per cent. and the red corpuscles to 1,600,000 per cubic millimetre. On July 3rd the iron and quinine were stopped, as they were not agreeing with the patient, but the arsenic was continued. On July 5th the hæmoglobin had further fallen to 24 per cent. and the red corpuscles to 1,160,000 per cubic millimetre. The temperature from the first ranged from 99° to 100·8°. The unanimous opinion of the physicians who saw the case was that it was one of pernicious anæmia and the question to him was, Could anything further be done? He held then, as he still holds, that the disease was mainly due to faulty genesis and a consequent tendency to the early death of the corpuscles in the blood-destroying organs, and he determined to try the effect of repeated transfusions in the hope that the normal function of the blood-forming organs might thereby be restored, or that such an impetus might be given to them as would bring them within the influence of the curative action of arsenic. After full and careful consideration and discussion of the matter with Dr. John Duncan transfusion was determined upon. The method employed was the indirect one; the blood was received into a solution of 1 in 20 phosphate of soda and maintained at blood heat. Six ounces of blood with two ounces of the phosphate of soda solution were injected very slowly, the pulse and respiration being carefully watched and the injection being suspended when any marked change in either was noted. Seven hours after the transfusion the patient felt better, the pulse was increased in volume and the blood-corpuscles had risen from 1,160,000 to 1,470,000 per cubic millimetre. There was a slight upward tendency in the number of corpuscles and the amount of hæmoglobin for three days and then there was a rapid fall until five days after the transfusion; they were nearly as low as before it. The second transfusion was done on July 12th and after it the corpuscles were 1,670,000 per cubic millimetre. The third transfusion was on July 26th, the corpuscles at that date having risen to 2,215,000 before the operation and to 2,820,000 after it. A fourth transfusion was unsatisfactory, the soda solution being used too strong and she declined to submit again to the operation. When she left the hospital the blood-corpuscles had trebled, being 3,000,000 per cubic millimetre and the hæmoglobin having risen to 60 per cent., her strength and colour having greatly improved. She returned to her home and died at the end of the year. From about four or five days after the first transfusion microcytes disappeared from the blood and were never again seen.—Case 2. A married woman. The red corpuscles on Oct. 11th, 1888, numbered 1,000,000 per cubic millimetre and the hæmoglobin was 20 per cent. During the

first six days in hospital the corpuscles rose to 1,900,000 per cubic millimetre, but during the subsequent seven days they fell to 960,000. On Oct. 27th arsenic was commenced and in two days the corpuscles rose to 1,100,000, after which they gradually fell and reached 640,000. On Nov. 2nd, with the corpuscles at 640,000 per cubic millimetre, she was transfused, about five ounces of blood being used. After transfusion the corpuscles numbered 1,030,000 and from this time there was a steady rise. In seven days they had reached 2,080,000 and before she left hospital they had risen to 4,000,000 per cubic millimetre and the hæmoglobin to 75 per cent. of its normal; while the temperature, which had ranged from 99° to 101°, fell soon after transfusion to normal. She has remained quite well since that time. The particulars of the other three cases need not be given, for in the case of two of them the effect upon the blood was the same, although in both accidents of an avoidable nature occurred and in the other case transfusion was delayed too long. In all the cases transfusion not only increased the number of blood-corpuscles immediately, but the corpuscles continued to increase after each transfusion. It was necessary to take great care in all the steps of the proceeding and the operation had to be performed very slowly, and with full attention to all precautions the operation does not entail any danger to the patient.

Dr. AFFLECK then read the notes of a case of Pernicious Anæmia and showed the patient, in whose case he had, as a *dernier ressort*, used transfusion, although he had at the time little if any faith in the treatment. However, this case had entirely changed his views, for the patient had made an uninterrupted recovery after one transfusion, the corpuscles reaching their normal limit in six weeks.—Dr. JOHN DUNCAN referred to the surgical aspects of transfusion and said that after trying all methods he preferred the phosphate of soda method which had been suggested by Dr. Pavy and brought under his notice by Dr. Cotterill. He had used it extensively in his surgical operations with the happiest results. He dwelt upon the precautions necessary in the preparation and sterilising of the soda solution and explained how the accidents had happened in Dr. Brakenridge's cases. He thought that the rigor which occurred in some cases was not necessarily septic. He considered one-third of the soda solution the best proportion to use. Whatever constituent of the blood be useful in these cases of anæmia, it is permissible to believe—(1) that all of them when injected are still visible; (2) that, as with skin, bone and nerve, healthy blood tissue may have a determining influence in producing its like; (3) that the introduction of blood in cases of hæmorrhage is more valuable bulk for bulk than that of saline solution; and (4) that the cases prove that with little risk a beneficial effect in anæmia is produced by the operation.—Dr. JAMES asked whether the disease might not be due to a parasite of some kind and if the transfusion of blood serum might not be sufficient to counteract the poison.—Dr. W. RUSSELL referred to a paper he had published in 1889, in which he contended that there was a hyperplasia of blood-forming tissue which was to be regarded as a compensatory process; and that there was evidence of increased blood destruction in the liver, spleen and kidneys, but that for various reasons he did not consider the disease was a liver disease, although this view was at first sight attractive. Beyond the two facts of increased destruction and increase in blood-forming tissue he held, then, that we could not go. The question now was whether Dr. Brakenridge's remarkable results and work in other fields enabled them to move forward in their views and he thought they did. Dr. Brakenridge's and Dr. Affleck's cases clearly established the fact that transfusion had a curative effect, the corpuscular richness continuing to rise after the added corpuscles must have perished. On the other hand, within a few years serum therapeutics had arisen and was practically a new science. The curative action of blood serum under certain conditions was fully established, and knowing the results being obtained in pernicious anæmia by Dr. Brakenridge, it had been before his mind for some time that Dr. James's suggestion was in the right direction; and he believed the disease would be found to be an infective one, which the transfusion of blood counteracted, whether it did so by its antitoxic effect or by its influence upon phagocytic action; and if this view were correct, Dr. James's further suggestion that blood serum might be sufficient would probably also be correct. There still would remain the question whether the disease was due to an organism in the blood or, as Hunter believed, to the absorption of ptomaines from the intestinal tract and in view of the

cases brought before the Society he thought the former would probably be the correct view. The view held by Dr. Brakenridge did not appeal to him as it did to Dr. Brakenridge, while the infective view fitted all the facts better and was in accordance with recent work.—Dr. SMART, referring to clinical work which he was at present carrying on in the Royal Infirmary with reference to the pathology and treatment of anæmia, said that he had been particularly interested in one feature to which his attention had been specially drawn and which had a distinct reference to the present discussion. The urine in all his anæmic patients yielded a hæmatine reaction by means of a test suggested by MacMunn in his book on the Clinical Chemistry of the Urine. These urines do not afford any ocular evidence of the presence of blood, many of them being pale and colourless. The characteristic roseate colour appears only after the addition of the test. The explanation given of this phenomenon by MacMunn is that the colouring matter is derived from the destruction of the red corpuscles of the blood, brought about by the absorption from the bowel of decomposing fecal matter, which would appear to break up and destroy them, causing anæmia. The results of his examinations of these urines would seem to corroborate this view. He also made examinations of urines in cases of chronic constipation and in one case of intestinal obstruction of nearly a month's duration, in all of which the colour reaction was very pronounced. If the view be correct that the red corpuscles undergo destruction in the circulation by a process of auto-blood-poisoning it can hardly be doubted that the blood-making organs also participate in the general sepsis. This is rendered highly probable in pernicious anæmia by the evident great depreciation in number of the red corpuscles, as also by their altered shapes and low standard of hæmoglobin—all indicative of the extreme disability of the formative blood organs to provide the number or quality of the corpuscles required for the needs of a healthy vitality. If we admit that in pernicious anæmia there exists this twofold disability, the one destructive and the other a constructive defect, we are at a better standpoint to appreciate the effects which followed the transfusions of healthy blood, as referred to by Dr. Brakenridge in his cases and as seen in Dr. Affleck's patient, who had only four ounces of blood injected. The remarkable effects which followed cannot on any theory be explained by reference to the quantity of blood used. It will be more accordant with our knowledge and experience to ascribe these effects to the energetic action of healthy blood, viewed in the circumstances, as a most potent therapeutical agent, stimulating to the utmost the devitalised organs and tissues and rousing them into renewed and sustained activity, and, most of all, by affording to the trophic and other centres concerned in blood making that kind of degree of stimulation which they most stand in need of. Dr. Brakenridge's work on transfusion is of great value in settling the question of its eligibility as a method of treatment. After the results obtained we must regard it as a remedy of high rank, whether as given primarily, or after the apparent failure of other remedies.—Dr. JAMES RITCHIE also referred to different forms of anæmia and in particular to a family in which several infants had died of what he believed to be pernicious anæmia, in one of whom the body was examined and there was evidence of blood destruction in the liver.—Dr. R. MUIR said that he also had found evidence of blood destruction in the liver and that he agreed with the views expressed by Drs. James and Russell.—Dr. COTTERILL spoke to the advantages of the phosphate of soda method of transfusion and Dr. NORMAN WALKER as to the importance of thorough sterilisation.—Dr. BRAKENRIDGE, in his reply, said that the purpose of his paper was mainly therapeutic and while he still held by his original view as to its pathology, he by no means felt bound by it.

At the June quarterly meeting of the Court of Assistants of the Society of Apothecaries the following gentlemen were elected members of that Court: Dr. J. S. Stocker, Dr. T. Dickinson and Sir George Buchanan, F.R.S., late Medical Officer, H.M. Local Government Board. Dr. Stocker has been for some years past the chairman of the Society's Examiners and has greatly contributed in that capacity to the successful working of the Medical Act of 1886, so far as relates to the granting of a complete qualification by the Society. At the same Court Sir Hugh Reeve Beever, Bart., King's College Hospital, was elected one of the Society's Examiners in the place of Dr. Stocker.

## Reviews and Notices of Books.

*The Principles and Practice of Medicine.* Designed for the Use of Practitioners and Students of Medicine. By WILLIAM OSLER, M.D., F.R.C.P., Professor of Medicine in the Johns Hopkins University, Physician-in-Chief to the Johns Hopkins Hospital, Baltimore, formerly Professor of the Institutes of Medicine, McGill University, Montreal, &c. Edinburgh and London: Young J. Pentland. 1892.

THIS book is a distinct acquisition to medical literature. There are plenty of works on the principles and practice of physic, but there is always room for one more which bears the notes of personal experience, keen observation, boundless trouble, power of lucid and systematic statement, and interest in disease and its processes. Indications of these qualities are to be found in every part and article of this book, which we most heartily commend to students and practitioners of medicine. Though an American Professor, Dr. Osler is no stranger in England. He is well known to English pathologists and physicians by his Gulstonian Lectures, delivered in the Royal College of Physicians of London in 1885 during the presidency of Sir William Jenner on Malignant Endocarditis, and throughout this volume he does ample justice to the work of the British School of Medicine. The author arranges his subjects in the following order of sections:—Section 1 deals with Specific Infectious Diseases; Section 2, Constitutional Diseases; Section 3, Diseases of the Digestive System; Section 4, Diseases of the Respiratory System; Section 5, Diseases of the Circulatory System; Section 6, Diseases of the Blood and Ductless Glands; Section 7, Diseases of the Kidneys; Section 8, Diseases of the Nervous System; Section 9, Diseases of the Muscles; Section 10, the Intoxications, Sunstroke, Obesity; Section 11, Diseases due to Animal Parasites. There are various charts and illustrations interspersed throughout the book which add to its value. The extent to which the author contrives to give the latest investigations in pathology and to combine with this such an admirable account of his own large clinical observations is striking. The boldness, too, with which he accepts new conceptions of any given disease or places it under a new classification shows at once his acquaintance with the latest tendencies of medical science and the openness of his mind for the recognition of new truth. As an illustration of this we may refer to his article on Pneumonia, extending over twenty-six pages, in which every symptom, feature and relation of the disease is very graphically described. But the qualities of the author to which we have alluded as illustrated in this article appear in the opening definition of the disease:—"Pneumonia: an infectious disease characterised by inflammation of the lungs and constitutional disturbance of varying intensity. The fever terminates abruptly by crisis. Secondary infective processes are common. An organism, the *diplococcus pneumoniae*, is invariably found in the diseased lung." Who can deny to the author of such a definition of pneumonia his opinions and the courage of them?

We are by no means convinced that all pneumonias are of an infective character and we think that Dr. Osler is a little hasty in including all of them under such a definition. We still adhere to the belief that in many, if not the majority of cases of the disease, exposure to cold and not infection is the main causative agency, judging by common evidence. But this does not affect the ability with which Dr. Osler adduces and enforces the evidence of its dependence in many, if not all, cases on a micro-organism, the *diplococcus pneumoniae*. Be this as it may, his clinical description of the disease and the account he gives of the very interesting studies of the Drs. Klemperer of Leyden on the production of immunity from pneumonia in animals by the subcutaneous or intravenous injections of large quantities of the filtered bouillon cultures,

or by injection of the glycerite extract, and on the cure of it in infected animals by injection of the serum of an animal that had been rendered immune, give this chapter of the book a very complete character, embracing all that is suggestive in recent research and all that is to be learnt by close personal and clinical observation. Amongst the latter is his account of the complications met with in the disease and of the results ascertained in 100 necropsies. We notice too more than one thoughtful allusion to a point not made so clear in books or so well realised in practice as it should be—the “agonising” character of the pain of pneumonia.

Tuberculosis in all its forms is classed among the specific infectious diseases, and receives the attention it deserves as one of the most widespread of maladies that has recently received brilliant elucidation. Under this heading, too, the articles Pericarditis and Endocarditis in Section 5—including one on Malignant Endocarditis—and the articles on Chronic Valvular Disease are extremely valuable for their lucidity and the personal observations clinical and post mortem, which they include.

There is always one question which is vital in a work on the practice of medicine: What are the “lights” of the author in regard to therapeutical measures? It has to be admitted that the closest student of symptoms and of lesions is not always the author from whose book the practitioner in his difficulties will obtain the greatest help. Dr. Osler’s belief in mere drugs is very qualified. He does not believe, for example, that the course of pneumonia can be modified by medicine. And we are disposed to think that he over-estimates the necessary fatality of it. But still he is full of wise counsel as to the help that physicians can give; and where medicine is specific he has ample generosity to recognise it. Thus of quinine in ague he says: “In not a single instance among the several hundred cases of intermittent fever which I have had under observation during the past seven years did quinine fail to check the paroxysms”; and he supplements this broad statement with interesting details of dose and mode of administration. We congratulate our brethren of the American school on a work on the practice of medicine which deals with this great subject in a most fitting manner.

*The Principles of Bacteriology: a Practical Manual for Students.* By A. C. ABBOTT, M.D., First Assistant, Laboratory of Hygiene, University of Pennsylvania, Philadelphia. With Illustrations. London: H. K. Lewis. 1892.

In the handy little volume before us are contained most of the directions essential for the carrying on of bacteriological investigation. After giving an introduction and general chapters on bacteria, their nutrition and their products, the author deals with the principles of sterilisation, disinfection and the apparatus required for the carrying out of these processes. The principles of Koch’s plate method of isolation are described, after which descriptions of the various media on which micro-organisms may be grown and the different methods of employing these are given clearly and succinctly. Staining methods, inoculation, post-mortem examination and the like are taken up in turn; then a scheme of identification is appended; this, however, is far from complete and will be of comparatively little use to those who are not already acquainted with the methods of determining species, though we find that here the use of a most important medium (milk) is, very properly, strongly insisted upon—a medium which has hitherto been far too little recognised.

In the portion of the work devoted to the practical application of the methods of bacteriology we find a series of graduated lessons which should be of use to those who are studying bacteriology without a teacher. The whole book is evidently the work of an observer who has had considerable

laboratory experience; there is little that is superfluous and much of what he has written is exceedingly good. It is, however, somewhat one-sided, as too much stress is laid on the German methods and too little on those in use in France. It is a capital text-book for students, though it is not equal to “Salomonsen’s Bacteriological Technique” (a work which was also translated and first printed and published in America) either in originality or thoroughness. The printing is good, but several Americanisms met with in the text strike the eye of the English reader.

*The Human Mind: a Text-book of Psychology.* By JAMES SULLY, M.A., LL.D. London: Longmans, Green and Co. 1892.

THE author of this work has an established reputation as a psychologist, and his “Outlines of Psychology” must be familiar to a large circle of students. His present attempt is more ambitious and is characterised by thoroughness of detail and systematic analysis of mental phenomena. The book is one which shows how great an advance has been made in the study of this subject by the aid of modern physiology, and Dr. Sully has contrived to clearly expound the nexus between the higher intellectual attributes and those of sensorial activity. The first part of the work forms a series of introductory chapters treating of the nature and scope of psychology, its data and method and a discussion on the physical basis of mental life. In the last named there is an outline sketch of the nervous system, which is hardly adequate to the subject, and to a student who has no previous physiological training it may even prove misleading. The author indeed refers the reader to physiological text-books and says he only offers a *résumé* of the more important points having a psycho-physical significance. Later on, in speaking of “localisation,” he points out that it is yet far from complete, but he gives no indication of the fact that there are whole areas of the cerebral cortex which are as yet unexplored, or rather the stimulation of which excites no response capable of being interpreted. No doubt in the future, as in the past, clinical and pathological observation may come to the aid of physiology in this matter; and the various psychoses may come to be associated with definite changes in cortical areas. In the gradual unfolding of his subject the author proceeds step by step in a manner which deserves the highest commendation. Thus the second part of his work is entitled “General View of Mind.” It opens with an analysis of mind, in which the triple functions of intellect, feeling and will are first analysed and the relations of these mental processes to physiological functions discussed. He passes on in the next chapter—that on Primitive Psychological Elements—to deal with sensations in the first place, and then in turn with “elements of feeling,” “active elements,” and “primitive psycho-physical complications,” which include the subject of Instinct. To us the first of these is most attractive, as it is based on the definite results of scientific research; and Dr. Sully shows how thoroughly he has grasped the physiology of sensation and the senses in the full exposition he gives of them. Of especial interest are the sections devoted to hearing, sight, and the muscular sense. The mental response to sensory stimulation or the mental images of sensations is a subject of some complexity, and it is skilfully treated under the head “Attention” in the chapter that follows next upon the discussion of Sensations. Analysing this still further, we are taken to the processes of mental differentiation or discrimination, then those of assimilation, and lastly of association, and the evolution of these factors of mental elaboration is shown to be generally in harmony with physiological development. The way is now cleared for the fuller exposition of each of the three great divisions of the mind, and to this exposition about two-thirds of the work are devoted. We do not propose to follow the author

in his analysis of intellect, feeling and volition. The whole range of psychological problems is here presented with a clearness and precision that seldom characterise their discussion. Nor is his exposition limited entirely by the normal, for towards the close he speaks, briefly it is true, of hypnotism and mental disturbances, showing how the transition from the healthy to the morbid takes place in the sphere of mind as imperceptibly as it does in physical conditions. We must be content with warmly commending this book to students and to members of our profession. They will find it of no small service in practical life, whilst the problems it raises and the explanations it affords give opportunity for unlimited reflection and thought upon matters that have been too often obscured by fanciful theories and too much neglected by those whose duty it is to promote the health of the mind as well as of the body.

*A Treatise on the Parasites and Parasitic Diseases of the Domesticated Animals.* By L. G. NEUMANN. Translated and edited by GEORGE FLEMING, C.B., LL.D., F.R.C.V.S. London: Baillière, Tindall and Cox. New York: William R. Jenkins. 1892.

HELMINTHOLOGY, in common with every department of science bearing on the practice of medicine, has of late years undergone enormous expansion; so much so that it is quite impossible for the medical man, with so many other things to attend to, to keep abreast with its progress. A competent knowledge even of the comparatively small department of the science which has immediate reference to man himself is possessed by very few and anything like a fair knowledge of comparative helminthology by fewer still. Yet medical science is daily becoming more and more the study of parasites and comparative pathology is daily being more and more drawn on to illuminate and advance human pathology. The appearance therefore of an important work of reference dealing with questions of comparative pathology is a matter of interest to the medical as well as to any other profession to which it may happen to be more especially addressed. Neumann's work is of this character and it is not too much to say that the distinguished author and, in a secondary degree, his translator have placed the medical profession under very heavy obligations.

Neumann arranges his subject, not on strictly zoological but rather on anatomical and pathological principles. This, we are sure, will be found a very great practical convenience. Such a plan enables the comparatively uninitiated observer to identify species very readily and with certainty and—guided by the copious bibliography, which is practically complete—to find out all that is known about any given parasite. Further, by bringing similar forms of helminthiasis in different species into close contrast a fuller and more philosophical grasp of any given helminthological problem is quickly obtained.

In carrying out this plan the author divides his subject into the Parasites of the Skin, the Parasites of the Digestive Apparatus, the Parasites of the Serous Membranes and so forth. So that a student, wishing to identify a parasite which he may have found or is submitted to him, has only to turn to the chapter on the particular part of the body from which the parasite came to learn all about it or to find out where to get fuller information. Thus, suppose we are concerned with a distom from the lungs of an ox, we turn to the chapter on the Parasites of the Respiratory Apparatus, Article II, where, under the heading Distomatosis, we find not only an account of the distoms of the ox's lungs, but an account of the distomatoses of the lungs of other domesticated animals, and in footnotes references to the entire literature of the subject. The chapter on the Acariases of the domesticated animals is particularly full and well done and the section on the dermatomycoses is particularly interesting to medical men.

Subjects having a special bearing on human pathology,

such as coccidiosis, trichinosis, hydatid disease, &c., are admirably handled, and to the human pathologist are of very special interest. In these and other chapters it will be found that many interesting and valuable side lights are thrown on questions of human pathology. We do not hesitate to say that this is a work which all pathologists ought to possess; and the practitioner, especially the country practitioner, who is so often looked on as encyclopædian in his knowledge of physical science, will not fail to add to his reputation if he has this book on his shelves and uses it.

Dr. Fleming, although himself well qualified to write a work on the parasitology of the domestic animals, has, with rare modesty, preferred the task of translator to that of author. It is unnecessary to say that he has performed his self-imposed task with complete success, besides contributing many original notes which will be found interpolated here and there throughout the text. Veterinary surgeons already owe much to Dr. Fleming; by the present work their debt, as well as ours, is still further increased.

## Analytical Records.

### AUSTRALIAN BRANDY FROM THE VICTORIAN VINEYARDS. (HOWES & EDWARDS & SONS, 27, MINING-LANE, E.C.)

OUR large colony, Australia, much to her credit, produces many good things and now, it would appear, she promises to vie with countries of established reputation in the production of not only excellent clarets, burgundies and ports, but also of sound, honest brandy. We have received a sample of a consignment of brandy recently shipped from Melbourne which our analysis and examination show to be of a fragrance, purity and quality second to none. The importance of this new departure can hardly be over-estimated when we are confronted with the fact that genuine grape brandy has, according to many official reports, become almost a thing of the past. In 1890 the vice-consul at Rochelle warned the British public that real cognac was then scarcely obtainable and what was sold as such was usually spurious. This statement of course caused much annoyance in the Charente district, where alone cognac is made, and sundry contradictions were published; but the consul, Mr. Warburton, in a more recent report, adheres to it and says that little as there was before of cognac brandy, there is less now. What is sold as cognac at a lower price than 25 francs per bottle is not cognac at all, but an industrial rather than an agricultural product, into the composition of which cognac, even if present, enters only to a very limited extent. Since the unfortunate ravages of the phylloxera there has been an immense falling-off in the shipments of brandy from the cognac district. It is a significant fact, however, that in the importation of so-called brandy there has been no falling off whatever and there is little doubt that the term "brandy" (branntwein) is now extended in its application so as to include spirit distilled from maize, rice and other cereals, as well as from potatoes, turnips and beetroots. The introduction of a genuine grape brandy, therefore, more particularly from our own dependencies, is a matter not merely of commercial importance, but one of especial interest to medical men, who have oftentimes to resort to it as a most valuable and powerful remedial agent. Just as it is essential that drugs (as, for example, salicylic acid) should be pure, so also, for medical use, it is essential that brandy should be pure. The fragrance, flavour and character of the Australian specimen submitted to us were excellent and the results of analysis testify further to the genuineness of the product. The alcoholic strength, as will be seen, is greatly

in excess of that of ordinary brandy. It was equal to 51·80 per cent. absolute alcohol by weight, or 59·65 per cent. by volume, or, in terms of proof spirit, 104·5. The residue amounted to 1·06 per cent. (almost exactly equal to real cognac) and on burning gave off a fragrant ethereal smell. A mere trace of ash remained. We confidently bring this new and interesting colonial product to the notice of the profession and it would be satisfactory to learn how in its therapeutic action it is found to differ from brandy now commonly met with.

#### MOUNT ROSA HONEY.

(AGENTS: S. DE PINTO & SON, 5, COMMERCIAL-STREET, LEITH.)

This is described as perfectly pure honey, gathered by bees from the highest flora in Europe, in ambulant apiaries placed on the slopes of the southern or Italian side of Mount Rosa. Our analysis does not disagree with the former part of this statement. We found the honey to be of a clear, brilliant straw colour and of excellent aroma and taste. Analysis showed it to contain about two-thirds its weight of glucose and other honey sugars, the rest of the solid constituents, amounting to 11 per cent., consisting of wax, pollen and gum.

#### GAUFRETTES FRANCAISES.

(H. A. SCHLESINGER, 81, JEWRY-STREET, E.C.)

The skill of the French biscuit baker is eminently displayed in these preparations. They consist of a thin, delicately crisp and nutritive biscuit, flavoured agreeably with vanilla. As very little effort is required to masticate them, they are admirably suited as accompaniments to the light meal of a convalescent or invalid.

#### CAFFYN'S CARNIS SUPPOSITORIES.

(LIQUOR CARNIS COMPANY, LIMITED, 50, HOLBORN VIADUCT.)

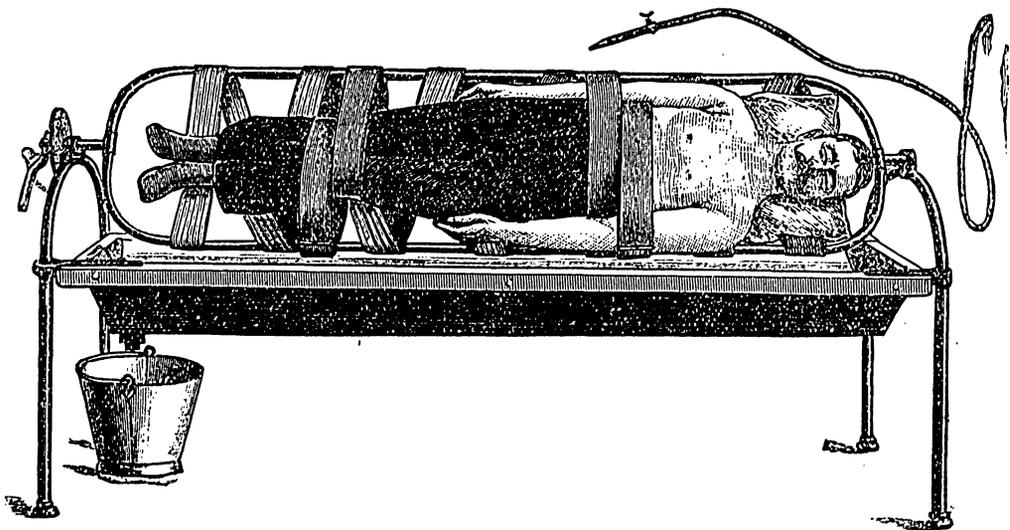

These preparations contain an equivalent of two drachms of liquor carnis and they appear to fulfil the requirements of a satisfactory suppository. They contain, for instance, according to our examination, the soluble albumen of freshly expressed meat juice and they melt readily in water at the normal temperature of the rectum in about five minutes, without the assistance of agitation or stirring. Inasmuch as unaltered albumen of meat juice is absorbed in the rectum to nearly the same extent as complete peptones, the value of these suppositories will be obvious to every practitioner. They are bullet-shaped and contain the nutrient material in a moist and adaptable colloid medium, which keeps well on account of the presence of a mild antiseptic.

## New Inventions.

### REVOLVING TABLE FOR FLUSHING OPERATIONS.

On May 24th, 1892, I exhibited this table in the operating theatre of the Westminster Hospital and used it for the following cases:—1. Excision of the left mamma. 2. Excision of segment of bone at transverse tarsal joint. 3. Excision of right hip-joint. 4. Radical cure of inguinal hernia. The engraving gives a good general idea of the table. The top

infected bands are burnt. Broad leathern straps belt the patient down and permit his body to be subverted. Underneath this framework is a large, long, japanned trough, which leads down to the foot of the table through a tap or plug into a bucket and prevents the operating floor becoming slippery from moisture or unpleasant from mess. A hose is shown in the engraving capable of supplying pure water or medicated solutions direct to the wound. The table stands firm. It has been manufactured by Mr. John Carter, 6 A, New Cavendish-street, W., at a cost of ten guineas. The workmanship is good and much care has been bestowed on its

revolving frame can be fixed at any angle, or easily detached and used as a stretcher for the conveyance of a patient from and to the ward. The capability of revolving allows the freest drainage by rendering any wound dependent and permits the fullest examination in varying posture. The framework is turned by a short lever and fixed by a steel pin at the foot of the table. The patient reclines upon broad canvas bands; these cross bands are quickly adjusted and can be replaced (if soiled) at the cost of one shilling. Thus all

execution. The table has been presented to the hospital by a lady (per J. A. Tapson, Esq.). It is thought that this description of table goes some way towards meeting a general surgical want—not only for major operations and interference with the body cavities, but also for the ordinary dressings in surgery, where cleanliness and the very free use of good water is necessary.

RICHARD DAVY, F.R.C.S. Eng.,

Welbeck-street, W.

Surgeon to the Westminster Hospital.

TEAPOTS.

WE have had submitted to us specimens of two teapots, each of which supplies, in its own way, a very important want. "Tea," says Sir Andrew Clark, "is a blessed beverage," and we feel sure that many will re-echo the sentiment, but it is one that only applies under certain conditions of its preparation. Some teas are speedily converted by imperfect methods of preparing them into the representation of all that is "physiologically wicked." For instance, tea is a very common cause of palpitation, which is probably due to the theine or caffeine in its composition which increases the power of the cardiac muscular fibre and stimulates it to increased contraction. Indigestion and other

FIG. 1.

troubles are only too common among inveterate and unwise tea-drinkers. On the other hand, everyone who knows the refreshing and invigorating power of tea, when taken and prepared judiciously, will admit the importance of any invention or modification which tends to render it non-injurious. The fault in many instances is not so much with tea *per se* as with our method of making the infusion in this country, the long-continued "drawing" to which it is generally subjected lessening the aroma and extracting so much of the soluble matters, that the resulting fluid is less aromatic and delicate in flavour and at the same

FIG. 2.

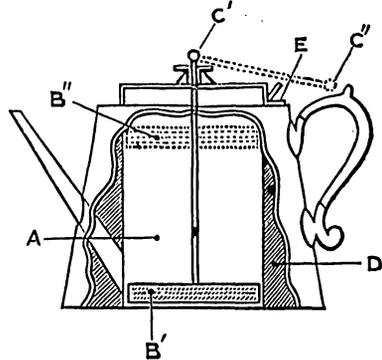

time a too great quantity of tannin is dissolved out, more especially from the fashionable Indian teas. The first teapot is sent to us by the patentee, Mr. J. A. Chandler, who has had upwards of twenty-five years' experience in the Mincing-lane tea trade. It is a combined teapot, infuser and strainer. The modification consists in a little cage attached to a chain, which pierces a hole in the lid of the teapot and by which the cage is raised or lowered in a manner very similar to the "centre board" of a yacht; when this has been charged with the tea it is allowed to be suspended in the hot water and pulled up by means of the chain

when the infusion is made. The idea was recommended by Sir Andrew Clark many years ago. By its use the tea cannot be stewed or over-drawn, for, when the time necessary to its infusion has expired, the cage can be pulled up out of the water, and the tea will then remain uninjured. By this teapot the minimum quantity of tannin is obtained and very perfect infusion of the tea is ensured. The urns are fitted with an extra lining or cosy to prevent the outward radiation of heat. The patent includes a complete infusing apparatus, which can be applied to any ordinary teapot. The teapot is made of the best quality of material and when it can be had in porcelain will certainly be a valuable and useful article for the tea table, and a few modifications, which will no doubt be made, may greatly add to the importance of this new application of an old and well-known principle. Information can be obtained at the offices of the patentee, 21, Bedford-street, Strand.

The second teapot, which we illustrate, is made by Mr. G. Wilson of Paul-street, London, E. C., and it combines, as will be seen by the illustration, some very important principles, although the application of them is still in a crude form. Hitherto our appliances for making tea have been more elegant than scientific, but the teapot figured here is on a sounder basis. The diagrammatic sketch sufficiently explains the principle.

FIG. 3.

A, Teapot proper; B, tray for tealeaves in position for infusing; B', tray for tealeaves drawn clear of the water; C, rod for drawing up tray; C', rod for drawing up tray, with tray drawn up; D, hot-water chamber surrounding teapot; E, funnel-opening for filling D.

Boiling water is first poured into the outer chamber D, to heat the teapot and then the tea is made in the ordinary way, but after standing for from three to four minutes the tray is drawn up into the top of the teapot by means of the jointed rod C, and the infusion ceases, the result being a perfectly clear, palatable and wholesome beverage which will remain hot for a considerable time and yet be as delicate in flavour and as harmless as when first infused. This, like the other teapot, would be improved by being manufactured in porcelain.

**BEACH ROCKS CONVALESCENT HOME, SANDGATE.**—The new convalescent home at Sandgate was formally opened on Saturday, June 25th, by Sir Edward Watkin and Lady Ingram Watkin in the presence of a large assembly of the inhabitants of the town and of visitors from other districts interested in the work of the Samaritan Society. It is pleasantly situated close to the sea, which it faces and which is approached by broad flights of steps from its terraces. Being thus open to the invigorating and health-giving sea-breezes, it is sheltered on the north and east by the well-wooded heights of Shorncliffe. The building and the furniture have cost in all about £20,000. It has been the aim of the designers to get as much light and air within the building as possible, which must tend to have a most salutary effect on many of the patients who unhappily have been accustomed to different surroundings. It is already occupied by 130 inmates.

# THE LANCET.

LONDON: SATURDAY, JULY 2, 1892.

THE report of the House of Lords' Committee upon Metropolitan Hospitals will serve to form a somewhat diffuse discussion and to give point to a controversy which up to the present time has ranged in a more or less confused way over an immense field of debate. This feature of the position is strikingly illustrated in the *procès* of evidence which the report contains, but which, owing to pressure on our space, we are unable to reproduce to-day. The digest brings into a manageable compass the substance of the very voluminous evidence laid before the Committee and, by means of the Committee's earlier reports, before the public. But it thereby serves to make manifest the great number and diversity of the points to which that evidence has been directed and to give an impression even stronger than that produced by the unabridged evidence of the multiplicity of the issues raised. Upon many of these issues the Committee has not adjudicated in any way and in that sense the report therefore is very incomplete—indeed it is plain that the draughtsman of the report has not aimed at completeness in this sense. He has rather singled out the issues which he considers most important and has given them prominence by passing over the rest. The adoption of this course was, we think, judicious and if we were disposed to criticise the report at all in relation to this matter we should be more inclined to observe upon the examples which the report exhibits of side issues treated inadequately than upon the instances in which the reader looks in vain for any utterance upon these subordinate points. For example, there is a very infelicitous paragraph (numbered 571) in which, passing from the three "Endowed Hospitals" to the remaining eight general hospitals with schools the Committee say of these latter that they "depend entirely for their support upon voluntary contributions, excepting in a few cases where they possess some small endowment." This exceedingly inexact reference to the financial condition of the "unendowed" general hospitals is the more remarkable because the earlier part of the report itself contains detailed references to the same matter and states, for example, that the London Hospital has invested property to the amount of £283,000 and St. George's Hospital to the amount of £441,000. The mistake is evidently due to haste and is by no means the only sign of haste in the preparation of the report. It is well that this should be pointed out, for strongly as in the main we agree in the conclusions at which the Committee has arrived, we cannot but perceive that on many points its utterances will form a starting-point rather than an end of discussion.

The main result of the Lords' deliberations is embodied in the suggestions which they have put forward with regard to the formation of a Board of Supervision. The constitution which they approve is that of an elective body consisting of forty-nine members, to which the various hospitals and other bodies concerned will send representatives. It is proposed that for this purpose the hospitals shall be grouped and that to a group of small hospitals shall be 'conceded a

representation equal to that enjoyed by one large institution.—The other constituent bodies are to be the dispensaries—in two groups,—the various medical and surgical professional authorities of the metropolis, the London County Council and the Sunday and Saturday Funds. The duties of the Board so constituted are roughly sketched and amount to a system of watching and recording the operations of the various institutions committed to its jurisdiction. It is to receive annual reports and statements of accounts, to examine and report upon proposals for new hospitals, to maintain a system of visitation and to "turn its attention to the possibility of so organising medical charities as to secure their coöperation with one another and the coöperation of medical charity with general charity." This is a result of great practical importance and equal promise of useful consequence. We trust that in some way it will shortly be realised. How this is to be done does not at all appear from the report and this singular omission is another of those signs of haste in its preparation to which we have previously referred. Probably, however—indeed, undoubtedly,—the idea in the mind of the Committee was that the Board would be created by an Act of Parliament and endowed thereby with all necessary authority for the exercise of its functions. It seems, however, probable that this part of the scheme has not been fully worked out and we think that probably some difficulty would be found in persuading the Legislature to move exactly on the lines sketched out by the Committee. The consultative authority and duty of observation with which it is proposed to invest the new Board are not unlike those which are confided to the Lunacy Commissioners or the Prison Commissioners in other spheres, and no doubt precedents could be found in other directions equally in point. Still the composition, so far as we know, of all these commissions or boards is very different from that suggested for the proposed hospital board. A body so popular in organisation, so large numerically and representative, so strong, could hardly be expected to confine itself in practice to the judicial function of criticism and the routine of receiving and compiling reports. Our feeling is that mischief would be sure to come of putting so powerful a machine to work upon so delicate a task. We think that in circumscribing the task the Lords' Committee has acted with great wisdom, but that for undertaking that task a much more suitable agent could be found and that two excellent schemes would be prejudiced by the failure of one ill-devised organisation, if a task requiring minute and painstaking attention to details and involving little or no exercise of control were confided to the hands of a large and popular assembly ill-fitted to carry on a laborious routine, but eminently adapted to exercise a large authority.

NEXT to the poor, for whom the hospitals are primarily intended, there is no body of persons for whom the recommendations of the Select Committee of the House of Lords on the subject of Metropolitan Hospitals have more immediate interest than the members of the medical profession. They are interested in them in two or three ways—in the efficiency and readiness with which they meet the cases of urgent medical need which in the first instance generally come under the notice of the general practitioner; in such a careful use of hospitals and their accommodation that they shall not pauperise those receiving their help, or enter

unduly and unfairly into competition with the hardworking general practitioner on whose ubiquitous presence by night and day the public, and especially the poor, depend for help in time of trouble. Further, the medical profession cannot fail to regard hospitals with interest as the chief centres of medical education from which medical light and learning emanate. We have dealt above with the report as far as it deals with what we may call the administrative and business aspects of hospital management. We propose now to consider rather two or three questions of special interest from the point of view of the medical profession.

The judgment of the Committee is, on the whole, highly favourable to hospitals and their management. The outspokenness and independence of the Committee are noticeable throughout, but chiefly in their somewhat severe criticism of the endowed hospitals and particularly in their allusions to the sanitary defects of St. Bartholomew's Hospital. They object to the old theory which allows the treasurer of such hospitals to do pretty much as he likes and strongly urge that they, as other institutions, should be governed by a board of managers and subcommittees. For the large general hospitals and particularly the London Hospital they have scarcely any words but those of praise. The charges against the London Hospital they regard as not substantiated by evidence. The difficulties that did arise they consider would have been avoided if the governing board had kept authority in its own hands and not delegated so much to salaried officers.

One of the subjects on which the medical profession feels strongly is the evil of the multiplication of Special Hospitals. The members of the Committee do not see their way clear to condemn all specialisation. They would except children's hospitals, ophthalmic hospitals and the Lock Hospital—on the latter subject, by the way, they express an important opinion that the authorities should have the power of detaining lock patients as "infected" patients who might wish, as such patients are apt to do while infected, to carry on their vile trade. But the Committee fully points out the proved evil of small special hospitals and deprecates their further multiplication. The deliverance of the Committee on the subject of Out-Patients will be regarded by many as the least satisfactory part of the Report. The Committee has patiently heard all its opponents have to say as to the abuse of this department and all its advocates have to say in its defence as a means of education, as a refuge to the poor "night and day." And it has on the whole adopted the views of its defenders and found it indispensable to medical education. The Committee goes further and expresses the opinion that the charities are not abused to any serious or appreciable extent and that the patients are not treated carelessly or by students instead of thoroughly qualified persons. This deliverance will not close the mouth of objectors to the present scale of the out-patient department. But it clears the ground for further discussion, especially in one way. It shows that the out-patient department is not only tolerated but cultivated, not so much for the sake of the poor as for purposes of medical education. Hospital practice in the serious sense of it is felt not to be sufficient to teach general practice and so all and sundry are welcome to the out-patient department for the sake of the pupils that have to be taught. With this great motive for its cultivation much vigilance is

not to be expected and there seems no hope of much limit being set to its growth. We cannot admit the force of the excuse. There are other ways of teaching students familiarity with common diseases under conditions that will not demoralise patients or injure general practitioners. As the Committee itself points out, there are the Poor-law infirmaries in which it would scarcely be too much to say that certain great groups of disease have recently been discovered. There is besides the great field of general practice itself, which under proper conditions can be largely utilised for purposes of medical instruction. We deny that anything like the present scale of the out-patient department is necessary for the purposes of the poor and we heartily agree with the Committee in throwing on the authorities of each hospital the responsibility for arrangements that shall prevent abuse. The out-patient is to some extent an unsatisfactory item in hospital charity and withal a mysterious one. He cannot be traced. The cost of him to the hospital cannot be ascertained. The members of the Committee, however, do not think the mystery impenetrable and we hope it will be still further elucidated.

The Committee makes a wise observation on the effect of the Metropolitan Poor-law Act of 1867 in altering the relation of the poor to the hospitals and everything relating to medical charity. They think further infirmary accommodation is necessary so as to enable the infirmaries to take the sick who are nursed almost entirely by pauper nurses out of the workhouse. They do not express any recommendation in favour of enlarging the staff of the workhouse infirmaries, or of introducing an outside or consultative element.

The Committee has found time to express an opinion in favour of the removal of all territorial restrictions of qualifications for appointments to London hospitals, singling out St. Mary's Hospital as the only hospital without such restrictions. It thinks that practitioners who have "graduated" elsewhere should not be excluded. We presume that "graduation" is not here used in its limited sense. With the general principle we agree. We must now for the present leave this Report which is characterised by much good taste and judgment, though in some respects it appears to be, as we have already intimated, somewhat hastily drawn up. It will not diminish the responsibility of hospital authorities, but it will weaken the excuses of all those who can afford to help hospitals and do not.

THE British sphere of influence is rapidly extending in Africa; in fact, it may be said that from the four cardinal points of the compass British influence, missionary enterprise and commercial undertakings are penetrating towards the centre of the continent. In looking back, let us say, to the time of the Niger expedition, it becomes clear that, apart from physiographical difficulties, it has been fever which prevented the civilisation of Africa long ago. It is true that the configuration of the continent—its lack of bays and estuaries and its want of rivers navigable from the sea—has prevented that rapid exploration and development which might have been expected. During the last twenty years, however, rapid strides have been made, and we are at present perfectly familiar with the main geographical features of the whole of the continent, although of course there is much field still left for detailed exploration. This

knowledge has, however, only been attained through great loss of life or permanent injury to health, primarily, we believe, due to fever. Turning to missionary enterprise in Africa, we note that both on the east coast and on the west, as in the centre, the heroic labours of the missionaries are "cabinéd, cribbed, confined" by the same cause; and now that commerce is making rapid strides in the large areas of the African continent which have during the past few years come under the sphere of British influence, we find that it is fever which proves the great barrier to the extension of commercial enterprise. What of the future? If our commerce, if our missionary enterprise, if our efforts at introducing the blessings of civilisation into the country are to be successful, it will apparently, as in other parts of the world, only be attained after the sacrifice of innumerable lives and at a great expenditure of money.

We have recently received reports from various quarters throwing grave doubts on the received etiology and on the nature of African fever. Is the disease due to malaria? If so, is the malaria in Africa produced by the same, or approximately the same, causes by which it is produced elsewhere? This naturally involves the whole subject of the nature, cause, prophylaxis, and cure of malaria. Recent bacteriological research seems certainly to point to a micro-organism, a polymorphic hæmatozoon, being concerned in the production of malaria in most parts of the world. At any rate, the researches of LAVEBAN in France, of MARCHIAFAVA, CELLI, and CAMILLO GOLGI in Italy, of VANDYKE CARTER and HERR in INDIA, and COUNCILMAN and OSLER in America, all result in a common agreement that such is the case, and the examination of the blood of a few patients who have returned from various parts of Africa also points to the same hæmatozoon being at work in that continent. On the other hand, it will not do to ignore the fact that there are observers, and observers of no mean order, who in India, in America, and in Africa deny even that malaria exists as a disease *sui generis*, and who maintain that the phenomenon witnessed in, for instance, intermittent fever are due to either errors of personal hygiene or to the action of "chill." It is certainly difficult to reconcile these last opinions with the widespread ravages of malaria, which, as Dr. HERR holds, possess the unenviable position of killing more human beings than any other malady enumerated in the nomenclature of disease.

Having regard to the vital importance of the issue involved in this question, we have decided to institute a commission of inquiry into the subject of the so-called malarial fever in tropical Africa, and an appeal is issued to all medical men who are, or have been, at work in tropical Africa to give their testimony. This testimony must be strictly limited to African experience of fever, in order to elucidate how far the malarial fevers of Africa are either distinct or identical with such fevers in India and other parts of the globe. To make the inquiry more complete, a Special Commissioner is engaged in personal investigations on the subject in West Africa. The schedule of inquiry which has been issued has been compiled with great care and not only calls the observer's attention to the various important points in connexion with the inquiry, but is also arranged in such a manner as to entail upon the investigator the minimum of trouble. It is hoped that all who can aid in this inquiry will give their hearty coöperation, so that the

vast amount of isolated information which must exist may be examined and tabulated. It is intended in due course to publish the results of the inquiry as a report of THE LANCET Special Commission.

It would be needless repetition to refer here to the numerous points to which attention is drawn in the schedule, but it may be useful to allude in somewhat broad outlines to a few matters with regard to malaria, and especially to what we know of its character in tropical Africa. Most persons will probably allow that malaria is more or less a preventable disease, for we have only to bear in mind the change which has taken place in its production and incidence in the United Kingdom since the days of CROMWELL and CHARLES II. Drainage and cultivation have done their work, and the scourge has been almost completely banished from districts which were once its endemic home. Again, the presence of towns checks the disease—in the case of Chicago, for example, the rapid growth of which has banished malaria from the district, although it would appear that its place has been taken by enteric fever, or perhaps, as the Americans would say, by a hybrid disease, typho-malarial by name. It must not, however, be forgotten that some methods of cultivation may produce malaria where it has previously been non-existent, or may give an impulse to its production—a.g., the introduction of the cultivation of the sugar cane into the Mauritius, or, at any rate, the extension of its cultivation in that country, and perhaps, as suggested by DAVIDSON, the introduction of the coffee-leaf disease into the colony in cases of plants from Ceylon, produced an outbreak of malarial fever in a district where up till 1866 paroxysmal fevers had been practically unknown. To illustrate the second point we may refer to the impulse which is given to the production of malaria in the new irrigation districts in India.

To return, however, to tropical Africa and to the conditions which there obtain. The first point to notice is that, although Europeans suffer most severely from fever in tropical Africa, the natives are not exempt from the disease, and it is found that although when remaining in their own districts they are comparatively free from the scourge, yet when they are removed from their homes, either during war or when acting as carriers in exploring parties, they suffer considerably from fever and, indeed, show less power of throwing it off than the whites. It is also well worthy in this connexion to note that Africans, returning, say, from America to Africa, suffer as severely from fever as Europeans. In tropical Africa those conditions of climatology and of the configuration of the ground and altitude, as well as cultivation, which influence the incidence and epidemic spread of malaria in other parts of the world, are apparently identical. It is only perhaps when we come to consider the manifestations of the disease itself that we may be led through the accounts given by travellers and other observers to any dubiety at all as to the identity of African fevers with fevers in other regions. Upon the surface it seems perfectly clear that African fevers may be classified somewhat as follows—viz., an ordinary intermittent fever which, probably after receiving the malarial poison into the system, may be induced by either a wetting or a chill after severe perspiration, as was referred to by Dr. PARKE in THE LANCET of May 28th; again, a fever of a remittent type, lasting from

ten to fourteen days, most usually experienced on the coast and forming the "acclimatisation fever" of older observers; once more, a remittent fever, complicated by bilious symptoms of extreme gravity, the well-known bilious remittent of the west coast of Africa; but this is a type of fever which is met with under certain circumstances all over tropical Africa and is almost invariably due to an individual equation. We then come to the severe fever known more especially on the west coast of Africa, but it likewise occurs widely distributed—namely, the Blackwater fever, which, according to EASMON (and he is probably correct), is simply an ordinary fever complicated by hæmorrhage from the kidney and deserving of no distinctive name whatever. In cachectic patients, or in such as have been exhausted by prolonged marches and exposure, there is another form of fever which tends to the continuous type. As a rule, it seems that the well-marked quotidian, tertian and quartan fevers are not so distinctively met with in tropical Africa as elsewhere, but it is a question if this is really the case and if it is not a fact that closer observation by trained medical men would show that even in the supposed continuous fever, to which reference has just been made, one or other of the well-known types of ague may not, owing to reduplication or anticipating paroxysms, really represent one or other of the classical forms of the disease. From what has been said it will be seen that with the information we have at present at hand there is really insufficient evidence to justify the statement that African fever has an identity of its own.

It is to be hoped that THE LANCET Special Commission will throw considerable light both upon the personal care and hygiene which would serve in a given case to ward off fever, and upon prophylactic measures generally with regard to it. That personal care may do a great deal in preventing fever none will deny, and with regard to prophylaxis it is of extreme importance that more light should be obtained from Africa itself. We know how much drainage has done in other parts of the world, as also the choice of salubrious situations on which to erect stations. But it is too much to expect that general laws will ever be able to settle this matter, so much depends upon local conditions. It is said, and rightly, that the administration of quinine will act as a prophylactic measure, and a great deal of valuable information has been gathered on the subject in all parts of the world, but it is a question of grave importance whether it is advisable for men to habituate themselves to the use of this drug. In the experience of many it is found that, should a person who has been taking prophylactic doses of quinine for a considerable period be unfortunately struck down by fever, far larger doses are required to cut it short; and even in many cases the drug may be said to fail. It is also a matter worthy of grave consideration whether the large and continuous administration of quinine does not injuriously affect the nervous system and therefore it would appear that further research is necessary before we can definitely understand the advantages or disadvantages of the prolonged administration of a drug which is nevertheless admitted to be one of the most serviceable with which we are acquainted.

THE frequency and variety of the operations performed through wounds made in the abdominal wall justify a special consideration of the best means of obtaining a proper

healing of these wounds, especially as the firmness of an abdominal cicatrix plays so important a part in the result of an operation. In the case of an ordinary laparotomy wound the surgeon endeavours to obtain two special features in the cicatrix—in the first place, firmness, and next, the absence of adhesion between it and the subjacent viscus or viscera. To obtain the latter he must unite the cut peritoneum as closely and accurately as possible and so get a perfect linear scar in the serous membrane. To ensure a firm, unyielding scar it is important to unite all the divided tissues and not merely the cut peritoneum and skin. Then when primary union has occurred the recent cicatrix must be supported from without by strapping, a bandage or a belt, until it has become strong enough to resist the abdominal pressure. Two main forms of suture are employed: generally the suture is threaded on a needle at each end and each needle is made to transfix the abdominal wall from the serous coat through all the structures to the skin. The other method is by means of a series of buried sutures. The first is a fine continuous suture of the serous membrane, then a second is placed in the cut or separated muscle, and finally the skin is sutured. At the end of a long operation such a suture is tedious and it is absolutely necessary to have aseptic sutures. There is no doubt the suture obtained by the system of buried sutures is very excellent and this should impress surgeons with the importance of stitching the abdominal wound in such an even, regular manner that the entire cut surfaces are brought into exact apposition until their union is secured.

Another group of cases is made up of those in which a permanent opening into a mucous canal is obtained—such, for example, as in gastrotomy and colotomy. Here the main purpose is to obtain a firm, unyielding union between the given viscus and the abdominal wall. A common plan to follow is to unite the cut edge of the parietal peritoneum to the skin and in that way close the wound of the muscle &c. and then to unite the serous and muscular coat of the stomach or intestine to the peritoneum and skin only. The advantage of this plan is that it brings into close apposition two serous surfaces which very quickly unite and shut off the serous sac. The drawback to it is twofold: In the first place, it takes time and in the second place the union of the parietal peritoneum and skin is liable to yield and allow the viscus to slip back. A far simpler and better plan is to draw out the stomach or bowel and unite it to the skin only. This plan is extremely simple and expeditious and, best of all, it makes an exceedingly strong union of the viscus to the abdominal wall. The serous coat of the stomach or bowel unites very quickly and securely to the cut muscle and fascia and no fear need be entertained of evil effects from blood or other exudation from the wound finding its way into the peritoneal cavity or of slipping back of the bowel.

In a third group are the cases in which a hollow viscus, an abscess or a cyst, is opened and drained. In the case of a hollow viscus—e.g., the gall-bladder after cholecystotomy or the urinary bladder after supra-pubic lithotomy or exploration—closure of the wound in the viscus and abdominal wall is desired without diminution of the size of the viscus. This is most rapidly and surely obtained if the bladder is united to the deepest layers of the abdomina

wall only and not to the skin. The gall-bladder should be stitched to the peritoneum and transversalis fascia only, the urinary bladder to the transversalis fascia and deepest part of the rectus muscle only: The effect of this is to have a granulating wound superficial to the mucous membrane, between it and the skin, and this tends to fill up and consolidate very quickly, closing securely over the bladder wound; there is also the minimum of displacement of viscera. Where the older plan is pursued of uniting mucous membrane to skin there is greater displacement and the opposed mucous surfaces of the bladder have no tendency to unite and so the fistula is longer in closing. Where, however, it is an abscess wall or cyst that has to be drained, the object aimed at is quite different. The healing process must start from the bottom and extend upwards; it must close the cavity and not merely the wound into it. The abdominal incision must be the very last part to consolidate and it may have to remain open for many months. It is an advantage to have any bar to its premature closure and therefore in these cases it is best to unite the cyst or abscess wall to the skin—alone or in conjunction with the peritoneum—preferably to the skin only.

Too much attention cannot be paid to abdominal scars to prevent their subsequent yielding. When extreme, such a yielding and the consequent hernia are great sources of suffering and even of danger to the patient and the means of relieving the distress are very imperfect and unsatisfactory. It is a case where prevention is vastly better than so-called cure. Such are some of the main principles that must guide the surgeon in the suturing of abdominal wounds and their importance is such that we may repeat them in the form of aphorisms. The closure of a simple abdominal wound should be as perfect as possible; the serous surfaces should be accurately united and all the cut tissues between peritoneum and skin should be brought into apposition with precision and uniformity. The means by which this is to be done are of far less importance than the attainment of the end in view. Where a viscus has to be permanently fixed to a wound in the abdominal wall it should be sutured to the skin only. Where a hollow viscus is drained without permanent obliteration of its cavity, its wall should be sutured to the deepest part of the abdominal incision only. Where a pathological cavity is drained with the object of securing its obliteration its wall should be sutured to the skin.

THE subject of Extra-uterine Pregnancy or, as better named by Dr. ROBERT BARNES, "ectopic gestation," which is theoretically included in the field of obstetrics, but almost always demands the attention of the gynaecologist, has come very prominently before the profession lately on account of several observers relating their experiences before the Societies and by the production of books and articles dealing with this difficult subject. Closely allied to this is pelvic hæmatocele, which according to some authorities is due in about a fifth of all cases to rupture of tubal pregnancies. It is well therefore to consider some points especially important to general practitioners, because in many of the cases recorded the existence of pregnancy has not been recognised by the medical attendant. Perhaps from not bearing in mind the possibility of this disastrous accident he supposes that the woman is

suffering from some form of "pelvic congestion," or if he discovers a swelling he diagnoses "an obscure pelvic tumour" or a "limited peritonitis with effusion," and only when rupture of the distending sac takes place is the nature of the case suspected. This is a condition which requires to be carefully differentiated, so that if possible timely rational surgical treatment may be adopted. Formerly the view existed that after insemination the spermatozoa wended their way through the uterine cavity, up the Fallopian tube, to meet the descending ovum, and it was almost universally taught that the ovum might be fecundated in any part of its course and the impregnated ovum might take root and develop in the uterine cavity, as in ordinary cases, or in the tube where it passes through the uterine wall,—the so-called interstitial or tubo-uterine form—or in the free part of the tube—tubal pregnancy—or take root in the ovary, or even in the abdominal cavity itself. Modern investigation has thrown doubt on the existence of these two latter varieties and Mr. LAWSON TAIT, whose extensive experience entitles him to speak with authority, believes that all ectopic pregnancies might be classed as tubal pregnancies. As to the causation of ectopic pregnancies we know little. The late Dr. PARRY of Philadelphia, in his excellent treatise, showed that these anomalies are most frequent in women who have been sterile for a long time, but they may occur in the newly married or in the mother of a family. It has been suggested that attacks of desquamative salpingitis in which destruction of the ciliated epithelium takes place will account for the occurrence of tubal pregnancy. Mr. BLAND SUTTON, who has made this point a subject of prolonged investigation, thinks that this statement contains an element of truth, but considers that it does not hold good in all cases, so that the causal relation between salpingitis and tubal pregnancy requires further elucidation. The usual course of tubal pregnancies is that early rupture takes place as a rule and according to Mr. TAIT is not delayed beyond the twelfth week of gestation. Rupture of the sac may be intra-peritoneal, with escape of the foetus into the peritoneal cavity, or it may be the intra-ligamentous form, with escape of the products of conception into the space between the folds of the broad ligament, being extra-peritoneal in character. It is in the latter form almost always that cases of extra-uterine pregnancy reach an advanced term, for sometimes development goes on after such a rupture, and the foetus may ultimately lodge in the peritoneal cavity as the result of secondary rupture. There are many points connected with the physiological and pathological histories of these important cases which have been cleared up or are being made intelligible by the careful study of the parts which have been removed by abdominal section and also by the exhaustive post-mortem study of frozen sections made by Dr. BERRY HART and the late Mr. CARRER. An interesting case, elucidating the true history of so-called "abdominal pregnancy," was recently related by Mr. TAIT to the Obstetrical Society of London, in which the foetus, still retaining its amniotic covering, seemed to have developed to the full term in the peritoneal cavity. It was evident, however, that it had originally been a case of tubal pregnancy, and rupture of the Fallopian tube took place about the tenth week of gestation, development going on thereafter in the cavity of the peri-

toneum. Mr. TAIT considered that this case may be regarded as giving the true solution of all cases of this variety. The important thing for the majority of practitioners is to bear in mind the possibility of these anomalous pregnancies, and the advisability of diagnosing the condition. The symptoms vary according to the advance of gestation. The patient herself very often has no idea that she is pregnant, because in the majority of cases she has not been pregnant before, and usually the practitioner has not his suspicions aroused owing to the usual signs and symptoms of pregnancy being absent or obscure. Cases have been diagnosed of diseased tubes, which on examination after their removal have been found to be gravid; but as a rule it is only when rupture of the sac occurs at some period before the end of the third month that the symptoms point to the actual state of matters, and these symptoms are modified according to the seat and direction of the rupture. If rupture takes place between the folds of the broad ligament the symptoms are less severe than when the tubal pregnancy bursts into the peritoneal cavity. In the intra-peritoneal variety the symptoms are characteristic of internal hæmorrhage after complaint is made of "something giving way" and death may supervene in the course of a few hours. Such cases of rapid death have occasionally been attributed to poisoning, but the true cause was discovered on post-mortem examination. The treatment by abdominal section is the rational course in tubal gestation, and the condition has been recognised and so treated before rupture. If at the time of rupture the symptoms of hæmorrhage be quite distinct and the patient's life in imminent danger then the abdominal cavity must be opened, and the bleeding arrested as soon as possible. If the rupture takes place between the folds of the broad ligament, operative interference is not so urgent as the hæmorrhage is restricted, but at any time in the subsequent course of the case surgical interference may be necessary to save the patient.

THE next few weeks of high-wrought excitement in the British Islands will have their quietus in a general holiday—antecedent and consequent giving no confirmation to the "error"—"vulgar," as any stigmatised by Sir THOMAS BROWNE—that contemporary exceeds all preceding life in the unrelieved stress and strain, the worry, the nerve-wear, and the other adverse influences by which suffering is lengthened and longevity curtailed. Among the bright, incidental discussions in Dr. PYE-SMITH'S lectures on the "Etiology of Disease" may be instanced that in which he drove another nail into the coffin of the otiose fallacy that the "ugly rush" of modern life incurs a prevalence of neuroses of every kind, bringing in their train a susceptibility to organic disease and an intolerance of effective treatment unknown to less bustling generations. To that as to the other tasks imposed by his subject the lecturer was more than equal, and we have seen no attempt on the part of any *fin-de-siècle* pessimist to traverse the reasoning by which he relegates the fashionable induction to the limbo of "hereditary fudge." That the induction should not only have found acceptance, but should still be propagated, is quite in keeping with the tenacious vitality of error, proving as it does that the generation which received it in bequest and is

prepared to bequeath it in return—"enlarged" if not "revised"—is also open to the imputation brought by HALLAM and THACKERAY against the society of fifty years ago—that it does not read!

If there is one feature of modern civilisation more distinctive than another it is the economy of force effected by its inventions and innovations. It is indeed the triumph of the mechanical, in substitution for the personal, factor that the former minimises the forth-putting of the latter. Take one of the most familiar directions in which the individual is called upon to exert himself—that of travel or getting about from place to place. If ancient or mediæval records or the published experiences of "sixty years since" teach us anything, it is that a journey of any distance used to be a more or less serious undertaking, to be planned and prepared for days or weeks in advance, and sure to absorb the traveller's mind during every hour of his progress till he found himself safe and sound, weary but thankful, at his destination.

Come quel, che con lena affannata  
Uscito fuor del pelago alla riva  
Si volge all'acqua perigliosa, e guata!

Dangers due not merely to the mode of transit, though these were real enough, but to the quality of the resting-places *en route*, to say nothing of the "gentlemen of the road" whose blackmail exhausted what the "perfidus caupo" had spared, kept the mind preoccupied morning, noon, and night, to the exclusion of that enjoyment shared by every present-day traveller; for whom vicarious exertion or agency minimises all hindrances to free attention, discursive or sustained. The reader has but to revert to SCOTT'S immortal picture of mediæval travel and hotel-entertainment in "ANNE OF GEIBURSTEIN," and to compare it with the comfort and convenience commanded in the same regions—the Switzerland and Germany of to-day—to realise the exemption from anxiety, privation and positive jeopardy secured him by nineteenth century arrangements for the economy of time, of trouble, of the thousand-and-one provocatives of worry and nerve-wear and neurotic susceptibility.

The certainty and punctuality of modern communication with the more distant latitudes is another phase of economy of nerve-force characteristic of contemporary civilisation. "The hope deferred that maketh the heart sick" was a frequent concomitant of the tardy, irregular, not seldom abortive postal system of classical antiquity and of mediæval times. What the anxiety and the disappointment of the expectant correspondent must have been in those worlds we know from the letters of CICERO and ERASMUS; indeed, we can realise it in the Italy of to-day where ill-advised retrenchments in the service induce an unpunctuality in despatch and delivery which goads the British man of business in his *villaggiatura* to something little short of madness. Till lately the whole continental life was fraught with these trials to mind and temper; proofs in point even now beset us and find ample illustration in their consequences. Take one of these illustrations out of many. It is notorious that the European countries which are most backward in civilisation and mechanical improvements are also those in which the soul-satisfying, soul-soothing enjoyment of nature in her picturesque or romantic phases is least in favour. But is not this because their inhabitants are so mentally preoccupied over the petty details of life—over the incidents of

a social arrangement the reverse of easy, those of transit included—that the undivided attention which is, even for the most sympathetic natures, indispensable to adequate appreciation of the beautiful or the sublime, is for those less sympathetic ones difficult, if not impossible? GASTON BOISSIER, it is true, expanding, if not actually borrowing FRIEDLÄNDER'S induction that the Latin races have not that sense of the lovely or the grand in scenery characteristic of the Teutonic, taxes the Romans with something like apathy to the sentiment of landscape. But in abatement of the charge he brings against those gifted pro-consuls and generals who found nothing but horror and repulsion in the Alpine passes which attract the modern nature-worshipper in thousands, may it not be pleaded that the hardships, the uncertainties, the positive dangers of travel in those days, must have deadened the most poetically-attuned minds to everything but a personal preoccupation, intelligible, if also ignoble?

Modern life may render it hard to be idle; but is not "brain rust" as prolific a parent of neuroses as "brain fag"? While every opportunity is now supplied for that wholesome exercise which all minds, in their infinite diversity, require, is there not also provided that not less wholesome recreation and transition which are equally necessary for normal evolution? The human organism has a self-adjusting, self-righting virtue that makes it intolerant of persistence in any course injurious to itself. It shifts its position, it leaves off in due season, it relieves or remedies itself with an instinctive punctuality that saves it from long-continued error. Every year multiplies its opportunities of restorative change: the railway, the steamship, the agencies to which fashionable theory attributes all the vague influences believed to impair the nervous system are precisely those which are most instrumental in bringing the requisite relief and renovation. Climate, thanks to these agencies, is now a therapeutic resource in yearly greater request, particularly for invalids drawn from those classes whose cerebral and moral powers are brought most intensely into play. The seaboard, the island, the mountain, high latitudes and low latitudes, the arctic yachting cruise, the sojourn in the winter city or in the great sun-bath of the Sahara itself—are additions to the consultant's armoury made available by those latter-day inventions which are superficially credited with the evils they most contribute to neutralise. Dr. PYE-SMITH has already laid medicine and rational therapeutics under many obligations. He has done few more opportune services than by demonstrating—with an acuteness and a command of scholarship in his case hereditary—that the means by which modern life is assisted and expedited stand in no causal relation to the genesis—real or supposed—of neurotic temperaments or of "nervous disorders."

WE are glad to be able to state that Mr. Gladstone has not suffered any serious consequences from the regrettable outrage of which he was the subject on Saturday last at Chester. Undoubtedly he must have endured great pain from the nature of the injury and the results at his age might have been exceedingly serious. Fortunately it has been otherwise.]

## Annotations.

"No quid nimis."

### MEDICAL CANDIDATES BEFORE THE CONSTITUENCIES.

IN greater force than hitherto the medical profession has come forward for parliamentary honours in the election now imminent. Constituencies of every kind—county, borough and great city—have medical candidates before them and each nationality, that of England, Scotland and Ireland, has its representatives among these. This, we cannot but think, is a wholesome innovation on the too reserved attitude maintained by the profession towards politics in days gone by. If returned, as there is reason to expect the majority of such candidates will be, the interests of the public in Parliament will be considered and safeguarded by them in a direction heretofore unrealised. Problems of the deepest importance will no longer be left to the half-informed, half-hearted initiative or promotion of the political amateur, and State medicine and professional education, in their manifold aspects, will for the first time have something like justice done them by those best qualified to take them in hand. A glance at the names of the medical candidates in nomination will reassure the profession and the public that, whatever may be thought of them as political partisans, they have the education, the experience and the ability to give to the problems referred to the attention they demand. Sir B. W. Foster solicits re-election for the Ilkeston Division of Derbyshire and grounds his claim to the honour on a record of good work already done. In the Walton Division (Liverpool) Dr. B. W. Richardson is a candidate and, if successful, may be counted on as an accomplished, eminently capable and fearless advocate of reform in sanitary and social questions. Dr. Charles Cameron, who stands for the College Division of Glasgow, is well known as a conscientious and useful member, never absent from his place when the interests of the public health or the adequate recognition of the profession are before the House; while Dr. R. Farquharson and Dr. G. B. Clark, the latter a candidate for Caithness-shire, the former for West Aberdeenshire, are honourable types of the medical legislator, prepared to add to their previous record of good service for the body politic. Ireland sends up for re-election a proportionately greater number of medical candidates than either of the sister kingdoms and in Mr. J. G. Fitzgerald, Mr. J. E. Kenny, Dr. Tanner and Mr. J. F. Fox has already found popular representatives with their constituencies and their colleagues. Other names in the list of candidates are those of Dr. E. C. Thompson, who contests Mid-Tyrone; Dr. Verdon, who stands for the suburban constituency of Norwood; and Dr. Pollard, who courts the suffrages of the Southport Division of Lancashire. The number may yet be reinforced by hitherto unannounced candidates who, at the eleventh hour, have come forward for constituencies not yet contested. But, even as it stands, the list we have set forth is more numerous than any previous general election has called forth and the character of its *personnel* is not inferior to that of any equal number of men drawn from other walks of life. Parliamentary representation, discussion and legislation have nothing but good to reap from such an accession of the working power of members professionally educated like these.

### CHOLERA AND ITS PROSPECTS.

ALTHOUGH cholera is decreasing at Meshed, the fatal attacks having fallen to some thirty-five a day, yet the disease has extended over a wider area and has at last entered Russian territory in Europe. Passing in a westward direction from Meshed, a number of towns have at intervals

been attacked in the direction of Astrabad and still further westward the disease subsequently appeared at Abasabad on the southern shore of the Caspian Sea. But the disease also crossed the mountain frontier between Meshed and Russian Turkestan, making its appearance notably at Khnaka and Askabad. Then it followed the railway route and has since been reported at Usun-ada on the eastern shore of the Caspian. The passage across the Caspian from this point is not difficult to understand and as a matter of fact the important port of Baku in European Russia, situated on the western coast of the Caspian, soon became attacked. Thus the southern portion of the Caspian Sea has been invaded at three points, and not only so, but the disease would appear to have extended in a south-westerly direction from Baku towards the Turkish frontier, for the town of Shusha, in the province of Elizabetopol, is now also a seat of cholera. There is, further, the prevalence of cholera in Samarkand and Bokhara, in both of which Russo-Asiatic states a number of towns have been attacked, and between which and Russia in Europe there is a not unimportant traffic. No trustworthy statistics are as yet available as to attacks or fatality, but it is certain that in Russian territory there have been several hundred deaths from cholera. The town of Bokhara is said to have escaped and its escape is attributed to the advanced sanitary measures which have been steadily adopted there since last December, the action having been taken at the instigation of the resident Russian diplomatic agent. The immediate interest in this intelligence lies, for us, in the prospect of a European invasion of cholera. The route which the disease has taken is by no means a fresh one; and it is, besides, one that by reason of its traditions as to Oriental plague in and about Astrakan is known to be one where the conditions favourable to the diffusion of cholera have long since abounded and still abound. It is, at the present moment, impossible to forecast the future. But without professing to any prophetic accuracy, we may say that there are substantial reasons for fearing that eastern Europe is in risk of cholera invasion. At the same time we may add that, unless the extension becomes more rapid than it has been during the last month, an even greater danger to Europe may lie in a recrudescence of the infection next year than any wide prevalence this year. If this apprehension be correct, time will be afforded to Governments and sanitary authorities to prepare themselves in advance by means of those well-known sanitary measures which constitute the best defence against cholera invasion.

#### FATAL RESULT OF WATER DRINKING.

AN old way of poisoning criminals used to be to compel them to swallow large quantities of bull's blood and it is interesting to note how this acted as a means of causing death. Bull's blood is not a poison at all in the ordinary sense of the word, but when it enters the stomach it forms a coagulum, and instead of the organ being filled with liquid which might be ejected by vomiting, it is filled with a solid mass. This mass presses upwards upon the heart and displaces it. The pressure upwards upon the lungs interferes with the respiration and the pressure backwards upon the aorta, vena cava and the solar plexus would probably be sufficient to cause death. The same thing occurs in animals when they are first turned out among the clover; they overeat themselves and are very likely to die from over-distension. A case was recently reported in the newspapers of an Irishman who had eaten largely of potatoes and milk and who died suddenly. The post-mortem examination revealed no disease. He was apparently healthy, except that his stomach was distended, and no doubt he died in exactly the same way as the criminals who were compelled to drink bull's blood. Generally death cannot be brought about by the simple drinking of fluids, because the stomach

is able to eject them. Apparently, however, this is not always the case. In one of the lay papers a few days ago there was a notice of three Frenchmen who laid a wager as to who would drink most water and all three of them died in a comparatively short time. The death in this case might have been partly due to the distension of the stomach and partly to the effect of the water on the blood after its absorption. It very rarely happens in a healthy person that enough water can be absorbed to cause any alteration in the blood, because it is excreted as rapidly as it is absorbed and the composition of the blood is kept nearly constant. Death from the action of water on the blood may occur after profuse hæmorrhage when thirst is extremely urgent. This has been noticed in the battlefield and also in the case of women who have been nearly drained of blood by hæmorrhage. In these cases it is always advisable not to give pure water to quench the thirst, for it is not only an irritant to living tissue, but it is also destructive to the blood. The risk of injury is considerably lessened by adding a little salt to the water, making it of the strength of the physiological normal saline solution.

#### THE PERFORMANCE OF CLASSIC PLAYS AT PUBLIC SCHOOLS.

THE "struggle for existence" on the part of the ancient languages amid the competing claims of the "modern side" has forced their teachers to introduce salutary innovations on the traditional methods of cultivating them. One of these innovations, which has gone far to restore their popularity, is the performance at school or college of the masterpieces of Greek or Roman dramatic genius, and year by year the practice has commended itself with steadily increasing advantage to teacher and pupil. Like many other so-called innovations, this one is simply an extension of old custom, a connecting link with which may be found in the "Westminster Play." At the Renaissance and for two or three generations after it, not only were classical plays performed by the young scholars at the principal seats of learning, but now plays—mostly in Latin—were specially written for them and reproduced on the academic boards under the superintendence of the teaching staff. George Buchanan, to instance no other, was one of the most successful of these playwrights; and for the students at the College of Bordeaux, in which he was the leading Latinist, he wrote the "Baptistes" and the "Jephthes," the plot of which he derived from two of the most tragic incidents in Old and New Testament history. With a similar object he translated into Latin verse the "Medea" and the "Alcestis" of Euripides. His pupil Montaigne has put upon record how much he owed to these performances; but the benefits to be drawn from such modes of schooling the young mind in literature and language are not æsthetic or linguistic merely. The physical exercise they necessitate, the training of the voice, the development of the chest, the sway of the person are all most salutary adjuncts to the educational system, and indeed are but another revival of ancient practice in one of its most admirable phases. In their worship of the body (which no doubt they pushed to extravagant lengths) the "clara lectio" of the Romans was one of their most prized auxiliaries to the maintenance of health and the perfecting of the physical organism—a "reading aloud," as the late Dr. King Chambers pointed out, not in the constrained attitude and the grotesque mannerism of the candidate for "clergyman's sore-throat," but with head held back and chest thrown out, with distended nostril and animated eye, with sympathetic action and speaking gesture, as we see in gongs and similar relics of the plastic genius of antiquity. When, furthermore, such wholesome and life-invigorating exercise is carried on, as in ancient Rome or Athens, in the open air, we have all the conditions of a salutary gymnastic, coming in reinforcement of the physical training which is

now seen to be an indispensable adjunct of the growing boy's upbringing. The highest point to which such a happy resuscitation of classic method has yet attained is the performance of Greek or Roman plays as now practised at some of our chief public schools and Universities—at none more effectively than at Bradfield College where for three days last week might have been witnessed the "Agamemnon" of Æschylus, mounted and acted with a success that profoundly impressed the beholder. The theatre occupies a chalk pit within easy distance of the college, its steps rising in terraces for the accommodation of the audience, as may be seen in such comparatively perfect examples of the ancient open air theatre as that at Fiesole. The head master, Dr. Gray, drew happily on his archaeological lore for the scenic details so as wellnigh to persuade the auditory that they were really assisting at an antique performance. Careful rehearsal had obviously prepared the young actors for their more than adequate representation of the *dramatis personæ*, Mr. Willis evoking just admiration for his "Cassandra" and the head master himself winning universal applause for his rendering of the short speeches assigned to the Coryphæus. To the young men who witnessed—still more to the young men who acted—the play, a deeper, fuller appreciation of its grand and subtle beauties than was possible under the old reading-lesson system must have been imparted, so that in after life, in the intervals of professional or business cares, they must inevitably go back with pleasure to an original so vividly and agreeably imprinted on their minds. We hope to see the extension to all public schools of such performances as that for which Bradfield College has earned so honourable a reputation—performances not limited to Greek or Latin *œufs-d'œuvre*, but including the master works of Molière and Racine, of Goldoni and Alfieri, of Schiller and Shakespeare himself. It is surely a welcome revolution in the "wearisome bitterness," as Milton called it, of classical study at school, when mind and body, eye and ear, voice and gesture, are combined in the interpretation of its most interesting subject-matter in so effective and in every sense so salutary a mode as in the revived representation of Æschylus and Sophocles in the open air.

#### FOOD-SUPPLY AFLOAT.

"ENGLAND expects every man to do his duty." So ran Lord Nelson's famous signal at Trafalgar. Is it not time to put the converse of the saying, "Every man expects England to do hers"? Certainly she has been wanting, in many ways, to her sons of toil, agricultural, mechanical and combatant—to none more than to her "hearts of oak." The privations of her merchant and naval seamen are matters of history, burnt into her annals by writers like Smollett, whose picture of the horrors of the Cartagena expedition, in which he served as surgeon, forms one of the most tragic pages in literature. Scurvy down to much more recent times decimated her crews, in spite of the warning note of John Woodhall, surgeon's mate, in 1636, who suggested the lemon-juice ingredient in naval diet, which was made obligatory only in 1795 by the exertions of another medical philanthropist, Sir Gilbert Blane. The disease is now practically extinguished in the services afloat, so much so that naval surgeons assert they have never seen a case of it; but from time to time we have evidence that the neglect—or worse—with which the food-supply of seamen is maintained still justifies the indignation of the sanitary reformer. We need not go back to the shameful frauds practised on more than one Arctic exploring expedition in which the tinned meats and vegetables proved, when opened in high latitudes, to be unfit for consumption. Only the other day the good ship *Crofton Hall* is stated to have revealed as scandalous a breach of faith in the victualling of its

hands as any yet made known to us. Having sailed with a clean bill of health on the 3rd ult. from Calcutta, she put back to that port on the 13th with but five out of her crew of twenty-nine in a condition for active duty. And the alleged cause was that meat had been served out in so advanced a stage of decomposition that many of the sailors threw it overboard the first day. Notwithstanding this emphatic protest the tainted meat continued, it is said, to be set before them till, hunger surmounting disgust, the whole stock was consumed. By this time the inevitable consequences became apparent. "Cholera"—or at least violent diarrhoea—broke out on board, carrying off two men on the second day, four others later, and ere the week closed putting nearly all hands on the sick-list. Calcutta was shocked to see the vessel return in a state so appalling, and the indignation of the citizens may be imagined. Pending the official inquiry, we may remark that the case occurs not inopportunistly when questions of sanitary reform, among others, not more clamant, are coming before the constituencies. Protection for the lives and limbs of our sons of toil is rapidly asserting its truly imperial importance, and no attempt at its practical solution can be regarded as complete which fails to take cognisance of the victualling and health of our crews, combatant and non-combatant, in whatever waters they may serve.

#### SMALL-POX PROSPECTS.

ONE of the most serious prevalences of small-pox is that which is still in progress in and about Halifax, the borough itself and a number of surrounding sanitary districts being affected. Special arrangements have been made as to attendance on the sick and at least one hospital has been hurriedly erected in order to isolate the patients. Seventeen cases are also reported to be in the small-pox hospital at Liverpool. In the metropolis, the diminution in the number of fresh cases which set in some weeks since has, in accordance with our anticipations, been maintained; the number of fresh attacks during each of the four weeks ending June 18th having been thirty-one, twenty-eight, twenty and thirteen respectively. Thus, as we have already suggested, the main danger to be anticipated is the recurrence of the small-pox, which has managed to diffuse itself in a number of centres, during the approaching winter.

#### A WORD OF PROTEST RE TESTIMONIALS.

SEVERAL correspondents complain of being written to for testimonials by gentlemen with whom they are unacquainted and whose names are perhaps only known to them by the occasional receipt of a treatise or of a reprint of a paper read before a society or published in one of the periodicals. We must express sympathy with practitioners in their complaint, but should have thought that they usually consigned pamphlets, if apparently sent to them for such a purpose as obtaining a testimonial at some future time, to the waste-paper basket. We find, however, that many of the most eminent men in our profession and some of our busiest consultants carefully read and value them. At least this is the only conclusion at which we can arrive when we examine a batch of testimonials—over thirty in number—which have been given to, we believe, a very eligible candidate for an appointment at a hospital. In these testimonials one-third of the writers explicitly state that they have no *personal* knowledge of the candidate, and it is clear that, with two or three exceptions, the others are equally ignorant. From the following typical example the character and value of these testimonials may be estimated: "The writings of ..... show that he is a ..... who possesses a high degree of medical ability, scientific and practical, which cannot fail to ensure for him future distinction and to augment that which he has already

achieved." Many others go a little further and are bold enough to assert that if the candidate be elected it will be of marked advantage to the institution. Eminent members of our profession evidently therefore feel themselves justified in testifying to the possession of those practical qualities which are essential to an important hospital appointment by a candidate whom they have never seen at work. We question if they would not more carefully consider their position if they were asked to testify with regard to a post at their own respective hospitals. The manifest injustice to other candidates involved in the giving of such certificates of proficiency need not here be adverted to. We need only say that they would be valueless in the estimation of any judicious medical committee; and if submitted to a lay committee "the more 's the pity of it," as they might even turn the scale against the candidate in whose favour they are written. If good nature prompts kind hearts to yield to the temptation of giving testimonials to gentlemen of whom the givers have no personal knowledge, the latter can only blame themselves if their time is invaded by every applicant for an appointment who has had the opportunity or ability of writing an essay and who takes care that it has been sent to them and doubtless afterwards reminds them of the fact. The objectionable practice is one of their own creation and the remedy is in their own hands.

#### "CURES" FOR INEBRIETY.

A CIRCULAR has been widely distributed by another American company which also professes to cure this disease, but of course disclaiming the method to which we referred in a former number. From this we learn that a medical man with an English qualification is the medical officer to the company, and the same gentleman begs to state that he has answered our article of June 6th, 1892. The distribution of a small book of the usual type, affording only the vague information that the treatment is by hypodermic injections of modern alkaloid, is another instance of the total disregard of professional ethics in these matters to which we then referred. There is no question but that any medical practitioner is passing beyond the limits of professional etiquette in thus administering secret remedies, and we would suggest that the licensing authority from which he derives his qualification should take some notice of the circular and pamphlet. From an advertisement which appears in our columns it will be seen that Dr. Leslie E. Keeley has been invited to explain his treatment to the Society for the Study of Inebriety on July 5th. This is a proper method to pursue.

#### CRUELTY TO CHILDREN.

THE *Child's Guardian* for June contains a full report of the eighth annual meeting of the National Society for the Prevention of Cruelty to Children. We are pleased to learn from it that the needful work done by the Society continues to grow in public favour and effective usefulness. It is significant of the care with which the cases dealt with by the Society are selected that out of 8324, the total number brought before it during the past year, 7291 proved to be indictable on the ground of cruelty. We would, however, direct attention specially to certain points in the treatment of children and the detection of cruelty discussed by speakers at the recent meeting. Some observations by Mr. H. H. Fowler on the regulation of circus training in the case of children may be mentioned in illustration. Still more evidently called for was a vigorous protest by the same gentleman against the practice of child insurance. The object of life insurance, as he remarked, is to provide compensation for pecuniary loss sustained in consequence of a death. Where the deceased was a child no such loss was incurred and consequently there was no real occasion for insurance. Any difficulty as to fun expenses would best be met by some

arrangement which would provide, not a sum of money, but the services of an undertaker and other incidental necessities. The fact that cruelty, and gross cruelty too, is met with not only in poor but in wealthy homes was noticed by more than one speaker. It may be quoted here as affording a suggestive answer to some who attribute this form of crime, in the artisan class to pressure of poverty. The Earl of Fife did good service in advising that the powers entrusted to the police under the Cruelty to Children Act should be more freely used than they now are. Among those present at the meeting were the Bishop of Rochester, the Bishop of Portsmouth (who appeared for the Archbishop of Westminster), Lady O'Hagan, Mr. Benjamin Tillett and others whose names afford sufficient evidence of the scope of public interest in the Society and of the worthiness of its endeavours. A well-deserved reference to the strenuous labours of its secretary, Mr. Benjamin Waugh, should not be forgotten in this brief report of proceedings at its latest annual convocation.

#### STREET ACCIDENTS.

MR. GAREY, M.R.C.S., of Glasgow, who is a member of the Town Council of that city, is to be congratulated on having recently induced the Council to deal more liberally with members of the profession who are summoned to attend in cases of street accident. Hitherto the fee for such attendance as only been paid when the injured person was both able and willing to pay it, but in future the city will pay a fee of five shillings in all cases of day accidents and ten shillings in night accidents; and this will be done whether the doctor be summoned by a police officer or by any other person. This arrangement must be regarded as fairly liberal on the part of the City authorities, in view of the fact that already there are specially appointed casualty surgeons receiving amongst them £460 a year and that the new system is altogether supplementary. The position of casualty surgeon has been frequently held by surgeons who have become eminent. Dr. Wm. Macewen did some excellent work in this department in his earlier years. We feel sure the profession in Glasgow will fully appreciate Mr. Garey's action on their behalf.

#### ENTERIC FEVER AT NORTHALLERTON.

THE Northallerton Local Board of Health are very properly much exercised because of a prevalence of enteric fever in their town, and they have passed a resolution requesting the Local Government Board "to come and hold an inquiry into it." As a rule, when such resolutions are passed there is some obscurity attaching to the outbreak which calls for "inquiry." But nothing of the sort seems to exist in Northallerton. Mr. Lumley, the medical officer of health, indeed, tells his authority in advance what the result of the inquiry will be. He says "the wells on [one] side of the town would be condemned;" and he adds that he himself analysed samples from seventy-two wells some time ago and only found "three or four that were really good." The matter being put to the local board in homely phraseology, it was explained that the circumstances about the wells were such that "these wells are receiving the typhoid germs which fly like yeast in bread." We hardly understand, under these circumstances, what there is that has to be inquired into, and we should hold that the local authority were highly to blame for allowing such wells to exist were it not that some time since measures were taken to supply Northallerton with an improved water-service. According to the local press plenty of good spring water is available in or near the town and it should be obvious that it is action rather than inquiry that is wanted; the first action being to close the polluted wells and at once supply a wholesome water, at least twice a day to every house, by means of water-carts which have been filled

at a source where no risk of pollution exists. The remaining action, with regard to such matters as isolation, disinfection, &c., can be explained to the authority by their own medical officer of health and doubtless this has been already done.

#### THE CHELTENHAM LOCAL BOARD.

WE are pleased to find from the Cheltenham papers that the Local Government Board has removed the suspension of Mr. Walters, not, however, without a censure on Mr. Walters for ordering treatment without first visiting the case—which Mr. Walters denies having done. We still consider that the question of whether a Poor-law medical officer is justified in seeing a pauper patient without an order has not been satisfactorily settled by the central authority in its decision upon this case and we trust the matter will not be allowed to drop.

#### THE ASSOCIATION FOR THE ADVANCEMENT OF MEDICINE BY RESEARCH.

THE annual meeting of the Association was held on June 27th, Sir Andrew Clark presiding. The report showed the increasingly good work done by the Association and that through its instrumentality great facilities were afforded to those who were engaged in scientific work in obtaining licences. It therefore deserved the support of all who were interested in the advance of scientific medicine. The working annual expenses are but small, but as the funds are now nearly exhausted contributions are asked to enable the Association to continue its good work. These may be sent to the treasurer, Dr. Wilks, 72, Grosvenor-street, W., or to the secretary, Mr. Stephen Paget, 57, Wimpole-street, W.

#### THE ISLINGTON MEDICAL OFFICERSHIP OF HEALTH.

ON Friday of last week there seems to have been another vestry storm over the motion for suspending the by-law which would prevent Dr. Wynn Westcott, lately a member of the vestry and now temporary medical officer of health, from becoming a candidate for the permanent office. There were only eighty-five members in the division. Eventually the resolution to suspend the by-law was carried by fifty-seven to twenty-eight votes. It looks as if Dr. Westcott's friends were more in earnest than those who do not like to see by-laws tampered with in favour of ex-members of the vestry. There are, we understand, about thirty candidates. They will be sanguine gentlemen if, in the face of these proceedings of the vestry, they fail to see a foregone conclusion.

#### "CHOLERA NOSTRAS" IN PARIS.

The Consultative Council of Hygiene of France have held an important meeting to discuss the prevalence in Paris of cases qualified as "cholera nostras," but which have excited considerable alarm. An official report was drawn up and will shortly be published. From private sources we have received information on the subject, but before publishing the same will wait till the issue of the official report. We trust that this report will contain a full account of the bacteriological experiments made with the microbes derived from the dejections of the patients. The history of the cases should be coupled with some account of the water-supply in the districts that have most suffered. The epidemic, slight as it was, is supposed to be subsiding; it was nevertheless sufficiently serious to justify special measures on the part of the Paris Municipal Council. A committee was secretly appointed to inquire into the matter and to take special measures should the epidemic suddenly spread. A number of deaths continue to be registered under the heading of "Cholera nostra, Cholérine et Entérite," the latter term especially may mean anything. It will be found,

we believe, that many of these deaths are due to drinking the water of the Seine; or, in any case, that such deaths are more frequent in those quarters and outlying districts of Paris where the water companies only provide water from the river Seine. We trust that so independent and official a body as the Consultative Council of Hygiene of France will deal fearlessly with this question and that the short-sighted desire to prevent panics will not hinder the publication of the full truth.

#### PROFESSOR MURRI OF BOLOGNA.

FLORENCE, as we recently announced, has lost in Professor Federici one of her most brilliant and useful teachers and consultants, and her Senatus Academicus, consisting of the *personnel* of her Istituto di Studi Superiori, has been sounding Professor Murri of Bologna as to his willingness to accept the vacant post. At the prospect of seeing their own seat of learning deprived of an exceptionally able and effective colleague, the Bolognese professors have met in council and agreed to frame an address urging Professor Murri to let no inducement tempt him to prefer the Florentine chair to that in which he has won such honour for himself and for Bologna. So matters at present stand—the Bolognese students adding their voice to that of their professors for the retention among them of a teacher so difficult to replace. We believe no action on either side will be taken till the close of the month, when Professor Murri will have returned from Carlsbad.

#### THE ANNUAL GENERAL MEETING OF THE ASSOCIATION OF FELLOWS.

THE Association of Fellows of the Royal College of Surgeons of England held its annual meeting on Thursday at 5 P.M., at the rooms of the Zoological Society, 3, Hanover-square, Mr. Holmes, Vice-President, in the chair. Among those present were Mr. Alban Doran, Mr. John Tweedy, Mr. Allingham (sen.), Mr. G. F. Helm (Cornwall), Mr. Vincent Bell (Southampton), Mr. Geo. Jackson (Plymouth), Mr. T. B. Keetley, Mr. Purnell, Dr. Collins and others. After the confirmation of the minutes a long and interesting speech from Mr. Holmes and the adoption of the report of the Committee, a resolution was unanimously passed to support Mr. John Tweedy at the election on the 7th inst. About fifty letters, postcards, &c., had been received from members who regretted their inability to be present. As we are going to press we reserve further notice of the meeting till next week.

#### CORNISH SANITARY ADMINISTRATION.

THE County Council have stirred up the question of sanitary administration in Cornwall and they have done well, for sanitary activity has never been a leading characteristic of this remote member of the sanitary body of Great Britain. Some of the annual reports of the medical officers of health are regarded as inadequate; others, by way of contrast, are held to be typical of what such reports should be and that prepared by Mr. J. Q. Couch on the Madron urban district is quoted *in extenso* as a pattern. The precise function of County Councils towards annual reports of medical officers of health has always been very obscure; such useful action as they have commonly taken on them has been the result of advice by a county health officer. Whether such an official exists in Cornwall is not clear. We read in the local press of the "honorary medical officer" to the county, but he comes in for some reflection too, for he is told that the committee of the Council fear he has given a more encouraging report on the sanitary condition of St. Ives than the circumstances warrant. The whole story of the Council in this matter is really somewhat difficult to understand.

## FOREIGN UNIVERSITY INTELLIGENCE.

*Athens.*—Dr. R. Nicolaides has been promoted to an Extraordinary Professorship of Anatomy and Physiology.

*Basle.*—Dr. A. E. Burckhardt has been promoted to an Extraordinary Professorship of Hygiene.

*Bern.*—Dr. W. von Speyr has been promoted to an Extraordinary Professorship of Mental Diseases.

*Breslau.*—Dr. J. Kolaczek has been promoted to an Extraordinary Professorship of Surgery.

*Ghent.*—Dr. van Imschoot has been appointed to give the lectures on clinical surgery which have hitherto been given by Dr. F. Soupart, Emeritus Professor.

*Greifswald.*—Dr. A. Kruse has been recognised as *privat-docent* in General Pathology and Morbid Anatomy.

*Munich.*—Dr. Moritz has been appointed Extraordinary Professor of Medicine, with charge of the Policlinic in the Reisingerianum.

*Vienna.*—The following promotions to Extraordinary Professorships have been made:—Dr. Englisch, Surgery; Dr. Bergmeister, Ophthalmology; Dr. Hochsetter, Anatomy; Dr. Kolisko and Dr. Paltauf, Morbid Anatomy.

*Warsaw.*—The Medical Faculty has selected for the Lectureship on Surgical Pathology Dr. M. A. Vasalieff, chief Surgeon of St. Roch's Hospital, and for the Lectureship on General Pathology and Therapeutics, Dr. M. K. Zénets.

THE following invitation has been issued to the Fellows of the Royal College of Surgeons along with their voting papers:—"The President and Council invite the Fellows to meet them in the Theatre of the College on Thursday, July 7th, at five o'clock P.M., after the conclusion of the Election to the Council on that day."

DR. A. P. LUFF, lecturer on medical jurisprudence at, and physician to, St. Mary's Hospital, has been appointed Official Analyst to the Home Office, in the place of the late Dr. Meymott Tidy.

## REPORT OF

## The Lancet Sanitary Commission

ON THE

## WARMING AND VENTILATING OF PRIVATE DWELLINGS.

THE best practical application of the principle of warm walls and cold air is undoubtedly the house which M. Somesco, Civil Engineer, has built for himself at Creil. We were fortunate in visiting M. Somesco on a day when a strong north-easterly gale was blowing. Wind creates greater difficulties than cold; but on this occasion we had both wind and cold. It is important to note that M. Somesco's house is built on marsh land. On both sides of the house there is a river and but for the construction of embankments flood would constantly occur in this spot. It was necessary to dig six feet below the level of the cellar floor to find a foundation. As much masonry had to be placed under the house to form a foundation as would have sufficed to build it. The garden, in the midst of which the house stands, was also artificial. Nor is there any shelter from the winds. The house stands alone in the midst of what is now a garden, but which used to be a dismal swamp. The system of warming and of ventilation has therefore been tested under the most trying circumstances. In shape M. Somesco's house is square, measuring twelve metres. It has cellars, two floors and above these under the roof a large sort of hall which serves as a billiard-room. The hollowed walls are 55 centimetres thick. The external wall is 22 centimetres and the inner wall 11 centimetres, so that

there is an intervening space between the walls of 20 to 22 centimetres. These walls are made with porous bricks, but in the basement the walls are massive. The house is like one box inside another box with a space of four to five inches between the two boxes.

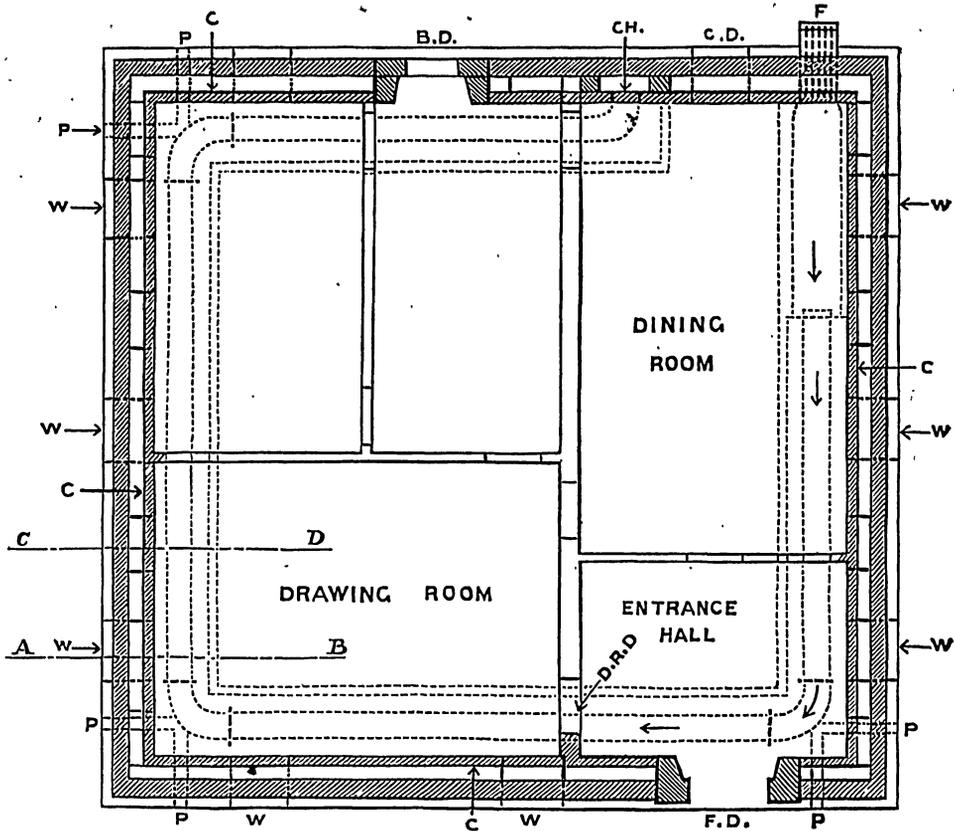

Outside, at the back of the house, there is an ordinary coal furnace. The smoke and heat from this furnace pass into a chamber built in the cellar of the house, measuring about six feet in length and not quite two feet square. From this heat chamber and going all round the outer walls of the cellar there is an enclosed passage. Suspended in the centre of this passage and also going the whole way round the house is a metallic flue of more than a foot diameter (35 centimetres internal and 37 centimetres external diameter). This serves as a chimney and draws off the smoke and the heat from the furnace and heat chamber, travelling horizontally round the four sides of the house; and then, when it is nearly back to the furnace, the flue opens into a chimney, the smoke and what heat remains go up vertically to the roof. In other words, the basement of the house is surrounded by a narrow closed passage, in the centre of which is suspended the flue or chimney from the furnace and this flue serves to warm the air in this passage. To keep the cellar cool and to retain the heat that goes round the cellar the wall of this passage is covered over with "sluck wool" or "silicate cotton," as it is sometimes called, which is considered a better non-conductor than asbestos. All round the house communicating with this hot-air passage there are inlets of fresh air from the garden, which measure eighty by fifty centimetres and are protected by metallic gauze or webbing. If the wind is very violent a coarse canvas may be hung in front of these air inlets on the windward side of the house. There are ten such inlets, the fresh air being delivered, as will be seen in the sectional drawing A B below the hot-air flue. The pipe or flue rests on iron bars and on a socket that permits the easy dilation and contraction of the iron with which it is made. The drawing C D shows how the air warmed in this passage ascends into the space between the two walls of the house. There are a number of these openings into the hollow of the wall all round the house.

The temperature in the hot-air passage varies from 114° to 122° F. This suffices to bring up the temperature of the inner wall on the ground floor from 86° to 92° F. The temperature of the inner wall decreases by about one degree centigrade per metre of height. Thus if the wall on the ground floor level is at 35° it will be 32°C. on the level of the first floor, which is three metres higher up. The hot air that travels up the hollow of the walls comes out in the large attic under the roof of the house. If this air is warmed to from 114° to 122° F. when it enters the space between the walls it will have fallen to about 104° F. as it emerges from the wall into the attic. From this attic the hot air filters into the open through the porosity of the roof and by the various openings, chinks, &c.

Much of the success of this experiment depends upon the porosity of the walls. Every precaution is taken not to interfere with this porosity. There is no plaster work put on the walls and there is no paint or paper. A light wooden frame is nailed on to the walls and from this tapestry—that is, a tissue, as far as possible a woollen tissue—is suspended and replaces paper. Some hangings of this description can be obtained that are hardly any dearer than good paper, and though for artistic purposes expensive woollens are employed, the expense in the long run is not great, for the cloth lasts an indefinite time and, unlike paper, can be taken down and cleaned. It also contributes very materially to maintain the warmth of the walls. M. Somesco has now lived in this house for some years. Without the aid of fires, when the windows were shut, he has never known the temperature of the rooms fall below 54° F. and this during the hardest frost. If the windows were thrown wide open the temperature indoors would not fall below 39° F. in spite of the frost. The air coming through the windows is absolutely cold and frosty, but the thermometer rises under the influence of the heat radiated from the walls. There is a fireplace in each room, though fires are very rarely lighted. When, however, it is very cold weather and the windows have been open for a long time, then it is expedient to light a fire for an hour or so. As there is no loss of heat through the coldness of the walls the room is warmed in a very short time. On the day of our visit the drawing-room windows had been open for two hours and as the weather was very cold a fire was lighted, but soon the fire was let out, the room was too warm, the thermometer marking 78° F. We left the drawing-room for some time. We opened the front door leading to the garden and the drawing

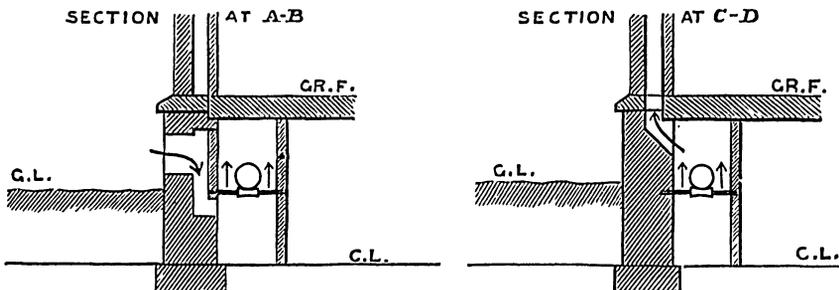

PLAN OF GROUND FLOOR AND BASEMENT OF M. SOMESCO'S HOUSE AT CREIL, OISE, FRANCE.

PLATE No. 1.

The dotted lines indicate the warming flue passing down the centre of the hot-air passage in the basement of the house. The plan gives the walls underneath the windows and indicates the space for hot air between the outer and inner wall. C C C, The hot-air space between the walls. C D, The door from the garden into the basement. B D, The back door. F D, The front door. D R D, The door from the entrance hall to the drawing-room. F, The furnace lit in the garden outside the house. The arrows from the furnace indicate how the smoke and hot air pass horizontally round the house till they reach C H, where a chimney carries the smoke vertically up to the roof. P P P P, Apertures through which brushes may be passed from the garden into the smoke flue to clean away the soot. w w w w, Position of the windows.

PLATE No. 2.

Section A-B, Showing inlet of air into the basement passage where the air is warmed. G. L., The ground level of the garden. c. L., The ground level of the basement or cellar. GR. F., The parlour floor or first floor of the house. The inlet of air as indicated by the arrows is below the smoke flue, which is suspended in the centre of the passage, so as to warm the air in this passage.—Section C-D, G. R., Shows the outlet of the air above the smoke flue. The air warmed by contact with this flue passes upwards in the intervening space between the inner and outer walls of the house, so as to warm the entire substance of the walls.

room door, which was from four to five feet from the front door. Thus the fresh air from the garden blew freely into the drawing-room. Yet, and though there was now no fire, the radiation of heat from the walls was such that the thermometer marked 66° F. In the garden the temperature was below 50° F. and a strong north-easterly gale was blowing. Thus we wore while indoors breathing cold, pure air from the garden.

We have seen that M. Somesco's house was built on a swamp; and yet the principal, if not the only, inconvenience from which he has suffered is extreme dryness. We visited other houses in the neighbourhood and found the walls stained by the damp to a height of six or seven feet; some of M. Somesco's furniture and other objects were spoiled because the wood had split in consequence of its extreme dryness. To counteract this inconvenience, M. Somesco has been obliged to place a large number of plants in different parts of the house, a measure which, however, adds considerably to the charm and beauty of the place.

The heat and dryness thus secured cost M. Somesco ten tons of English household coals per annum. His house has fourteen rooms and ten persons could live comfortably in it. The cost would then be one ton of coal per head per annum. But then it must be noticed that the furnace and the system of warming the passage round the basement of the house are somewhat roughly contrived and that more economical methods of obtaining the necessary heat could be easily devised. Then it must also be noted that it is not a question of warming one room or a portion of a room, but that the entire house is equally warmed, and warmed to such an extent that doors and windows are constantly opened and this in spite of the exceptionally cold and damp nature of the surrounding soil and the exposed position the house occupies.

Over and above all these considerations M. Somesco maintains he has realised the ideal that a dwelling should be like our clothes, only not portable, but permeable. It should be warm, because it should be made of materials that are bad conductors of heat. Indoors we should possess means of counteracting the chilling effect of the outer air. We ought to live indoors as we live out of doors and we should consider our house merely as if it were an extra great-coat. The coat, if porous, will be warm and healthy. One of the reasons, he says, why we are apt to feel uncomfortable when it rains is that the rain blocks up the porosity of the walls and that, too, on the windward side. As for microbes, M. Somesco proudly pointed to the artistic drapery which covered the bare bricks of his porous walls. "These are," he exclaimed, "my microbe traps. If I have any reason to believe that injurious microbes have been introduced into my house, I know pretty well where to find them. It would take but little time or trouble to unhook all this drapery, to put it in the disinfecting stove and there superheated steam under pressure, without injuring the cloth, would assuredly kill the microbes. Even without these artificial methods of purification, if the walls were porous, oxygen would go wherever the microbe went and nature would effect its own cure." How far a porous wall can filter and purify air, as earth filters and purifies sewage, is a matter which has not yet been investigated. He is of opinion that if we leave our walls alone and do not block them up with paint and paper we have for ordinary house walls in ordinary weather two cubic feet of air going through every square foot of wall in the course of an hour and this is probably enough to ensure the sufficient oxidation, if it goes on at all, of the materials of which the wall is made. Further, the porosity of the walls must also materially assist in the ventilation of the room which they surround. It was M. Somesco's delight to think that even when the doors and windows of his house were shut the pure air of his garden was blown upon him through the porous walls.

M. Somesco's house can of course only be taken as an experiment. The principles of which it is a practical application have not yet been adopted by the public. Already a private house is in the course of construction at Beauvais built on the same principles and they are also to be applied to the military hospital at Madrid. To sum up these new theories and methods, the teachings of M. Trélat, the practical experiments of M. Somesco, suggest that the natural porosity of our walls, especially the outer walls, should not be destroyed. These walls should be decorated, not with paper and paint, but with porous non-conducting substances, such as woollen drapery. The outer walls on the side nearest to the inner surface should be hollowed throughout, thus constituting a double wall with a space of about four inches between the two walls. A heating contrivance of

whatever description may be found most expedient or economical should be placed in the basement of the house. A warm air chamber or shaft travelling round the base of the outer walls should supply to the hollow in the walls air taken from the outside and warmed at the point of admission into the wall to a temperature of from 100° to 120° F. This should maintain the temperature of the inner wall at from 80° to 90° F. Then, he considers, the walls will radiate sufficient heat through the rooms to enable the inhabitants to constantly open the doors and windows and to breathe cold, fresh, outer air without inconvenience. As a rule fires will be unnecessary, dampness will be completely banished from the house, and to maintain some moisture in the air it would, he thinks, be expedient to decorate the house with numerous evergreen plants. The inhabitants should then be able to benefit by unlimited ventilation and could breathe pure, cold and fresh air coming upon them directly from the outside.

## THE LANCET

### Special Analytical Commission

ON

## ARSENICAL WALL-PAPERS.

---

SEVERAL authenticated cases of chronic arsenical poisoning by wall-papers as well as by such domestic articles as chintzes, cretonnes, table-cloths, lamp-shades, tapers, &c., are to be found in the columns of THE LANCET from the year 1860 to within a few years ago. Consequent on the publication of these cases the profession and the public have been vigorously warned again and again in our columns to exercise the utmost caution in the choice of a paper intended for decorative purposes and the attention of manufacturers has repeatedly been called to the fact that they were responsible in some measure for the mischievous and oftentimes alarming symptoms arising from the presence of arsenic employed in the preparation of the paper. Specimens of paper analysed in and about the years 1870 and 1880 were found to contain, in some instances, as much as from nineteen grains to forty-five grains, or even more, of arsenious acid to the square yard. It will be remembered that arsenic entered very definitely into the composition of certain colour compounds then only available for the purpose. Thus Scheele's green, which was at that time largely employed, is a definite compound of arsenic with copper known to chemists as copperarsenite  $\text{CuHAsO}_3$ . Schweinfurth green, again, or acetoarsenite of copper, is another example of a definite compound containing arsenic. Out of sixty papers analysed in 1877 only ten, as is recorded in THE LANCET, could be regarded as harmless in this respect; but in spite of many warnings impressed by precept and experience arsenical pigments continued to be used down to 1888 to 1889. Since this time, however, less has been heard of cases of chronic arsenical poisoning referable to this cause, although instances are forthcoming now and again. In the interest of public health we have been led, therefore, to reinvestigate this subject, to ascertain whether any improvement in the manufacture of papers has since been effected. As already pointed out, green papers have in past years most commonly contained arsenic, because with copper it forms the beautiful but dangerous pigment, Scheele's green. According to the results of a recent examination we have made, we found that in no case had this pigment been used; indeed we are inclined to the belief that the public may be fairly confident that papers of a green pattern generally contain no arsenic at all, as out of several samples examined no evidence of its presence was gained. Prejudice against a design in green rose high for reasons already cited and in the minds of many green is still the colour to avoid and the one most to be suspected. But on this very account alone manufacturers have studied this colour more than any other, with the idea of substituting for it a material equally effective and elegant, but free from any substance which could be regarded as injurious. This view is confirmed by the fact that excellent green pigments are now made without arsenic entering in any way into their composition. But, on the other hand, there may frequently

be traced small and variable quantities of arsenic in many of the dyes used in the staining process—as, for example, the anilines, for the manufacture of which arsenic is often employed. As a matter of fact, we have detected arsenic in minute quantity in lilac, marone and blue designs, probably not knowingly used, but nevertheless contained in the dye, which is doubtless bought by the paper-maker as a non-arsenical pigment. On this subject we have been furnished with some interesting information by Messrs. William Woollans and Co., who, as is well known, have for several years paid particular attention to the manufacture of absolutely non-arsenical papers. This firm assured us that although various manufacturers supply patterns guaranteed free from arsenic, yet on examination many of them are found to contain minute quantities of the poisonous metal. This is not wilfully introduced into the paper, but is contained in the dye, for the production of which arsenic is frequently employed. We have examined several papers so guaranteed and on the whole the results were fairly satisfactory. Where arsenic was found it was only in minute quantity, according to the exceedingly delicate test hereafter to be described. Other papers were obtained from the collections of various manufacturers bearing no guarantee at all, and arsenic in minute amount was invariably detected in these. Samples of papers were also secured, as varied in design and as elegant in pattern as the foregoing, but which were guaranteed to be coloured with *strictly* non-arsenical pigments. On examination such was actually found to be the case, no indication whatever of the presence of arsenic being afforded when the most searching test was applied. There is reason to believe that however intimately the steps, both in the process of the preparation of the paper and the colouring material, are known, it would not be strictly safe to guarantee them until the finished papers have passed this test. In fact, this is a precaution adopted by the firm already alluded to, who find that to be quite certain, although the paper is of their own manufacture, they must minutely and accurately test all those finished papers which are afterwards guaranteed to be absolutely non-arsenical. In the majority of instances of poisoning through the medium of wall-papers the quantity of arsenic found has generally been sufficient to establish with little doubt the *fons et origo mali*, but we do not think now—and we note it with considerable satisfaction, as THE LANCET in past years has not failed to condemn the use of arsenic in the pigment of wall-papers or to point out the dangers likely to arise from their use—that respectable manufacturers use arsenic at all, at least knowingly or willingly. Turning to the numerous analyses we have recently made, some papers were found to contain arsenic in varying minute quantity and others to contain absolutely none. The question therefore arises: Is the presence of arsenic, however slight the amount, to be tolerated at all? The test we have relied upon, and which is according to our experience the best and most delicate, is a modification of that known as Marsh's test. It consists in generating hydrogen from a mixture of perfectly pure sulphuric acid, water and zinc in contact with the suspected substance in a flask provided with a long funnel and delivery tube. The delivery tube is fitted with a drying tube containing calcium chloride and to this is attached the depositing tube, which is a glass tube six inches long and of one-eighth of an inch calibre. The purity of the materials having been ascertained by a blank experiment, a piece of the paper five inches square, cut up into small pieces, is introduced into the flask and a steady evolution of hydrogen gas is allowed to proceed until the whole apparatus is filled with gas. On now heating the depositing tube in the middle with a spirit lamp a metallic arsenical mirror varying in intensity as regards lustre and colour will be produced if arsenic is present.

Proceeding in this way with a score or so of samples and operating on five square inches of paper, deposits were obtained varying from a light, almost imperceptible brown to a blackish, but not opaque, lustrous stain. Now in experiments with a very weak standard solution of arsenious acid we were able to detect very readily  $\frac{1}{1000}$  of a grain of arsenious acid; and this amount, small though it be, gave a distinct black lustrous, though hardly opaque, deposit. Probably therefore not more and considerably less than  $\frac{1}{1000}$  of a grain of  $As_2O_3$  occurred in the quantity of paper experimented with above, as no more intense deposit than that yielded by this amount was in any single instance obtained. Is this quantity of arsenic in wall-paper likely to be injurious? One can hardly think so; but at any rate, if any doubt existed at all, and to be

quite positive (for there is no reason why the quantity of arsenic should not be subject to serious variation), wall-papers of excellent design can be secured which stand this test perfectly, and inasmuch as the delicacy of the test is such that  $\frac{1}{1000}$  of a grain even produces a distinct stain, such paper may be confidently regarded as absolutely non-arsenical. A paper yielding when tested under the conditions described above, a distinct black and lustrous deposit which is sufficient to cut off at any point a black line on a white ground, technically known as thick rule (eight to pica), would be condemned according to a rule fixed by many eminent authorities and perhaps on the whole it is a useful and justifiable standard. Very great care has to be exercised in carrying out this test, and on no account should it be performed until the absolute purity of the materials (zinc, acid and the glass of the apparatus) has been determined.

To sum up, one interpretation would appear to lend itself to the foregoing results. Owing doubtless to the action of the medical profession in unanimously condemning the practice of employing arsenical colours in wall-papers—an action in which THE LANCET took no small part—wall-papers loaded with arsenical pigment have apparently become a thing of the past, for amongst many specimens obtained by us from several respectable makers, those containing any arsenic at all contained it in almost imperceptible quantity, while others gave no response to a test which serves to detect the one fifty-thousandth part of a grain. Notwithstanding all this, it is necessary that a careful examination of wall-papers selected haphazard should from time to time be made in order that this satisfactory state of things may be maintained.

## DANGEROUS DIABETIC FLOURS.

IN order to ascertain by chemical analysis whether a flour is suitable for the use of diabetic patients a weighed quantity of the flour is taken and the carbo-hydrates converted into glucose by treating it with sulphuric acid in an inverted condenser for a few hours and then estimating the amount of glucose by the alkaline copper test. This process with care gives absolutely reliable evidence.

Some of the foods which have been advertised of late and especially American foods claiming to be "mainly free from starch," have, according to this test, been shown to be absolutely pernicious as diabetic foods. Our attention was directed to the fact that one specimen in particular which was advertised in the columns of THE LANCET had no claim whatever to the qualities ascribed to it, and we therefore submitted samples to analysis, and have ascertained that the so-called gluten flour contains over 66·60 per cent. of starch and the other, the so-called diabetic flour, over 62·00 per cent. of starch. That is to say, the quantity of glucose yielded on conversion or acid digestion is not a whit less than that similarly yielded by normal wheaten flour. The tests were performed again and again with varying amounts of flour, so that there cannot be the least doubt about the results.

One firm—that of Messrs. Farwell and Rhines—invited medical men to send for samples of these flours free of charge. The microscope showed them to contain wheat-flour granules in abundance. The preparations are made so as to simulate the appearance of gluten flour, for they are prepared in a fine granular form. A pamphlet is issued to the members of the medical profession and the preparations are even claimed to be recommended by the profession. Patients are under the impression that they are taking the proper diabetic food when in reality as bad a food for the disease as ordinary wheaten bread is being consumed. We have evidence before us of many instances of positive harm arising endangering the life and health of diabetic patients to an enormous extent. The effect of such foods is that patients who ought to have had little or no sugar in their urine according to the regimen adopted when under treatment have had large amounts of sugar accompanied by severe and marked symptoms of the disease. They have asserted that they have been taking the restricted diet, which has been absolutely contradicted by the state of the urine and their symptoms, and upon inquiry and investigation it has been found that they have been making use of the American flour under the

impression that it consisted of the proper gluten flour as supplied by the approved gluten food makers in London.

Whatever view of the nature of diabetes is held—and there is by no means unanimity on the point,—there can be no question at all as to the desirability of reducing the amount of carbohydrate food in the diabetic to the fullest possible extent. The doctrine, for instance, of faulty action of the liver, that of hyperglycogenesis and the like, is necessarily bound up with the amount of glycogen-forming material that finds its way into the portal circulation. Or if, as Dr. Pavy holds, the essence of the disease is due to defective assimilation of the carbo-hydrate element of food, the argument for restriction of diet is even more obvious. For on this doctrine the carbo-hydrate principles of food, instead of passing in their proper direction towards utilisation or consumption and disappearance in the system, in diabetes, through defect of their chemical transformation, simply run—through the influence of ferments with which they come in contact—into sugar, which, reaching the general circulation, will pass off by osmosis into the urine. It does not signify in the slightest degree what carbo-hydrate is given, the result will be the same. In giving carbo-hydrate food in this disease, not only is the food perfectly useless to the patient because it cannot be properly assimilated, but it produces an absolutely pernicious effect by reaching the general circulation and inducing at once an abnormal condition. In diabetes the blood in the general circulation contains sugar quite in proportion to the amount of the carbo-hydrate which has been ingested with the food and as the food of the general circulation becomes charged with sugar, so in proportion will be the deviation from the normal state, and in proportion to the deviation from the natural state of the food, so will be the failure in health and the symptoms of the disease. Of course this is true only up to a certain point, for under some conditions the dietetic restrictions are neither well borne nor efficient, and the physician may feel compelled to remove them in the interest of his patient; but such cases are exceptional.

#### THE REPORT OF THE PROCEEDINGS OF THE ASSOCIATION OF FELLOWS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

“A FURTHER ACCOUNT of the Proceedings of the Association of Fellows of the Royal College of Surgeons of England from March, 1890, to June, 1892,” has, as we stated last week, been issued and sent to the Fellows of the College. During the period specified the Committee of the Association has been actively engaged in carrying out the policy approved by the Association for advancing the interests of the Fellows of the College. “The Committee has held twelve meetings, there have been three general meetings of the Association, eight or nine meetings of subcommittees appointed for various purposes, and a deputation from the Association has held a conference with a committee of the Council of the College of Surgeons with very satisfactory results.” The main efforts of the Committee have been concentrated on endeavouring to secure for the Fellows the privilege of meeting within the walls of the College and of being convened separately from the Members to deliberate upon the affairs of the College. The proposals of the Committee expressed through a deputation were at first met with the statement that the solicitor of the College had given it as his opinion that under the existing charters this course of action would be illegal, but in the end the Council of the College submitted the matter to the Attorney-General and Mr. John R. Paget. The opinion given, which was dated Dec. 22nd, 1890, did not sustain that of the solicitor of the College, the first sentence affirming that “no legal objection exists which prevents the Council of the College granting the use of the College premises to either the Fellows or the Members for a meeting for purely consultative purposes.” “In view,” however, “of the pending litigation before Mr. Justice Stirling,” it was considered unwise “to permit a meeting of any section of the College except in the cases expressly provided by the Charter and By-laws.” In accordance with this opinion, the Council of the College resolved not to “take any action in reference to separate meetings of Fellows until the decision of the action Steele

v. Savory.” More than a year elapsed before the action was settled in favour of the defendants and soon afterwards the Council appointed a committee to consider what further advantages could be extended to the Fellows. The report of the Committee, which was adopted by the Council, recommended that meetings of Fellows apart from the Members should be held when the Council deemed it desirable, with or without a requisition from the Fellows and the Fellows have now been invited to meet the Council at 5 P.M. on the day of the ensuing election on July 7th. This result is in large part due to the Committee of the Association of Fellows. On more than one occasion it has been necessary for the Committee to formulate and to bring forward at general meetings resolutions expressing regret that the Council of the College had not consulted the Fellows before taking action, as, for instance, in regard to the scheme for the reconstitution of the University of London and the scheme for the fulfilment of the five years' curriculum. The proposals of the Committee of the Association for simplifying and improving the method of distribution and reception of voting papers resulted, as opinion was equally divided in the Council of the College, in the appointment of a committee to consider the existing rules. The necessity for altering and amending the by-laws, in order to effect the object in view, turned the scale against the proposals, but probably at no distant date these proposals may be accepted and the by-laws altered. The request of the Committee of the Association that the Council would grant to the Fellows a common room in the College has resulted in the adoption by the Council of a resolution to the effect—“That the room adjoining the secretary's office now forming a part of the library not used by readers be furnished as a common room for the use of the Fellows and Members of the College.” Legal opinion was adverse to the appropriation of a room in the College for the exclusive use of a section of the Members of the College. Into the other subjects dealt with in the report it is not necessary to enter. The cardinal fact remains that owing, we may hope, to our own repeated representations and to the perseverance of the Committee of the Association steps have been taken by the Council of the College to establish more satisfactory and intimate relations between the Fellows of the College and the Council. A new departure has been made and it rests with the Fellows of the College generally to improve their position by united action at the meetings of Fellows which will soon be inaugurated. A large accession of numbers to the ranks of the Association and the success of its candidates at the election at the College would speedily be followed by further concessions, which would place the Fellows of the Royal College of Surgeons in a similar position to that enjoyed by the Fellows in the other professional colleges in the United Kingdom.

#### IMPROVED FACILITIES FOR CONTINENTAL TRAVELLING.

##### THE DIEPPE ROUTE.

THE increasing number of travellers between England and the Continent renders any improvement that can be effected in the Channel service a question of considerable importance. Progress has been achieved by leaps and bounds. For instance, if we take the three main routes—Dover and Calais, Boulogne and Folkestone, Newhaven and Dieppe—we find that the number of passengers between England and the Continent by these three routes amounted to 347,923 in 1884. During the year of the great Paris Exhibition the number of passengers was nearly double and attained the extraordinary high figure of 642,465 for the three routes. In 1880 there were 450,779 and in 1891 454,538 passengers. These passengers travelled during the Exhibition year in the proportion of 53.90 per cent. by the Calais route, 17.42 per cent. by the Boulogne route and 28.68 per cent. by the Dieppe route. This latter route found special favour during the Exhibition year and its percentage rose much above the normal. In the previous year (1888) only 17.54 per cent. of passengers went by Dieppe. Those who, for special and temporary reasons, went by Dieppe during the Exhibition year were evidently favourably impressed, for the percentage of passengers going by that route has steadily increased ever since. Thus the percentage of passengers by Dieppe was equal to 21.55 in 1890 and

23 03 in 1891. The statistics of continental travel clearly establish that the Calais and Dieppe routes are becoming more and more appreciated every year. The Calais route will always enjoy the largest patronage because, apart from all other considerations, it involves the shortest sea journey. The new steamers have now crossed from the Calais pier head to the Dover pier head in one hour and ten minutes. Formerly the passage from Newhaven to Dieppe took as long as seven hours in crossing and has sometimes occupied nine hours. The ships were small and narrow and those passengers who were subject to sea-sickness suffered terribly. The route therefore acquired the reputation of being only suited to good sailors and certainly invalids would scarcely venture upon such a journey. Nor were the ports of Newhaven and Dieppe all that could be desired. Consequently in very bad weather there were delays in the departure of ships. Now, however, both ports have been considerably improved; a magnificent breakwater has been built at Newhaven, which effectually shelters the entrance to the port from south-westerly winds while the cliffs close by, at Seaford, break the force of easterly winds. At Dieppe dredging operations, carried out on an extensive scale, render the entrance easy even at low tide.

Of more importance than this consideration is the great improvement effected in the character of the ships now employed on the service. In 1882 two new ships were put on the line. These were called the *Brittany* and *Normandy*. They measure in length 231 feet and their registered tonnage is 240, which is equal to about 520 gross tonnage. These ships have a shallow draft, 7 ft. 6 in., and can carry 578 passengers. In 1888 two ships of a larger model were added to the fleet. These are the *Paris* and the *Rouen*. Their length is 250 feet, their draft 8 ft. 2 in.; their registered tonnage is 326, which is equal to about 700 gross tonnage and they can carry 706 passengers. All these four ships are fitted up in a luxurious manner. They have deck cabins and an upper deck which constitutes a very favourite lounge for passengers. But what is of greater value than all such qualities is the fact that these ships effect the passage in four hours. Indeed, when the season is favourable, and more particularly in the months of July, August, and September, the passage is often accomplished in three hours and a half. Another ship was added to the line last year. This was the *Seine*, and she differed from the other ships inasmuch as she possessed double screw propellers instead of paddle wheels. The *Seine* has effected the passage in three hours and eleven minutes. But nevertheless the venture cannot be spoken of as a success. The speed is unequalled, but in consequence of the shallow harbours the draught is slight and is insufficient to secure steadiness. Therefore there have been so many complaints that the *Seine* was sent into dock for structural alterations with a view of preventing the excessive rolling of the vessel. These new ships have been constructed in such a manner as to secure notable sanitary advantages. Care has been taken to warm and to ventilate the cabins. Under the seats and all round each of the cabins there is a copper coil which during cold weather receives the steam from the engine. Underneath the cabin table are openings through which air, brought down from the deck, enters. All round the ceiling of the cabin, close under the deck, is an exhaust shaft which communicates with the funnel of the steamer. Openings about two inches long and a quarter of an inch wide at a distance of about a quarter of an inch from each other are made by perforating the metallic sides of the exhaust shaft. Thus, all round the cabin the air finds a natural exit which is stimulated by the suction produced in the funnels of the steamer. We noted with pleasure that no difference whatever is made, in respect to warming and ventilation, between the first class and second class cabins. In like manner the closets and the lavatories are the same for both classes. The constructors of these ships have evidently recognised that it is as necessary to observe the laws of health for the poor as for the rich and as much pains are taken to give a plentiful supply of air to the second class as to the first class passengers.

The Dieppe route is now able to offer accommodation as commodious as can be found on any channel steamer. Of the three principal routes to the Continent, the Dieppe has the longest sea and the shortest railway journey. The journey from London to Newhaven is effected under two hours and that from Dieppe to Paris under four hours. The scenery on both sides is undoubtedly the prettiest that exists on any of the routes from London to Paris. On the

English side the passenger, by the payment of one shilling over and above the first class fare, can enjoy the luxury of travelling in a Pullman car. The railway officials are prepared to tender every assistance and facility to invalids travelling by this line. A sort of hammock has been made which can be affixed to the roof of the railway carriage in such a manner that a patient may be carried in his bed from London to the steamer. Finally we should not omit to mention that the ladies' cabins, both in the first and the second class, are of much larger dimensions than were considered necessary in the older steamers. Indeed the ladies' cabin used to be so small and so badly ventilated that many and bitter complaints were made. It is satisfactory to note that the grievances and the hardships attending the Channel passage are rapidly disappearing. Delicate persons need no longer entertain the fears that in the past were quite justifiable. The journey can now be accomplished with so much ease, comfort and rapidity that the apprehensions formerly entertained, when patients were recommended to go abroad, do not apply to the present improved services.

## THE TWENTY-FIRST GERMAN SURGICAL CONGRESS.

EARLY on June 9th the members of the Surgical Congress inspected the hospital at Moabit under the guidance of Professor Sonnenburg. At ten the second meeting of the Congress began in the Langenbeck House. Dr. Güterbock of Berlin showed a case of Empyema. The patient was a man in the prime of life. In the right side of the breast, from the armpit to the girdle, a deep depression was visible, with the operation wound, not yet quite healed, in the middle. The loss of ribs and of a large portion of the lung and the adjacent parts, however, had not in the least impaired the state of the patient's nutrition or the use of the right arm and his appearance was that of a man in excellent health. A considerable number of cases of the removal of tumours from the brain were then discussed and Czerny of Heidelberg expressed the opinion that trephining has a great future as a means of regulating intercranial pressure in mental disease. Pfeilschneider of Schönebeck showed several persons treated by him for fracture or comminution by suture, but this method was condemned by Bergmann and others and only partly defended by Trendelenburg. Küster of Marburg showed a boy in whom a ureter had been successfully resected for stenosis. Schlange of Berlin exhibited several persons who had been cured of actinomycosis. Eyselsberg of Vienna reported a case of this disease which had been cured by injecting tuberculin. Grawitz of Greifswald spoke on the changes of tissues in inflammation and their biological significance and König on the treatment of tuberculosis of the bones and joints, on which subject he is about to publish a book. In the course of the same sitting König proposed the erection in the Langenbeck House of a marble bust of Gustav Simon, who may be regarded as the real originator of the German Surgical Society, for it was he who persuaded the reluctant Langenbeck to found it. After the sitting the members of the Congress dined together in the Central Hotel.

On the 10th some of the members inspected the municipal Hospital am Urban under the guidance of Dr. Körte, others the Emperor and Empress Frederick Hospital under the guidance of Dr. Baginsky and Prof. Gluck, while others were present at a series of demonstrations with the projection microscope given by Dr. Barth of Marburg and Dr. Arthur Hartmann of Berlin. Hartmann's demonstrations had reference to the structure of the skull and attracted great attention. The Congress met at ten. Thiern of Kottbus showed a woman in whom the temporarily applied artificial anus had been reclosed after the healing of a syphilitic ulceration and stricture of the rectum. Trendelenburg followed with a case of flat-foot cured by straightening the foot after chiselling the bones of the leg just above the ankle. On the fact observed by him, that flat feet sweat excessively, Trendelenburg bases the theory that the morbid secretion of sweat is due to a condition of nervous irritation and that perhaps in flat-foot there is abnormal pressure on the nervus plantaris. Professor Albert Köhler showed a young woman who had suffered from stenosis of the pylorus. Before the operation she weighed less than 54 lb

The pylorus was cut out and a new one formed out of the adjacent parts. Half a year after the operation she weighed 84 lb. and now, though convalescence was interrupted by a surfeit followed by severe indigestion, she weighs over 127 lb. The operation-scar in the linea alba is quite firm and solid. The same surgeon showed several cases of amputation in which the patella had been grafted on to the chiselled end of the femur in order to round off the stump better. After Haassler of Halle had shown and commented on a case of gastro-enterotomy, Professor Kraus of Altona showed a woman whom he had cured of very severe faceache and headache by excising the fifth cranial nerve. Madelung of Rostock reported a similar operation performed by him—viz., the extirpation of the third branch of the same nerve. Seuger of Krefeld showed a woman with a burn the size of one's hand on her breast, which had baffled all attempts at cure, owing probably to self-injury on the patient's part. Thiersch related the case of a woman who had frustrated all the efforts of her doctor by always cauterising a skin-wound by means of a piece of caustic soda kept hidden in her dress. Bardenheuer of Cologne reported cases of resection of the upper and lower jaw. A cure of leprosy was also reported. The patient went to Cramer of Wiesbaden, who examined the nerves of the upper arm, and found them softened inside, with leprosy bacilli in them. He removed the smallest of the diseased nerves, split the other two lengthwise, and scraped all the matter out of them. The wound healed and the man was observed for two years. The arm was restored to use, and there was no relapse. After that no more was heard of him but that he had returned to Siam, where he had contracted the disease. Neuber of Kiel spoke of the aseptic treatment of wounds. By certain modifications of the aseptic method, one of which is the keeping of the walls of the operation room moist, he hopes to render the draining of operation wounds superfluous. His main aim is to prevent wound infection from the air of the operation room, which is especially to be feared when operations are performed before many spectators. Schleich of Berlin recommended the cleansing of the field of operation and the surgeon's hands with soap mixed with marble-powder and wax-paste. Arthur Hartmann exhibited his bone preparations and showed a dragoon who had been thrown on his head and dragged for some distance by his horse in the French war. Some years later he began to suffer from headache, which gradually assumed a very threatening form. He was sent from one doctor to another without result, till he came to Hartmann, who discovered suppuration in the frontal sinus. The cavity was opened, the pus removed, and the man permanently relieved.

The afternoon sitting began with a discussion of König's speech of the day before on the treatment of tuberculosis of the bones and joints. Bardeleben reported several cases of resection of the hip-joint in which the restoration of the use of the leg had been extremely successful. One of the patients, a boy, had raced with dogs and beat them. Schleich pointed to the fact that tuberculosis very seldom occurs in fatty organs and recommended the application of fats to tuberculous parts. Schuchardt of Berlin maintained that tuberculosis is transmitted by sexual intercourse. Gurlt then reported on the collective investigation set on foot by the society with a view to getting statistics of narcotisation. In the first year of the investigation 24,625 narcoses were reported, whereas last year, which was the second, 84,605, performed by sixty-two observers, were reported. Of the former number six cases resulted in death, of the latter thirty-three, but it is certain that many of these deaths were not due to the narcotic. In the two years in question the number of cases reported in which chloroform was used was 94,123, in thirty-six of which death ensued—i.e., in one out of 2614. The number of ether cases was 8431, in only one of which death ensued. In 2891 cases mixtures of chloroform and ether were applied and there was one death; in 1380 a mixture of ether and alcohol without deaths; in 2179 bromide of ethyl without deaths; and in 219 the new narcotic called pental with one death. It is pretty certain, however, that the last-mentioned death and that after the use of ether were not due to the narcotics. Among the chloroform cases there were 836 in which Pictet's crystallised ice-chloroform was used. This form of chloroform has a good record, as has also pental, which causes narcosis very rapidly and does not produce several unpleasant by-effects which chloroform does. Ether too has proved a first-rate narcotic. Bromide of ethyl produces only narcosis of short duration up to about three minutes and is therefore most used in dentistry. It is

inapplicable in cases in which laxity of the muscles is necessary, for it does not produce this effect. Bruns proposed that the investigation should be continued for another year on the ground that the material already collected is too scanty. This proposal was carried. König was elected chairman for next year's Congress and accepted the office.

Berlin, June 21st.

## HOSPITAL FOR THE PARALYSED AND EPILEPTIC.

At a meeting, held in the clinical theatre of the National Hospital for the Paralysed and Epileptic on Thursday last, the Right Hon. the Earl of Strafford occupying the chair, Sir James Paget delivered an address in the course of which he said that there were two reasons why he had acceded to the request to speak at the opening of this theatre. He regarded it as a considerable honour to be able to take part in a work of so good a character and it had always been a great happiness to him to know that on the staff of this hospital were numerous and surgeons whom he was happy to call his friends and who were amongst the best promoters of the very highest knowledge in pathology, medicine and surgery and it would be a great happiness to him if he could help the progress of the hospital by speaking of the great good which he had accomplished. He knew of no hospital that had so perfectly fulfilled its purpose as this hospital, which had been associated with charity of the most perfect and hearty kind and with that there had been, as the chairman had pointed out, a constant carrying on of research and teaching, for in the great progress that had been made in the knowledge of the diseases of the nervous system no institution had contributed so largely, both by the opportunities for work which it had afforded and by the kind of work which had been accomplished through its agency. Never a year had passed since the foundation of the hospital without witnessing some distinct and definite increase in the knowledge of medicine and surgery in relation to the brain and the nervous system. If he had a right to speak at all in a place like that it was not for the direct promotion of charity—that could be done more eloquently by others—but he might speak of the way in which charity was dependent for its increase and perfection on the advancement of scientific knowledge. And in relation to that, if the operations now proposed and carried out by Mr. Horsley had been attempted before the foundation of this hospital, it would have been suggested that the brain of the proposer would be the first to require the operation. It was due to scientific inquiry carried on along two distinct lines—lines which seemed in no relation to one another and never likely to converge; and yet these lines had now met and had resulted in the saving of more lives than could now be told. The progress of the knowledge of the nervous system was due to continual inquiry both by scientific research and experiment and by continual clinical observation in the wards, especially in the wards of a hospital such as the National Hospital, in which there were collected large numbers of the rarest cases, such as no private practitioner or general hospital possessed, so that the method of scientific experimental inquiry and scientific medical observation were coöperating, each testing the other and each suggesting to the other what line of inquiry should be followed up in the respective fields of observation. By those means there had been added, year by year, more accurate anatomical and microscopical facts; electricity had been applied more scientifically, and the study of the nervous system had continued all that time, and with all this there had been a constant mutual discussion, each factor testing the value of the other's observation. After alluding to the progress which had been made in neurological science during the last thirty or forty years, Sir James Paget concluded by invoking the fullest blessings upon the hospital and upon the work in which, it is engaged, after which, on the motion of the chairman, seconded by Mr. Victor Horsley, a vote of thanks was passed to Sir James Paget; and on the motion of Dr. Buzzard, seconded by the Right Hon. H. Ryder, a similar vote of thanks was accorded to the chairman.

METROPOLITAN HOSPITAL SUNDAY FUND, 1892.

In addition to the returns published in our last issue giving the amounts collected in aid of the Metropolitan Hospital Sunday Fund, we have received notification of the following amounts. The returns are, of course, as yet incomplete.

	£	s.	d.		£	s.	d.
St. Michael's, Chester-square (Rev. Canon Fleming, B.D.), with additions	1208	15	3	Chigwell Parish Church (Rev. T. Marsden)	23	1	3
St. Jude's, South Kensington (Rev. Prebendary E. Eardley-Wilnot)	1004	10	0	St. Stephen's, South Lambeth (Rev. J. S. Pratt)	20	8	0
Christ Church, Lancaster Gate (Rev. J. C. Ridgway)	1000	17	4	St. George's, Bickley (Rev. R. Wood)	56	10	0
Sir Savile Crossley, Bart., M.P. (a further)	1000	0	0	Christlehurst Wesleyan Chapel (Rev. J. Clarke)	24	0	3
All Saints, Ennismore Gardens (Rev. Ravenscroft Stewart)	440	14	0	Christ Church, Hornsey (Rev. C. W. Edmonstone)	64	15	1
St. Mark's, Hamilton-terrace (Rev. Canon Duckworth, D.D.)	230	2	1	St. Dominic's, Haverstock-hill (Vory Rev. John Procter)	25	2	0
St. Matthew's, Bayswater (Rev. J. Fimer Sullivan)	100	11	0	Horbury Congregational Church, Notting-hill (Rev. H. Hazell)	24	14	7
All Souls, Langham-place (Rev. W. Hay Chapman)	132	10	2	Finsbury Park Wesleyan Church (Rev. J. H. Grubb)	20	4	5
St. Saviour's, Chelsea (Rev. L. C. Walford)	121	13	2	St. John the Evangelist's, Angell Town (Rev. Lancelot L. Sharpe, B.D.)	20	14	11
St. Thomas's, Portman-square (Rev. R. P. Thompson)	117	14	4	Chipping Barnet Parish and District Churches (Rev. D. W. Barrett)	40	7	9
The Theistic Church (Rev. C. Voysey)	107	0	0	St. Paul's, Camden-square (Rev. G. Tiley)	55	8	8
Christ Church, Hampstead (Rev. Geo. F. Head)	136	5	7	The Theistic Church (Rev. C. Voysey), with additions	110	10	6
Grosvenor Chapel, South Audley-street (Rev. W. Foster Elliott)	75	0	0	Westminster Aboey (Vory Rev. Dean Bradley), with additions	185	10	4
Earl of Feversham (a further)	50	0	0	All Saints, Ennismore gardens (Rev. R. Stewart)	470	14	0
Holy Trinity, Marylebone (Rev. A. T. Robinson)	62	4	4	St. Mark's, Hamilton-terrace (Rev. Canon Duckworth), with additions	230	2	1
St. Jude's, East Brixton (Rev. R. B. Ransford)	64	15	0	St. Stephen's, South Dulwich (Rev. J. Meek Clark)	151	2	4
St. Paul's, Wimbledon Park (Rev. E. C. Brace)	59	10	1	Portman Chapel, Baker-street (Rev. Marmaduke Washington)	134	3	1
St. Paul's, Forest Hill (Rev. F. Jones, B.D.)	105	0	3	Holy Trinity, Chelsea (Rev. Prebendary Eytton)	239	1	10
Christ Church, Mayfair (Rev. H. Rowsell)	103	8	1	St. George's, Hanover-square (Rev. David Anderson)	148	7	3
Roslyn Hill Unitarian Church (Rev. Brooke Herford, D.D.)	108	5	3	Christ Church, Streatham-hill (Rev. C. S. Nicholl)	106	10	0
St. Mary Abbott's Parish Church, Kensington, Mission Hall, and Open Air Collection	303	7	7	St. Mary's, Kilburn (Rev. J. Robertson)	102	13	7
St. Paul's (Kensington), Vicarage Gardens (Rev. the Hon. E. Carr Glyn)	80	6	0	St. Columba's, Post-street (Rev. Donald McLeod, D.D.)	102	12	10
Christ Church, Victoria-road, Kensington	82	13	4	St. Phillip's, Kensington (Rev. W. Smale)	107	2	4
St. James's, Holloway (Rev. E. A. Stuart)	80	19	0	All Saints, Martabet-street (Rev. W. A. Whitworth)	68	10	7
Holy Trinity Parish Church, Sydenham (Rev. H. Stevens)	104	0	0	Stamford-hill Congregational Church (Rev. J. M. Gibbon)	95	4	4
St. Barnabas's, Kensington (Rev. Prebendary Thornton, D.D.)	140	14	8	Christ Church, Highbury (Rev. W. J. Chapman)	88	0	10
St. James's, Kidbrook (Rev. J. C. Leeke)	108	8	4	St. Laurence's, Catford (Rev. E. C. Robinson)	26	0	0
St. Luke's, Chelsea (Rev. Gerald Blount)	45	10	0	All Saints, West Dulwich (Rev. J. Beaby)	36	10	0
St. Mark's, Regent's-park (Rev. W. J. Sparrow-Simpson)	25	3	3	St. Stephen's, Portland Town (Rev. F. K. Povah)	34	10	0
St. Stephen's, Ealing (Rev. E. S. Tupholme, D.D.)	91	10	4	St. Mary's, Merton (Rev. E. A. Kempson)	23	9	3
St. Paul's, South Hampstead (Rev. J. W. Bennett)	111	3	3	Willesden Presbyterian Church (Rev. James Durran)	27	10	0
Brixton Wesleyan Circuit (Rev. Enoch Salt)	95	14	10	St. Mary's, Leyton (Rev. J. Lunt)	22	5	6
St. Luke's, Nightingale-lane (Rev. C. M. Erskine Clarke)	41	2	11	St. Andrew's, Streatham (Rev. W. C. Cubison)	38	12	2
St. Paul's, East Molesey (Rev. G. E. Tatham)	23	0	4	Chapel Royal, Hampton Court (Rev. D. Lancaster McAnally)	76	4	4
Raid's Brewery Company (a further)	200	0	0	St. Mary Aldermary and Associated Churches (Rev. Lewis Borrett White, D.D.)	93	11	11
Bloomsbury Baptist Chapel and Mission (Rev. James Ballew)	44	10	9	All Saints, Woodford Wells (Rev. N. R. Fitzpatrick)	22	12	5
Clapham Parish Church (Rev. C. P. Greene)	78	8	8	Holy Trinity, Eltham-road (Rev. T. N. Rowsell)	44	12	9
Church of the Ascension, Blackheath (Rev. W. A. Moberley)	37	2	11	Camden Church, Camberwell (Rev. P. S. O'Brien, D.D.)	61	19	0
St. Augustine's, Queen's-gate (Rev. R. R. Chope)	94	0	0	St. Stephen's, Wandsworth (Rev. C. Caruthers)	50	0	0
Quebec Chapel (Rev. E. B. Outley)	184	0	7	St. John's, Pango (Rev. W. Smyly)	71	0	0
Christ Church, East Greenwich (Rev. Canon Baynes)	40	0	0	St. Augustine, Highbury (Rev. Rev. Gordon Calthrop)	64	0	2
Hendon Churches (Rev. N. W. J. Munt)	40	12	0	R. M.	1	0	0
Finchley Parish Church (Rev. S. Bardalay)	20	1	0	Christ Church, Brondesbury (Rev. C. Dale Williams)	60	5	9
St. Katharine, Royal Collogiate Chapel (Rev. The Master)	33	1	0	St. Mary Boltons (Rev. W. T. Du Boulay)	61	11	6
St. Augustine, Kilburn (Rev. R. C. Kirkpatrick)	58	12	8	St. Mary's, West Kensington (Rev. C. Bradshaw Foy)	51	10	0
Regent's Park Baptist Chapel (Rev. F. B. Meyer, B.A.)	58	10	10	St. Peter's, Streatham (Rev. H. Baron Dickinson)	50	10	6
Holy Trinity, Beckenham (Rev. S. Whitfield Daukes)	35	13	5	St. Saviour's, Aberdeen Park (Rev. J. Bicknell)	32	13	0
Hayes (Kent) Parish Church (Rev. G. Clowes)	20	10	11	Aldenham Parish Church (Rev. Kenneth F. Gibbs)	51	2	0
St. Mary Magdalene, Peckham (Rev. James Seaver)	22	5	0	St. Luke's, Redcliffe-square (Rev. W. F. Handcock)	31	6	8
Christ Church, Marylebone (Rev. E. Venables)	33	5	7	St. Margaret's, Lee (Rev. F. H. Law)	50	3	9
St. Paul, Upper Norwood, morning collection (Rev. W. H. Graham)	101	1	3	Chelsea Old Church (Rev. R. H. Davies)	21	10	1
W. T. Blandford, Esq. (a further)	20	0	0	Farm street Roman Catholic Church (Rev. T. Welsley)	36	8	3
Mrs. Alexander Black	20	0	0	St. German's, Blackheath (Rev. R. Hayes Robinson)	33	19	1
Roehampton Parish Church (Rev. R. Carrington)	52	17	8	Stammore Parish Church (Rev. F. C. Jackson)	42	8	0
St. James's, Piccadilly (Rev. Prebendary Kempe)	105	0	6	St. Matthew's, Upper Clapton (Rev. L. H. Bradford)	74	8	0
St. Gabriel's, Pimlico, and All Saints' (Rev. J. H. J. Ellison)	88	2	11	Clapham Congregational Church (Rev. J. Guinness Rogers, M.A.)	53	0	3
St. Saviour's, Poplar (Rev. J. Beardall)	26	5	0	Essex Unitarian Church, Notting-hill (Rev. R. S. Oakshott)	23	9	2
St. Saviour's, Southwark (Rev. W. Thompson, D.D.)	21	10	10	All Saints, Clapham-park (Rev. A. G. Childstone)	42	1	1
Thomas Ditton Parish Church (Rev. E. H. Rogers)	24	1	6	St. Saviour's, Pimlico (Rev. Henry Washington)	52	3	9
Tooting Graveney Parish Church (Rev. E. H. Morton)	22	0	0	Putney Parish Church (Rev. the Hon. R. Henley)	22	1	3
Highgate Presbyterian Church (Rev. Alex. Ramsay, B.D.)	27	14	3	St. John the Evangelist, Putney (Rev. the Hon. R. Henley)	50	1	0
Church of the Annunciation, Chislehurst (Rev. H. Lloyd Russell)	37	4	8	King's Weigh-house Chapel, Duke-street, W. (Rev. Alexander Sandison)	24	0	0
St. John's, Upper Norwood (Rev. W. F. La Trobe Bateman)	32	13	9	St. Phillip's, Buckingham Palace-road (Rev. W. C. Gibb)	20	4	1
Camden-road Presbyterian Church (Rev. R. M. Thornton, B.A.)	26	7	10	St. Paul's, Clapham (Rev. H. Hughes)	57	14	4
Christ Church (Reformed Episcopal), Harlesden (Rev. J. Anderson)	25	10	2	Christ Church, Lee (Rev. L. A. Smith)	38	4	2
St. Mark's, Tollington-park (Rev. Canon Hurst)	22	13	0	St. Saviour's, Paddington (Rev. M. Tweddle)	86	11	0
Islington Parish Church (Rev. W. P. Barlow, B.D.)	20	11	6	Christ Church, Woburn-square (Rev. J. J. Glendinning Nash)	27	10	0
St. Peter's, Norbiton (Rev. J. Hooker)	20	14	1	St. John the Evangelist, Blackheath (Rev. J. W. Marshall)	46	3	0
St. Peter's, Dulwich-common (Rev. H. J. Pulley)	52	0	0	St. Mildred's, Lee (Rev. F. W. Helder)	34	11	6
St. John's at Hackney (Rev. F. E. Gardiner)	50	5	8	St. Andrew's, Stoke Newington (Rev. H. E. J. Bevann)	26	1	0
				Royal Military Barracks, Wellington Barracks (Rev. R. Arnitage)	40	10	1
				St. Saviour's, Hampstead (Rev. G. A. Herklots)	21	18	3
				Box outside Mansion House, including cheque from J. H. Brown for £2 2s.	25	1	8
				St. Paul's, Shadwell (Rev. Edward Bray)	3	5	3
				St. George's Hospital (Rev. W. Edward Blythe)	2	10	0
				West Drayton Parish Church (Rev. A. W. S. A. Row)	8	5	10
				St. John's Church, North Woolwich (Rev. A. E. Clarke)	2	11	4
				Mr. Thomas Whitby, the Sweep, High-street, Boxley, Kent	0	10	0
				St. Alphage, London Wall (Rev. R. Wheeler Bush, M.A.)	4	0	0
				St. Anthony's Church, Stepney, E. (Rev. W. Gedde)	2	6	2
				St. John's Church, Drury-lane (Rev. E. W. Pownall)	5	2	0
				Mission of the Holy Redeemer, Stoke Newington, N. (Rev. J. A. Le Couteur)	4	0	0
				St. Mary's, Haggerston (Rev. A. Tanner)	4	15	5
				St. Nicholas National Church, Crown-court	1	7	0

Other subscriptions have been received, and will be announced in our next issue.

## ROYAL COLLEGE OF SURGEONS OF ENGLAND.

### ADDITIONS TO THE MUSEUM.

PROFESSOR STEWART, the Conservator to the Museum Committee, is to be congratulated on the success which has attended his labours in the arduous task of obtaining, completing, arranging and describing the very interesting specimens which have been added to the Museum during the past year. The additions to the various departments are more numerous and are probably of a more interesting character than Professor Stewart has had to report upon for any similar period and will, looking to the fact that they include specimens not hitherto in the Museum, prove of great value to the collection.

In the department of pathology the additions, which are numerous, include many specimens illustrative of common diseases, usually classed as medical pathology. It is pointed out by Professor Stewart that for obvious reasons that section of the Pathological Department does not receive proportionately so many contributions as others devoted to purely surgical subjects, and that an attempt has accordingly been made to supply deficiencies in this respect and to render the collection more uniformly representative.

In the pathological series may be mentioned as being of considerable interest the following specimens: Gummatous osteitis of knee-joint, presented by Mr. J. Hutchinson, jun.; bullet impacted in spinal column, presented by Mr. J. W. Hulke; diverticulum of œsophagus, presented by Mr. J. F. Chavasse; peri-œsophageal suppuration from sword-swallowing, presented by Mr. C. Crisp; and foreign body removed from the ear by means of mercury, presented by Mr. A. M. Sheild.

The additions also include a series of microscopical sections, taken from all the specimens of Madura foot contained in the Museum, presented by Mr. A. A. Kanthack, who is of opinion that the fungus found in this disease is indistinguishable from, if not identical with, actinomycosis hominis; and from an independent microscopical examination of the same specimens Mr. J. H. Targett, we understand, is able to support this conclusion.

The cabinet of calculi presented by Sir Henry Thompson, and which now contains one thousand calculi, will prove interesting to many medical men, as it contains a full description of each case.

In the comparative anatomy section over one hundred skeletons and skulls of various mammals, mostly new to the collection, which were presented by the late Sir Victor Brooke, form a most valuable addition to the department. This section includes also two specimens of the remarkable somewhat mole-like marsupial, *Notoryctes typhlops*, which excited so much interest last year; this was presented by Professor E. C. Stirling.

We also note the large and interesting series of additions to the groups of symbiosis and commensalism exhibited at the last soirée of the Royal Society. The additions altogether in this physiological series are of very great interest and importance.

Not the least interesting exhibit is to be found in the additions to the anthropological series, which are numerous, attention should specially be directed to the series of thirteen skeletons and twelve skulls of Ancient Egyptians belonging to the fourth dynasty (not later than 4000 B.C.), presented by Dr. Flinders Petrie.

Looking to the fact that there are so many valuable additions to the collection and also the limited time that the collection is on view—namely (as we announced last week), July 5th, 6th, 7th and 8th—we may strongly advise all who are interested in these professional and scientific subjects to take the opportunity of paying a visit to the Museum.

## THIRD REPORT OF THE SELECT COMMITTEE OF THE HOUSE OF LORDS ON METROPOLITAN HOSPITALS.

THE report contains a summary of the evidence taken by the Committee, who come to the following

### CONCLUSIONS.

#### ENDOWED HOSPITALS.

The Committee observe that only when the endowed hospitals wish to deal with their estates, or to alter the fundamental conditions on which they administer charity, can the Charity Commissioners effectually intervene. The practice is that the endowed hospitals send their accounts annually to the Charity Commissioners; but the action of the Commissioners is limited to receiving these accounts, and the Committee recommend that the Commissioners should have power to audit the accounts and to see that the endowments are applied according to the trust. For the building of St. Thomas's Hospital the authorities had to borrow £100,000 at the rate of 4 per cent., which was afterwards reduced to 3 per cent. St. Thomas's Hospital has £27,000 invested with the Charity Commissioners, and the committee consider that it is to be regretted that by the action of the Charity Commissioners the hospital was prevented from using its own money. In the case of the three endowed hospitals, the Committee are of opinion that the system of administration does not on some points compare favourably with that which exists at other general hospitals. It throws too much power and responsibility into the hands of one individual, the treasurer; though at St. Thomas's Hospital a larger share in the administration is assigned to committees than at the other two. The Committee would especially direct attention to a report by Dr. Thorne (see paragraph 18 of this report), showing that the nursing home at St. Bartholomew's Hospital was in a very unhealthy state, to such an extent that twenty-three nurses and three ward maids were attacked with diphtheria; and also that the drainage arrangements of the three principal ward blocks of the hospital square were defective and "could not be too strongly condemned." The Committee consider that, had there been a large committee of governors alive to the responsibilities of their office, such a discreditable state of things would not have been allowed to occur. It appears in the evidence that the surveyor, a salaried officer, during the three years that he had been in office had never been called upon to make a thorough examination of the drainage of the hospital; and though a report was at length made it was not a thorough report, the excuse being given that it had to be ready by a certain date and that there was not time to make it as thorough as it ought to have been. This neglect is, in the opinion of the Committee, the more inexcusable owing to the affluent circumstances of this charity. The Committee would suggest that in all these endowed hospitals the government should be carried on by a system of weekly boards and subcommittees. As regards St. Thomas's and Guy's Hospitals, the Committee greatly regret to remark that owing to want of funds, occasioned by fall of values, for the most part in agricultural rents, a certain number of beds are obliged to be kept vacant in each hospital, while others are let to paying patients.

#### REMAINING EIGHT GENERAL HOSPITALS WITH SCHOOLS.

The remaining eight general hospitals with schools depend entirely for their support upon voluntary contributions, excepting in a few cases where they possess some small endowment. Their systems of management greatly resemble one another and the evidence shows that they are generally well administered. The Committee note the enormous amount of work done by unpaid boards of managers; and the care exercised, so far as the Committee are able to judge, in the appointment of their medical as well as other officers. The Committee desire to refer to the personal nursing dispute appearing in the evidence of the London Hospital. The authors of these charges were for some time nurses and probationers in this hospital, some of whom did not remain during the whole period of training and of whom two at least stated grievances of their own which were not confirmed by the evidence; and the late chaplain who, for some time before the termination of his connexion in that capacity with the hospital, had differences with the Committee both in these matters and also in regard to the performance of his own duties. The charges are, on the whole, in the opinion of the Committee, not substantiated by the evidence. The evidence in regard to the injury to the health of the "sisters" appears inconclusive. The Committee consider that the difficulties would have been avoided had the governing board, in charge of the hospital at that time, not allowed their authority to fall into the hands of salaried officers. In justice, however, to the London Hospital, the Committee wish to add that it is an admirable hospital, doing work in a part of London where it confers inestimable benefits upon a very large and very poor population. They therefore think it is deserving of the greatest measure of charitable support. The Committee recognise that it is advisable, under present circumstances, to maintain the individuality of these general hospitals, and they consider that the generous rivalry thus promoted tends to medical and administrative efficiency. The Committee suggest that the fact of not holding the diplomas of the Royal College of Physicians and Royal College of Surgeons of London should not exclude practitioners who have graduated elsewhere from becoming members of the staffs of the general hospitals in London. At present at only one general hospital, St. Mary's, are there no restrictions. The Committee would gladly see the restrictions removed at the other hospitals in London.

#### CONVALESCENT HOMES.

The Committee remark that the accommodation for convalescents in connexion with the large hospitals is insufficient, only two or three having convalescent homes attached to them; and that this want is met by the authorities of the hospitals subscribing, through the Samaritan Fund, to convalescent homes. Owing to the scarcity of accommodation the patients, although not thoroughly cured, are discharged, if well enough to leave the hospital. In some cases these patients find their way to the Poor-law infirmaries; in other cases, patients suffering from medical complaints have to be kept for long periods in a hospital, although they would recover more rapidly at a convalescent home in the country. Moreover, these patients have to be provided for in the hospital, to the exclusion of those who would be

**ROYAL LUNATIC ASYLUM, DUNDEE.**—The reports for 1891 submitted to the annual meeting of subscribers held on the 20th ult. were of a satisfactory character. There was an improvement in the financial position during the year; £2000 had been lodged in the bank from ordinary revenue and the building debt reduced by £8295 5s. 8d. The income from the board of patients &c. was £12,283 and the expenditure £12,385; 168 patients had been admitted during the year.

admitted were beds vacant. The Committee avail themselves of this opportunity to direct attention to this need, in the hope that more extensive convalescent accommodation may be provided by philanthropic effort.

#### OUT-PATIENTS AND DISPENSARIES.

The Committee received much evidence on the subject of the out-patient system. On the one hand were set forth the advantages of large out-patient departments for teaching purposes and for the relief of the poor, as they are open at all times day and night, and the great advantage they afford as centres for consultative purposes. On the other hand it was urged that unlimited medical relief was the first step towards pauperising large masses of individuals. The witnesses who held this view pointed out the advantages of provident associations. Those who had not the means to belong to a provident association could obtain medical relief from the institutions provided by the Poor-law. It was suggested that it might be advisable to map out London into districts; and that a person leaving one district and therefore the provident medical association could easily attach himself to the provident medical association of his new district. But the Committee, agreeing that such an arrangement would be highly desirable if it were practicable, doubt whether in London, with its heterogeneous and migratory population, such an organisation would be possible. It is considered by the Committee that by the abolition of the out-patient departments medical education would be seriously interfered with, and further, that on the whole it must be left to the authorities of the hospitals themselves to arrange the organisation of the out-patient department, with the view of rapidly attending to the requirements of the public and of insuring as far as they can that the charities shall not be abused. The Committee are of opinion that the charities are not abused to any serious or appreciable extent, nor do they think that it was by any means proved that patients are carelessly treated, or treated by students instead of thoroughly qualified medical practitioners. The evidence respecting fees appears to show that above the sphere of the poor-law there must exist a large section of the population who cannot afford to pay a doctor in the case of long and serious illness, or in the case of a large family. On reviewing the evidence as to the different systems pursued by the different great general hospitals, the Committee think that, on the whole, the system of limiting the number of out-patients per diem is the most convenient. The Committee consider that inquiries should be made wherever experienced officials think there is cause for suspicion and that the patient should establish a *prima facie* case for charitable relief. It was difficult to obtain from witnesses the exact amount of the work of an out-patient department, because the return of new cases only shows about a third of the work done; it was, however, generally agreed that each patient attended on the average about three times. The Committee do not attach too much importance to the statements as to the reduction of fees of practitioners among the poor by the free work of the hospitals, but it is obvious that the existence of the charities must tend to reduce them. Medical practitioners and the medical officers of free and other dispensaries should be encouraged as much as possible to take advantage of out-patient departments as centres for consultative purposes; and, from the evidence of many hospital witnesses and others, this is already done to a certain extent. In the case of dispensaries and practitioners, the patient might be left in the hands of his medical adviser and not necessarily taken into the hospital.

#### DISTRIBUTION OF HOSPITALS.

The Committee observe with regret that on the south side of the Thames there is very little hospital accommodation compared with that on the north side. St. Thomas's Hospital and Guy's Hospital, already shown to be obliged, for want of funds, to close their doors to many of the sick poor, are the only large general hospitals south of the Thames, but they are situated in the extreme margin of the southern district. One witness from the south side described the medical relief as lamentably deficient; at the same time it was stated that Lambeth Infirmary was full. On the north side of the Thames, especially in the region of Soho, there is great congestion of hospital accommodation. It was stated by a witness that within one mile of the Middlesex Hospital (Berners-street, Oxford-street) there are over 2050 hospital beds, as well as 13 dispensaries of various kinds; in fact, that by far the greater proportion of the institutions for medical relief are within an area of two miles square. In addition to this local accommodation for the sick, there is the Marylebone Infirmary at Notting-hill, where there is accommodation for 650 patients; Paddington Infirmary, 180 beds; and Central London Sick Asylum, 204. It was suggested that certain hospitals might be removed from places where they are not so much required to localities where the accommodation is deficient. The Committee cannot regard this suggestion as practical, but they would strongly advise that more hospital accommodation should be provided south of the Thames, and were it possible to find the site, and were philanthropic endeavours to be made for further accommodation for the sick in London, a large general hospital, say in the densely populated district of Camberwell, would no doubt be of extreme value. The Committee do not lose sight of the tendency of individuals to prefer some particular hospital, and many instances were given of patients passing four or five hospitals on their way from their homes to a particular hospital in which they had confidence. Though the Committee cannot doubt that this is a fact, and that possibly this migratory disposition would not be checked by the building of a large general hospital, they are nevertheless convinced that more hospital accommodation is required south of the Thames.

#### EDUCATION.

The Committee had before them all the deans of the medical schools and heard opinions from some prominent members of the profession. Many witnesses put forward views in favour of and against central colleges for the teaching of certain subjects. The Committee consider it well worthy of consideration whether it would not be advantageous that the medical schools in London should affiliate themselves to a teaching university or organisation, after the nature of colleges in a university, with the view to the securing first-rate lecturers for the subjects which can be taught in classes as distinguished from clinical instruction. The Committee observe that a very useful field for medical instruction is at present closed to students—namely, the Poor-law infirmaries could be usefully opened for clinical instruction. In this the Committee heartily concur. In addition to the large

field for instruction which would thus be opened, they agree with the opinions expressed that the presence of students in the practitioners stimulating, by reason of the observation and criticism which are brought to bear on diagnosis and treatment; and the evidence they have received shows that where a system of clinical classes of students is carried out under proper regulations the patients have no objection to students at their bedside. It appears that there are only three hospitals where female clinical clerks are employed—the Hospital for Children in Great Ormond-street, Royal Free, and New Hospital for Women. Witnesses from these hospitals testify to the ability and address with which the duties of such clerks are performed.

#### SPECIAL HOSPITALS.

The case of special hospitals and the arguments urged for and against this class of hospital are summarised in the preceding pages. Hospitals for certain diseases of patients—for example, for children—do not appear to the Committee to be open to the criticisms made on special hospitals. Lock hospitals form a separate subject for consideration. The Committee think that the nature of the disease and the character of the patients make it desirable that they should be treated in separate buildings, or, at all events, in separate wards from other patients. The Committee have had their attention particularly directed to the fact that patients in these hospitals are in the habit of quitting the hospital in a diseased state on such occasions as the Derby week, fairs, &c., for the purpose of pursuing their avocation. The Committee recommend that provisions analogous to those which prevent a patient leaving a hospital when suffering under infectious diseases should be extended to certain venereal diseases. Objection is made to special hospitals on the ground that exclusive attention to a particular disease tends to narrow the mind and to induce a specialist to imagine that all complaints are in some measure connected with the disease to which he has devoted so much attention. It is obvious that there is a certain tendency in any special study to narrow the mind, but any such consequence is practically avoided if the practitioner goes through a sufficient course of general hospital and other general practice before he elects to devote himself as a specialist to a particular disease. It is impossible to prevent the natural consequences of the great competition in London to force men into eminence in respect of their special knowledge and familiarity with particular complaints. After all the evidence presented to them it seems to the Committee that the hostility, so widely shown by the medical profession to special hospitals, arises from the fact that numerous small hospitals for special diseases have been instituted by medical men for the purposes of their own advancement, and that such a course of action leads to the establishment of hospitals where they are not wanted, to waste of money incident to the creation of badly managed and small institutions, and to the deception of the public by inducing them to subscribe to undertakings alleged to be of public benefit, but which are in reality mere schemes for private emolument, and also are useless for teaching purposes. The Committee consider that the charge of abuse is substantiated in regard to some small special hospitals. This class of small special hospitals to which the Committee refer, of which examples appear in the evidence, the Committee do not consider of any real benefit either to the sick or to science. They appear to be carried on sometimes in incommensurate buildings or under unsanitary conditions, and the Committee would deprecate the multiplication of such institutions. The Committee think it their duty to invite particular attention to the case of the Royal Hospital for Incurables at Putney. While in receipt of very large support, having a surplus in 1890 of £16,000, the authorities of this hospital appear to be incapable of effecting reforms and are extremely resentful of external observation. In regard to this hospital the Committee would strongly recommend reforms in this direction:—That a resident medical officer should be appointed with general control in absence of the Committee, as is the case in the Poor-law infirmaries; that a ladies' committee should be appointed, as a large majority of the patients are females; that all nurses should be hospital trained; that the contracts for food and stores of all kinds should be by open tender; and that the general supervision by the committee of governors should be greatly increased. The objects of this charity are excellent, but until the management is thoroughly reformed the Committee regret that they feel bound to add that the institution is not one which can be commended.

#### ACCOUNTS.

The Committee observe with satisfaction that, since the opening of this inquiry, a committee, comprised of the secretaries of some of the principal London hospitals, has been considering the subject of a uniform basis of accounts, a copy of which appears in Appendix A to the report. The Committee are glad to notice that those best acquainted with hospital accounts have recognised the advisability of a uniform system. The Committee consider that, for accuracy, further subdivision on the expenditure side might be advisable—as, for instance, "firing and lighting"; also "wines and spirits" might be tabulated separately. Under heading VI. it might be well to state, for the information of the public, for whom the "salaries, wages and pensions" as well as "other salaries, wages and pensions" are charged. It might be worth while for the committee of hospital secretaries, if it renews its sittings, to consider whether the totals might be stated on one page, with letters referring to schedules, where the items of expenditure might be set forth in greater detail. In the evidence before the Committee mention was made of the difficulty of ascertaining the cost of an out-patient, without which calculation any estimate of the cost "per bed" is unreliable. The Committee do not think the difficulties insurmountable. The main difficulty appears to be to separate the accounts of the dispensaries into two parts—the in-patient and out-patient; this once arranged, the reliable cost per bed might be ascertained. The Committee consider that this difficulty might be met thus—an account might be kept of any drugs supplied for the in-patients; the difference between the total dispensed and the amount supplied to the in-patients would be the amount supplied to the out-patients. The wages of the nurses in the out-patient department and the wages of the scrubbers, porters, &c., employed could be charged to the out-patient department. The proportion of rates and taxes might be estimated by the proportion which the space allotted to the out-patient department bears to the whole hospital.

#### CONTRACTS.

The Committee consider that all contracts should, as far as possible,

be by public tender, according to the practice enforced by the local board in regard to poor-law infirmaries.

#### COÖPERATION.

The Committee regret to remark that there does not seem to be any genuine wish for coöperation between the various kinds of medical institutions. They are of opinion that much more might be done than at present by the hearty coöperation between the special hospitals and general hospitals, between dispensaries of all kinds and general hospitals, and between general practitioners and general hospitals. It would be an early duty of a central board to devise some scheme to further such coöperation.

#### NURSING.

The subject of nursing is treated at length on pages 73 to 85. A certain amount of variety exists as to the hours of employment of nurses in the general hospitals in London. The Committee consider that eight hours' work, exclusive of the time for meals, is, as a rule, as much as should be required from nurses in these hospitals. In constructing future hospitals care should be taken that sufficient accommodation for nurses be provided to allow of the hours of nursing being reduced. They would suggest that every nurse in the large and busy hospitals in London should have at least two days off in the month and that the period of holiday should not be less than three weeks; that not less than one full hour should be allowed for dinner; and while, on the whole, the food of the nurses appears to be good, yet, from the nature of the occupation of nurses, special care ought to be exercised that as well as being sufficient in quantity and in quality it should be served in an appetising manner. In bringing about this end the Committee are strongly of opinion that at the nurses' dinner one of the head officials of the hospital should preside, and that the dinners should be frequently visited by members of the governing body. The Committee note with satisfaction the great preponderance of opinion that the health of nurses in London is good. The Committee think it very desirable that, where the funds of the hospital permit, pensions should be provided for nurses, whether by the hospital following the example of the London and Guy's Hospitals, by joining the National Pension Fund for Nurses, or by the hospital providing a special pension out of its own funds. Nurses in the wards should not have their duties increased by doing menial work, such as scrubbing and cleaning grates and lavatories or other services of a like nature. For that purpose, as is the case in most hospitals, the class of servant termed "ward maids" or scrubbers should be employed. While the Committee recognise that the matron must be greatly responsible for the appointment and dismissal and general conduct of the nurses, they are strongly of opinion that no absolute power ought to be given to any matron, but that the appointments and dismissals should be made by the chief executive authority of the hospital. It is to be observed that many hospitals send out nurses after a certain period of training at sums varying from one guinea to three guineas a week to private patients. That these nurses bring considerable addition to the funds of the hospital there can be no doubt. The Committee consider that this is a good practice, but that, to prevent the wards from being denuded of nurses in order to bring funds to the hospital, a separate staff should be employed for this purpose. They are of opinion that the minimum period after which a nurse can be advertised as thoroughly trained, is three years; and considering the large amount of money these nurses can earn for the hospital, the Committee think that a sliding scale commission on their earnings, mentioned as being in practice at one of the large general hospitals, would be a fair addition to their regular hospital wages. It appears that at the London Hospital, in the form of certificates for nurses, certain blanks may be filled up in different ways according to the discretion of the matron. The nursing capabilities and conduct of the nurse may be described respectively as "excellent" and "exemplary," which constitutes a first-class certificate, or as "good" in both cases when the certificate ranks as second class. It would seem that the latter form is used when the matron is not so well satisfied with a nurse; and the Committee think that words indicative of inferiority should be inserted in all certificates below the best, if, indeed, it is desirable that any such certificate should be issued at all. In regard to male nurses, who appear to be only employed in cases of violent patients, with the exception of two hospitals, every care should be exercised to secure the services, if not of duly qualified men, of well-known and thoroughly trustworthy persons, having, if possible, some experience. Nursing in the Poor-law infirmaries differs in various institutions. In some a large proportion of nurses are hospital trained; but the Committee regret to find that one half of the matrons are not regularly trained nurses. The Committee are strongly of opinion that not only all matrons but that all nurses in a Poor-law infirmary should be trained nurses; the Committee would recommend that no nursing whatever should be done in infirmaries by paupers. The Committee remark that there is no separate infirmary at Bethnal-green and they observe with surprise and regret that there appears to be in the sick wards in this workhouse a regular staff of less than twenty nurses, some of whom are sixty-five years of age, and that as many as eighty paupers are employed as nurses. The Committee consider that the number of nurses should be increased throughout the infirmaries and that infirmaries should train their own nurses. This system already exists at one of the largest infirmaries in the metropolis.

#### POOR-LAW INFIRMARIES.

On the whole, the Committee are inclined to think that the system of organisation which places the resident superintendent in charge of the whole institution is a good one. The Committee agree in the suggestion of Miss Twining, that lady inspectors for infirmaries, especially as regards the nursing department, would be a valuable addition to the staff of the Local Government Board. The new Poor-law infirmaries established since 1867 appear to the Committee, so far as they are able to judge from the evidence, to be well-managed institutions. They think that further accommodation is required, as it was pointed out that a large number of sick poor have to be treated in the sick wards of certain workhouses. The medical supervision is less efficient in the workhouse, while the nursing is altogether inferior. The Committee concur in Dr. Bridge's suggestion that the accommodation in infirmaries should be increased so as to take the patients who are now housed in the workhouses. A notable instance exists in the case of the three unions, the Strand, St. Giles's and St. James's, which have but a single infirmary between them, the London Central Sick Asylum containing

only 264 beds, as has been observed above, while Bethnal-green has no infirmary whatever. The Committee observe that, although strong representations have already been addressed by the Local Government Board to the guardians of Bethnal-green with a view of increasing their sick accommodation, no steps have yet been taken to remedy the defect; and they are of opinion that if the powers of the Local Government Board are insufficient to enforce a proper provision for the sick, they should be extended.

The want of accommodation for the sick is also notable as regards the Whitechapel district, where it appeared that at times the infirmary has 10 per cent. more patients than its proper complement.

#### HOSPITAL SATURDAY AND SUNDAY FUNDS.

The Committee think the public might subscribe more freely to the Hospital Saturday and Sunday Funds could they believe that by these organisations they were really enabled to discriminate between those hospitals which are worthy and those which are unworthy of support. The system of distributing the Sunday Fund on the principle of "work done," and the Saturday Fund on that of "relief afforded," appears to be open to the objection that it is a premium on competition for patients; and that it tends to stimulate the discharge of patients before the cure is complete, with a view to show as large a return as possible of patients in the year.

#### PROPOSED CENTRAL BOARD.

Various proposals for a central board are set out on pages 44 to 47 of this report. The Committee do not incline absolutely to any one of these proposals. They are of opinion that, as there is no Government grant, the interference of a Government officer for inspection would be unwise, and they think such interference would tend to check the flow of voluntary contributions and to some extent to interfere with the responsibility of the unpaid boards of managers. The Committee do not think that such a central board should be given any statutory powers as regards the formal licensing of any hospital built, or about to be built. They would recommend that the proposed central board should be granted a charter to entitle it to receive endowments, legacies, bequests and contributions for distribution to medical charities and to meet its own necessary expenses. The board might be organised in the following way:—The various hospitals and dispensaries of all kinds should be grouped. The smaller hospitals should be grouped according to the classes of disease which they treat. Each general hospital, with or without a school, might be considered to be equivalent to a group. Each group would send one or more delegates to be members of the central board. The heads of the great medical corporations—e.g., the Royal Colleges of Surgeons and Physicians, the Medical Council and the Society of Apothecaries—might become members of this central board. The free and part-pay dispensaries might send one member and the provident dispensaries also one member. The Hospital Saturday and Sunday Funds might each send one member. A table (marked "A") is attached, suggesting details for the formation of such a board. The duties of this board might be of the following nature:—(1) It should receive annual reports, statements of accounts and balance-sheets from all hospitals and dispensaries, together with a return of the total number of in-patients, out-patients, and casualty patients. (2) It should require that all accounts be audited by competent chartered accountants. (3) It should arrange that all medical charities should be visited and reported on periodically. (4) It should report from time to time, as occasion required, all proposals for new hospitals. (5) It should publish an annual report, the principal heads of which might be as follows:—(a) A complete statement as to the pecuniary position of each medical charity. (b) A statement by a competent authority as to the existing sanitary condition and ventilation of each hospital and as to arrangements concerted with the Metropolitan Fire Brigade. (c) An account of the number of beds in use, the number of beds unoccupied, and the reasons why they are unoccupied. The average daily number of occupied beds, details as to beds for which payment is made, and the number of resident medical staff, resident officers, nurses and servants. (d) A statement as to the method according to which each hospital deals with its out-patients and casualty patients and the number of each. (e) Proposals for the removal of hospitals and dispensaries to places where further hospital or dispensary accommodation is required and the proposals for the establishment of new hospitals, and all other matters of interest relating to the treatment of the sick poor. (f) The nursing at hospitals and the proceedings of nursing associations in the metropolis. (g) The proposed board should early turn its attention to the possibility of so organising medical charity as to secure their coöperation with one another and the coöperation of medical charity with general charity.

While this board would not have any direct or legal power to stop the building of a new hospital, or to amend systems of organisation in existing institutions, the Committee think that the fear of adverse comment in the reports of the board, or omission from recommendation in those reports, would have a powerful influence in preventing the building of useless hospitals and in securing proper administration in existing institutions. The Committee think that the board should assist and work with the managers of the Hospital Saturday and Sunday Funds, and that in addition to the caution which is exercised by the administrators of those funds no grant should be made to any institution whose application was not endorsed by the central body. There can be little doubt that in times of pecuniary difficulties of any individual hospital or group of hospitals appeals to the public would have greater weight were they supported by a body of responsible men who were conversant with the merits and the means of all the medical charities in London. The expenses of this board might be defrayed by levying a small percentage on the income of each group of hospitals sending a delegate to the board. In sketching the foregoing outline of a central body, the Committee are desirous of expressing their opinion that some more satisfactory organisation of medical charity is most desirable. It should always be borne in mind that the establishment of Poor-law infirmaries and rate-supported asylums, under the Metropolitan Poor-law Act, 1867, has in great measure altered the relations between the poor and the hospitals and everything associated with medical charity; and the Committee cannot shut their eyes to the possibility that if some such organisation as they have recommended is not adopted, a time may come when it will be necessary for hospitals to have recourse either to Government aid or municipal subvention. It is shown by the evidence that, apart from the three endowed hospitals, the general hospitals

in London are maintained principally by the legacies they receive and large donations from unexpected quarters. In most cases the subscriptions from annual subscribers do not suffice to pay the wages of the servants and nurses employed in the service of each hospital, to say nothing of the cost of maintenance and administration. It has been authoritatively stated that from £50,000 to £55,000 per annum are required to render available the 1800 or 2000 vacant beds which are said to exist. One endowed hospital is maintained entirely by its endowments, but the two others are so short of funds that many beds are closed to the sick poor. It but remains for the Committee to acknowledge the readiness with which the authorities of the medical charities and of the Poor-law institutions have laid before them all the information desired.

TABLE A.—Suggested Grouping of Hospitals for the purposes of Representation on the proposed Central Board.

## Public Health and Poor Law.

### LOCAL GOVERNMENT DEPARTMENT.

#### REPORTS OF MEDICAL OFFICERS OF HEALTH.

**Barnsley Rural District.**—Changes in the area of this district make statistical comparisons with previous years somewhat difficult. The general death-rate, which was influenced both by measles and influenza, was 18·8 per 1000 last year. School attendances, both as regards teachers and scholars, had to be interfered with by reason of scarlet fever and measles, and a certain number of patients, including four cases of enteric fever and one of small-pox, were removed to the Kendray Hospital. Dr. Sadler naturally finds grave fault with the Yorkshire midden-privy and the nuisance necessarily arising from it; he also refers to bad scavenging at Darfield and Cudworth. Extension of sewers is in progress, drain defects continue to be remedied and by-laws as to slaughter-houses are to come into operation. Other improvements are still called for and amongst these is the substitution of a proper water-supply for that derived from local wells in certain localities, such as Royston.

**Plymouth Urban District.**—Mr. F. M. Williams has evidently performed his duty towards Plymouth in pointing out its gravest sanitary defects. The "wall sewers," which are but elongated cesspools, together with inefficient drainage, ventilation, water-supply, &c., are naturally found to be associated with high death-rates; and it is satisfactory to learn that as regards the sewers a new scheme is in prospect. Mr. Williams objects to the ventilation of sewers on to the level of narrow streets. In this respect he by no means stands alone, but when he explains that it is a paradox to

allow this as regards sewers and to require soil pipes to be ventilated by shafts "carried above all windows," it may be argued that the two things not are quite comparable. Soil pipes ought not, according to modern by-laws, to receive air from the public sewers; they should only contain the current of air, largely fresh air, which courses through each separate house drain and this drain is in turn aerially cut off from the sewer. Thus to admit the air of one's own house-drain at a level above house windows is a different thing from receiving the air of public sewers, which may contain infectious excreta in abundance at the same point. This, indeed, is one of the difficulties in finding an acceptable alternative to the system which Mr. Williams and others condemn. The general death-rate for 1891 was 22·5 per 1000 and the infantile death-rate was abnormally high, a result which, apart from other circumstances referred to in the report, cannot be dissociated from the prevalence of insanitary conditions. Public health matters are, we trust and believe, now receiving much attention in this important borough, and amongst other matters we are glad to note that the long-needed means for properly isolating cases of infectious diseases are about to be provided. Action is also being taken under the Housing of the Working Classes Act.

**Wirksworth Urban District.**—According to Mr. Broster the death-rate of 17·4 per 1000 last year, whilst marked by an excess of death amongst old people, was attended with a diminished amount of death in infants. The infectious diseases notification system seems to work well, but there are no adequate means for isolation and disinfection; and to provide such means in a proper way is held to be beyond the resources of the district. Combination between adjoining districts is hardly likely to be made voluntarily, and hence Dr. Broster favours the formation of joint districts for such purposes by the County Council, much on the same lines as those set out in Lord Thring's Bill just submitted to the House of Lords. House accommodation for the lower classes is bad in the district, but it is hoped that new erections will be properly controlled by the by-laws. Questions of water-supply and sewerage are engaging the attention of the authority.

**Stroud Rural District.**—For the eighteenth year Mr. T. Partridge makes his annual report on this district. Diphtheria prevailed to an exceptional extent, the disease being found in association with insanitary surroundings and dampness of houses due to faulty foundations or to walls abutting on adjacent banks; it is also suggested that the existence of scarlet fever produced faucial lesions favourable to the reception of the diphtheria contagium. Public water-service is being extended in the district and other sanitary work is steadily in progress. The general death-rate and the zymotic rate were 18·4 and 1·5 per 1000 living respectively.

**Watford Urban District.**—Dr. Brett gives the death-rate for 1891 as 12·9 per 1000 and the zymotic death-rate was low. The isolation hospital is well spoken of, although the scarlet fever pavilion is looked upon as temporary. Since the report was written difficulties as to scarlet fever isolation in the rural district have arisen and if the joint action between the two authorities advocated by Dr. Brett is maintained it is to be hoped that something more than temporary provision will be made. The report does not this year contain much information as to sanitary circumstances or improvements in the district.

**Thingoe Rural District.**—Dr. C. S. Kilner discusses the vital statistics of the district somewhat carefully, and gives the death-rate for 1891 as 15·2 per 1000 living, the zymotic rate being 0·57. Infectious diseases have, as will be gathered, been by no means frequent, and typhoid fever, the disease which is most intimately influenced by sanitary measures, was practically absent. There were, however, 14 cases of scarlet fever, a number quite large enough to start an epidemic, hence the recommendation to provide means of isolation in advance. The water supplies, some of which are hardly of the best, are looked after; dwellings are supervised with a view to their being made fit for human habitation; and some very interesting proceedings are recorded in connexion with action taken under the Housing of the Working Classes Act, 1890, which has ended in the burden of the expenses for building certain new houses being cast on the whole of the Thingoe Union.

**Bilston Urban District.**—Of 92 notifications during 1891 63 had reference to scarlet fever, and of these 28 patients were removed to a temporary cottage hospital, no death occurring. The hospital was thus very useful, but Dr. Bailey reminds the sanitary authority of the need for a per-

manent building, adequately arranged for its intended purposes. Houses have been condemned and otherwise dealt with; the closet arrangements need to be brought under one system, and the water-carriage system, combined with automatic flush arrangements, is advocated for the houses of the labouring classes. The death-rate was high—namely, 23·6 per 1000; and the rate of death in infants was excessive, even in view of the fact that young mothers are much employed in factory labour.

*Uverstono Rural District.*—Dr. A. Thompson calculates the death-rate as 14·4 per 1000 last year. Of 106 notifications 69 were of scarlet fever and 27 of typhoid fever. As regards the latter, it is stated that the water-supply was often found unsatisfactory, but that this has been remedied. It may be hoped that the supplies will be maintained under constant supervision so as to prevent such a result in the future.

*Grange-over-Sands Urban District.*—The main drainage has been completed in this district, scavenging is in part carried out by the authority and improvement in the water-supply is in prospect. In short, this place bids fair to have an excellent reputation. The death-rate, according to Dr. A. Thompson, was 10 per 1000 in 1891.

### VITAL STATISTICS.

#### HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6782 births and 3377 deaths were registered during the week ending June 25th. The annual rate of mortality in these towns, which had been 17·8 per 1000 in each of the preceding two weeks, declined last week to 17·3. In London the rate was 17·3 per 1000 and corresponded with the mean rate in the thirty-two provincial towns. The lowest rates in these towns were 8·8 in Croydon, 11·2 in Wolverhampton, 11·6 in Brighton and 11·9 in Leicester; the highest rates were 21·1 in Manchester, 21·5 in Salford, 22·7 in Huddersfield and 22·9 in Oldham. The 3377 deaths included 477 which were referred to the principal zymotic diseases, against 466 and 514 in the preceding two weeks; of these, 176 resulted from measles, 99 from diarrhoea, 84 from whooping-cough, 50 from diphtheria, 47 from scarlet fever, 19 from "fever" (principally enteric) and 2 from small-pox. No fatal case of any of these diseases occurred last week in Huddersfield or in Gateshead; in the other towns they caused the lowest death-rates in Croydon, Leeds and Newcastle-upon-Tyne, and the highest rates in Manchester, London, Oldham, Preston and Halifax. The greatest mortality from measles occurred in London, West Ham, Manchester, Sunderland, Birkenhead, Oldham, Birmingham and Halifax; from whooping-cough in Salford, Bristol, Preston and Hull; and from diarrhoea in Blackburn, Norwich, Birmingham and Plymouth. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 50 deaths from diphtheria included 39 in London and 4 in Manchester. A fatal case of small-pox was registered in London and one in Liverpool, but not one in any other of the thirty-three large towns; 56 cases of this disease were under treatment in the Metropolitan Asylum Hospitals and 6 in the Highgate Small-pox Hospital on Saturday last. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2066, against numbers increasing from 1226 to 1945 on the preceding thirteen Saturdays; 284 new cases were admitted during the week, against 207 and 213 in the previous two weeks. The deaths referred to diseases of the respiratory organs in London, which had declined from 304 to 202 in the preceding six weeks, further fell to 181 last week and were 35 below the corrected average. The causes of 49, or 1·5 per cent., of the deaths in the thirty-three towns were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Portsmouth, Bristol, Bradford, Newcastle-upon-Tyne and in thirteen other smaller towns; the largest proportions of uncertified deaths were registered in Liverpool, Salford, Blackburn and Hull.

#### HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 20·8 and 17·7 per 1000 in the preceding two weeks, rose again to 19·3 during the week ending June 25th and exceeded by 2·0 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 13·7 in Perth and 16·5 in

Greenock to 20·0 in Aberdeen and 21·1 in Glasgow. The 538 deaths in these towns included 35 which were referred to measles, 27 to whooping-cough, 11 to diarrhoea, 8 to diphtheria, 3 to scarlet fever, 1 to "fever," and not one to small-pox. In all 85 deaths resulted from these principal zymotic diseases, against 82 and 66 in the preceding two weeks. These 85 deaths were equal to an annual rate of 3·1 per 1000, which exceeded by 0·7 the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had been 27 in each of the preceding two weeks, rose again to 35 last week, of which 31 occurred in Glasgow and 3 in Edinburgh. The deaths referred to whooping-cough, which had been 30 and 27 in the previous two weeks, were again 27 last week and included 22 in Glasgow and 3 in Edinburgh. The fatal cases of diphtheria, which had been 2 in each of the preceding two weeks, rose to 8 last week, of which 3 occurred in Aberdeen, 2 in Edinburgh and 2 in Glasgow. The 3 deaths from scarlet fever showed a slight further decline from recent weekly numbers and included 2 in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 124 and 94 in the preceding two weeks, further declined to 80 last week and were 47 below the number in the corresponding week of last year. The causes of 43, or more than 8 per cent., of the deaths in these eight towns last week were not certified.

#### HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 24·0 and 31·6 per 1000 in the preceding two weeks, declined again to 27·4 during the week ending June 25th. During the first twelve weeks of the current quarter the death-rate in the city averaged 31·9 per 1000, against 19·0 in London and 17·9 in Edinburgh. The 184 deaths in Dublin during the week under notice showed a decline of 28 from the number in the preceding week and included 24 which were referred to measles, 5 to whooping-cough and not one either to small-pox, scarlet fever, diphtheria, "fever," or diarrhoea. In all, 29 deaths resulted from these principal zymotic diseases, equal to an annual rate of 4·3 per 1000, the zymotic death-rate during the same period being 3·1 in London and 1·8 in Edinburgh. The fatal cases of measles, which had increased in the preceding three weeks from 21 to 27, declined again to 24 last week. The deaths referred to whooping-cough, which had been 1 and 5 in the preceding two weeks, were again 5 last week. The 184 deaths registered in Dublin last week included 29 of infants under one year of age and 43 of persons aged upwards of sixty years; the deaths of infants showed a slight decline, while those of elderly persons showed a further increase upon recent weekly numbers. Four inquest cases and 2 deaths from violence were registered; and 55, or nearly a third, of the deaths occurred in public institutions. The causes of 14, or nearly 8 per cent., of the deaths in the city last week were not certified.

#### CALCUTTA

The total number of births registered in February was 647, giving an annual ratio of 16·6 per 1000 of population. Of the 647 births 324 were males and 323 females. The total number of deaths (exclusive of stillbirths) registered in February was 1199, against 1302 in the preceding month showing an annual ratio of 30·8 against 33·4 per 1000 of the population. The proportion of male to female deaths was as 138 to 100. The monthly total was higher than all the corresponding figures of the past decade, excepting 1890 and 1891. There were 85 deaths from cholera, against 57 in the preceding month. The number is less than all the corresponding figures of the past ten years, excepting 1886 and 1887. There was only one death from small-pox registered, and one in the previous month. The deaths from fevers amounted to 455, against 497 in the previous month. The total exceeds all the corresponding figures of the past decade. There were 32 deaths from tetanus in the month, 24 of which were under one year of age. The mortality of infants under one year of age reckoned on estimated births was 277·9 against 287·2 in the preceding month per 1000 of population per annum. In the amalgamated area of suburbs there were 366 births registered in the month, giving an annual ratio of 20·4 per 1000 of population. Of these 203 were males and 163 females. The total number of deaths registered in February was 721, giving an annual ratio of 40·2 per 1000 of population. Of these deaths 40 were from cholera, 339 from fevers, 79 from bowel complaints, 42 from tetanus, 13 from injuries and 208 from other causes.

## THE SERVICES.

## MOVEMENTS IN THE ARMY MEDICAL STAFF.

Surgeon-Major F. W. Trevor has been transferred from Aldershot to Woolwich.—Surgeon-Major J. E. Nicholson has arrived at Hong-Kong in relief of Surgeon-Lieutenant-Colonel Barrow.—Surgeon-Major Murphy, Senior Medical Officer of the Royal Arsenal, died on the 24th ult.—Brigade-Surgeon-Lieutenant-Colonel F. Howard, in charge of the Station Hospital, Belfast, has proceeded on leave of absence.—Surgeon-Lieutenant-Colonel Charlton, in charge of the Station Hospital, Athlone, has proceeded on leave.—Surgeon-Captain L. E. Anderson has joined at Whitley Camp from York for duty with Militia.—Surgeon-Captain J. V. Savaige has been invalided to England from Ceylon.—Surgeon-Captain A. Perry has arrived in Ceylon.—Surgeon-Captain O'Callaghan has arrived in England on leave of absence from Cyprus.—Surgeon-Captain J. Ritchie has obtained leave of absence from Malta for four months.—Surgeon-Captain A. Baird has proceeded from Devonport to Leigh-hill Camp with Militia, and Surgeon-Captains J. H. Brannigan, C. Gerner and H. B. Mathias to Hay Camp, Monmouth and Brecon respectively.—Surgeon-Captains Bayler, Power, Jameson and Sandiford have proceeded from Cork to Nenagh, Wexford, Kilkenny and Glenburgh respectively, on Militia duty.—Surgeon-Captains F. W. Begbie, Dunn, Tyacke and Burchall have proceeded from Portsmouth to Montrose, Haddington, Edinburgh and Wicklow respectively on Militia duty.—Surgeon-Captain C. J. Woods has been granted sick leave from Gosport.—Surgeon-Captain R. C. Johnston, Thames District, has been granted leave pending retirement.—Surgeon-Lieutenant-Colonel Dwyer has joined the Home District for temporary recruiting duty and Hon. Deputy-Surgeon-General Don has proceeded on leave.

## DEATH OF SIR WILLIAM AITKEN.

In consequence of the death of Sir William Aitken and the retirement of Dr. Allman, the post of Examiner in Chemistry and Natural Science at the next examination of candidates for the Army Medical Service will, it is understood, be filled by Dr. T. W. Shore, of St. Bartholomew's Hospital, and that of Examiner in Medicine by Dr. W. H. Allchin.

## ENTERIC FEVER IN INDIA.

We are glad to see that this subject is exciting the attention of the Indian press. We have so frequently adverted to it that there remains little or nothing to add to our previous remarks. Quite recently the deaths of three young officers from this disease have been announced in three separate localities. Enteric fever is notoriously the most fatal disease to which the young and newly arrived European soldier is exposed in India; and its spread seems to have been rapidly increasing in that country of late years. No doubt the numerical increase is partly attributable to a more careful diagnosis and to the fact that the true nature of the milder forms of the disease are recognised and correctly returned; but this does not by any means explain the large and increasing mortality and sickness attributable to typhoid fever in India. It is notably during the soldier's first year or two of service in that country that his risk of contracting it is so great. It seems to us that something in the shape of a public health department, with local boards at different military centres, might be organised. On the occurrence of any outbreak the fact should be reported to the nearest local committee or board, who should proceed to investigate all the circumstances on the spot, with the skilled aid of some engineer or officer of the public works accustomed to sanitary work, so that any defects might be traced and remedied without unnecessary delay. The time has surely come for a thorough and systematic inquiry into the causes of typhoid fever in India by medical, sanitary and engineering experts and for some method of procedure being organised and carried out for investigating local outbreaks and adopting some practical action in regard to them.

## THE DEARTH OF DOCTORS IN INDIA.

The *Civil and Military Gazette*, in advertising to the prevailing unhealthiness of North-Western India, considers the time opportune for reiterating its complaints against the inadequate supply of doctors. The medical services in India have no representation commensurate with their

importance in the government of India, and it is to this that our contemporary attributes the fact that their complaints are not attended to. It is not, however, from the point of view of the doctors that the question has to be regarded. It is obviously a public question and a serious one as far as their actual and prospective patients are concerned, for a scarcity of medical aid during unhealthy seasons becomes a serious affair for the public. There does not appear to be a sufficiency of medical officers for ordinary work, to say nothing of any margin for contingencies. Owing to the paucity of medical officers, too, it is alleged that there are great difficulties in getting leave. Economy is no doubt a commendable quality in a Government, but there is such a thing as cutting down below the line of safety, a point which, according to our contemporary, seems to have been reached by the Indian Government.

## PESHAWAR DISTRICT.

It is stated that the administrative medical charge of the Peshawar district will be held alternately by a Brigade-Surgeon-Lieutenant-Colonel of the Medical Staff and of the Indian Medical Service and that the Quetta district will be a Surgeon-Colonel's charge.

## FIELD HOSPITALS IN BURMA.

It appears that the mobilisation of the field hospitals in Burma is exercising the minds of the authorities of the Madras Government. The hospitals are in Rangoon and supposed to be in readiness to accompany troops proceeding on active service, but they could not, in reality, be mobilised under a month, owing to their not being fully equipped and furnished with the requisite *personnel*. To draw the *personnel* from the permanent hospitals of the district would be to unduly denude these institutions, and to maintain a reserve of medical officers in readiness at Rangoon would be too costly a proceeding for the Government to entertain—hence the difficulty.

Yet another remedy for snake-bite, this time a vegetable one, has been seriously discussed. Brigade-Surgeon W. Dymock has contributed a paper dealing with this specific to the most recent number of the *Journal of the Bombay Natural History Society*. The plant in question is scientifically known as *Pogostemon Parviflorus* and its uses in cases of snake-bite are said to have been long well-known to natives in the western parts of India. Mr. Dymock seems to have procured good evidence as to its value in cases of bite by the venomous *Echis Carinata*.

Cholera of a severe type is still prevalent in Kulu, so it is extremely unlikely that the Viceroy will visit the Valley during the rains.

Dr. Deare, Civil Surgeon of Damoh, has succumbed to the injuries lately inflicted on him by a wounded tiger.

## INDIAN MEDICAL SERVICE.

*Bengal*.—The Queen has approved of the following promotions:—Surgeon-Majors to be Surgeon-Lieutenant-Colonels (dated March 30th, 1892): Alexander Crombie, M.D.; William Reed Murphy, D.S.O.; Chas. Henry Joubert; Edgar Geer Russell; John Scully; Geoffrey Craythorne Hall; Adam Scott Reid; William Andrew Durnford Fasken, M.D.; Edward Lawrie; Joseph Wilson, M.D.; Edward Mulvaney; John Manook Zorab; Russick Lall Dutt, M.D.; John Thos. Brownrigg Bookey; Alexander McGregor; James Young; Joshua Duke; John McConaghey, M.D.; Edward Palmer; Alfred Henry Williams; Robert Andrew King Holmes, M.D.; John Edward Charnock Ferris. Surgeon-Captains to be Surgeon-Majors (dated March 31st, 1892): Charles Pardey Lukis; Robert Richard Harvey Whitwell; Lawrence Austine Waddell; George Shewan Dhanjibhai Barjoעי Spencer; James Clarke, M.D.; Cooverjee Cawas jee Vaid; Philip Durrell Pank; Thomas Richard Mulroney, M.D.; Thomas Rankin Macdonald.

*Madras*.—Surgeon-Majors to be Surgeon-Lieutenant-Colonels (dated March 30th, 1892): Arthur Mudge Branfoot; William Edward Johnson, M.D.; Stanley Locker Dobie; George Frederick Bevan; Andrew Francis Dobson; Charles Little, M.D.; Thomas Mayne. Surgeon-Captains to be Surgeon-Majors (dated March 31st, 1892): Donald Frederick Dymott; Rustom Hormosji Cama; Winthrop Benjamin Browning; Cecil Henderson; Framji Ruttopji Divecha; Crossaile Miller Thompson; Cubitt Sindall Rundle; James William Evans; Brigade-Surgeon-Lieutenant-Colonel Lewis Charles Nanney (dated May 23rd, 1892).

*Bombay*.—Surgeon-Captains to be Surgeon-Majors (dated March 31st, 1892): Henry Peers Dimmock and Charles

Bradley Maitland; Brigade-Surgeon-Lieutenant-Colonel Isidore Bernadotte Lyon, C.I.E. (dated April 2nd, 1892).

**MILITIA MEDICAL STAFF.**—Surgeon-Lieutenant-Colonel M. Moore, 4th Battalion, Princess Victoria's (Royal Irish Fusiliers) resigns his commission; also is permitted to retain his rank and to wear the prescribed uniform on his retirement (dated June 25th, 1892).

**NAVAL MEDICAL SERVICE.**—With reference to the notice in the *London Gazette* of June 21st, 1892, the surname of Fleet Surgeon Henry Scott Lauder, placed on the Retired List, with permission to assume the rank of Deputy-Inspector-General of Hospitals and Fleets, is here correctly given and not as therein stated.

**VOLUNTEER CORPS.**—*Artillery*: 1st Sussex (Eastern Division, Royal Artillery): Surgeon-Captain W. S. Burrows to be Surgeon-Major (dated June 25th, 1892).—1st Cornwall (Duke of Cornwall's) (Western Division, Royal Artillery): Surgeon-Lieutenant R. T. Thomas, M.D., resigns his commission (dated June 25th, 1892).—*Rifle*: William Duncan Fraser, M.B., to be Surgeon-Lieutenant (dated June 25th, 1892).—1st (Inverness-shire Highland) Volunteer Battalion, the Queen's Own Cameron Highlanders: Walter de Watteville, M.B., to be Surgeon-Lieutenant (dated June 25th, 1892).—4th Volunteer Battalion, the Devonshire Regiment: Charles Edmund Russel Rendle, Gent., to be Surgeon-Lieutenant.

## Correspondence.

"Audi alteram partem."

### "ASPIRATION IN PNEUMOTHORAX."

To the Editors of THE LANCET.

SIRS,—The paper by Dr. Sutherland in your last number (just come under my notice) suggests a very few remarks which, though very hurriedly written, I hope you may be able to insert, as the subject is one of importance. Perhaps the most successful case on record of paracentesis in pneumothorax is one which I published in 1865 and to which I can only now thus briefly refer Dr. Sutherland in the *Glasgow Medical Journal* for the above date, p. 165. In that case the patient was beyond doubt *in extremis* from suffocation and collapse, having been brought into the Royal Infirmary of Edinburgh by the police as a dying woman. It was before the days of aspiration becoming usual in this country, but not before I myself had been taught to aspirate by the late Dr. Bowditch of Boston, whose operations preceded those of Dieulafoy by twenty years or more. The chest in this case was punctured twice at an interval of a few days and each time with marked relief, but aspiration was not employed and according to my present judgment would not have been beneficial. The object in view was not at all to remove the whole or the greater part of the air, but only such amount as would come away through a very small-bore cannula, which was left *in situ* after insertion for two hours, so as to allow of the disturbed mechanical balance being readjusted. The air came away at first in such a blast as to blow out a taper over and over again; but after two such operations nature did the rest and so perfectly that there was no appreciable fluid effusion and the patient recovered. I think Dr. Sutherland will do still better in his next case *not* to aspirate, but to give time for the excess of air to come away. He says that on his first puncturing in his case "no air passed out." How did he ascertain this? It is easy to see that, when the aspirator was attached, "air was at once heard to pass into the bottle"; but my inference would be that if it would pass into the bottle thus it would also pass out without the aspirator to such an extent as was needful to relieve pressure. More than this should not, I think, be attempted, on the grounds so well put by Drs. Wilson Fox and Hilton Fagge.

I am, Sirs, yours truly,

Glasgow, June 20th, 1892.

W. T. GAIRDNER.

To the Editors of THE LANCET.

SIRS,—In Dr. Sutherland's interesting and able account of a case of pneumothorax successfully treated by aspiration I note the following remark:—"In considering the question of aspiration one point must not be lost sight of—namely, that an

attack of pneumothorax, by giving rest to the affected lung, may be a most effective therapeutic agent in phthisis." I am aware that this view is held by many and I believe that on similar principles some hold that pleuritic effusions in tubercular subjects are best left alone. In other words, the idea seems to be that a lung when collapsed either from the presence of air or fluid in the pleural cavity is in a condition of physiological rest, and is therefore better able to resist the inroad of tubercle than if it were working normally. I cannot help thinking that to regard a collapsed lung as an organ in a state of physiological rest and to consider collapse of a lung as in any way able to check the progress of phthisis is incorrect. When we speak of giving rest to an inflamed joint we mean absolute and complete immobility, and this is not incompatible with restoration of function. But is this so with the lung? The lungs take their rest between the acts of respiration, as does the heart between its beats. At no time does the physiological rest of the lungs amount to the condition of collapse. This physiological rest we attempt to secure by keeping the patient in bed, freeing him from excitement, quieting his circulation and reducing his temperature. I cannot see that we are justified in going further and depriving him, or allowing him to be deprived, of the use of his lung altogether. It seems little less than absurd to argue that a patient is better off without any working lung at all than he is with only a portion of it *hors de combat*. How is collapse of the lung supposed to check the spread of phthisis? Hilton Fagge says that the consequent anæmia of the part has this effect, but I have never yet seen a collapsed lung anæmic; on the contrary, I have always found it extremely vascular and congested with non-aerated blood. The circulation is doubtless less active in the collapsed than in the normal lung, but this would tend to confine the bacilli to the precincts of the collapsed part rather than to spread them into the general circulation, where we might hope they would find less comfortable quarters. What is the evidence on which it is thought that pneumothorax produces a beneficial effect on the progress of phthisis? It cannot be statistical, for the death-rate of pneumothorax in phthisis is from 50 to 90 per cent. It merely rests on the facts that in a few cases of recovery after pneumothorax the tubercular process has seemed quiescent, and that in some fatal cases the collapsed part of the lung has been the only portion found free from tubercle. But in the former cases we have no proof that the tuberculosis was not quiescent at the time of onset of pneumothorax, for pneumothorax is a pure accident and by no means an indication that the tubercular process is active at the time of its occurrence, whilst in the latter it is at all events probable that the collapse after pneumothorax of the only working portion of the lung was the actual cause of death.

In conclusion, I cordially agree with Dr. Sutherland that the best treatment in his case was the one which he adopted, and even at the risk of reopening a fistula I would do all in my power to favour re-expansion of a collapsed lung, whether the collapse be due to air, fluid, or both, in the pleural cavity.

I am, Sirs, yours obediently,

LEONARD G. GUTHRIE.

Upper George-street, W., June 27th, 1892.

### "EX-CATHEDRA UTTERANCES v. SCIENTIFIC CAUTION."

To the Editors of THE LANCET.

SIRS,—In deprecating the admission of medical controversial matter into the lay press, THE LANCET of May 7th, 1892, uses the following remarkable phrase:—"The writer regrets that scientific questions are not handled in the way in which men discuss them who 'have acquired the spirit of caution which illumines the *savant*, but darkens the counsels of the ignorant!'" How a spirit of caution can illumine one person and darken another is a problem not in my power to solve. The reason for this profound remark is a letter signed by one "Buggobutty Bose," which appeared in the *Bombay Gazette*. For all we know—or for that matter THE LANCET knows—to the contrary, Mr. B. B. may be a medical man; but however that be, his statement that to continue to employ a system which has been proved to be unsafe is criminal does not to my mind display ignorance. The point at issue is: Which of the two systems of administering chloroform shall be adopted, the Edinburgh or the London system? Is the respiration to be watched or the pulse? Mr. B. B. says that the Hyderabad Commission has proved that to "take the pulse as a guide to the effect of chloroform is unsafe." If it is

unsafe it would be criminal to use it. What is it precisely that the Hyderabad Commission has proved? It has proved conclusively that as long as chloroform is given in a diluted form, with perfectly regular respiration and is not pushed after anaesthesia has set in, there is no possibility of the heart being affected. When the heart is affected it is by interference with the breathing or by an overdose, whether directly or indirectly need not at present matter. Therefore to take the pulse as a guide for the effect of chloroform is to watch for results which, under proper administration, cannot occur and when they do occur are proofs that there has been maladministration. Without entering into the argument as to whether the respiration or the heart stops first, the Hyderabad Commission has proved that if the above conditions are fulfilled *and the breathing remains regular* there can be no possible danger. To watch the breathing, therefore, is the only safe way to ensure that condition in the patient which is absolutely essential and necessary for his safety. As soon as the pulse gives a signal of danger I maintain that safe limits have been overstepped and one or perhaps all the rules laid down by the Hyderabad Commission have been broken. Let anyone show me a single case in which these rules having been strictly followed the pulse has shown a sign of danger. This is the point between me and my opponents and until they can prove this no amount of assertion will avail. Under the London system of chloroform administration deaths are constantly occurring, whereas we can show a clean record without a single death during forty-five years. This is a plain hard fact which no argument can get over, and if Mr. B. B. understands that to follow a method under which deaths occur and to neglect a method which is free from deaths and danger is criminal, he is a person of sound common sense, whether he is a layman or a professional. The writer in THE LANCET says that the practice of the London anaesthetists has been more than once put before the profession in its columns and he again repeats that their system is to watch the respiration *as well as* the pulse. Our system is to watch the respiration only and the difference is irreconcilable. If we watched the pulse we should stultify ourselves by looking for effects which cannot be produced unless the patient's breathing has been obstructed or he has been poisoned by an overdose. We have had no deaths because we have no overdoses, and it is by watching the respiration only and never allowing the patient to inhale anything but air when it is irregular that we prevent their possibility. There is no necessity on this occasion to discuss the manner in which the overdose takes effect, whether by respiratory narcosis or by cardiac syncope. All we contend is, administer according to our system and there will be no such thing as an overdose. Mr. B. B. advances no "charge of wholesale crime against the bulk of the profession," as the writer in THE LANCET says. But until these facts are controverted I agree with him that in future it will be criminal to watch the pulse. Nor is it the large bulk of the profession that follows the unsafe and dangerous system. It is, as THE LANCET shows, the London anaesthetists who "consistently" do so. Unfortunately, they are the teachers of the English schools and consequently the evil is widespread and will be difficult to eradicate.

I am, Sirs, yours obediently,

EDWARD LAWRIE,  
Surgeon-Lieutenant-Colonel.

May 29th, 1892.

\* \* Surgeon-Lieutenant-Colonel Lawrie's remarks upon our annotation are simply a reiteration of his views. Some experimenters refuse to admit his results and English chloroformists naturally decline to accept his statements that they do not know how to give chloroform. Deaths, moreover, have occurred both in Scotland and England when Syme's rules have been faithfully followed. We can therefore only repeat that at present it behaves all concerned in this controversy to adhere strictly to the methods of science and avoid *ex-cathedra* statements or arguments based on premises which are themselves at present *sub judice*.—ED. L.

## THE MEDICAL PROFESSION IN PARLIAMENT.

To the Editors of THE LANCET.

SIRS,—In your first leading article of to-day's issue you refer to the politics of the immortal Sydenham in such a way as to

give the impression that Sydenham as a physician took part in politics; you include him in the list with Harvey, Arbuthnot and Meade. As everything connected with Sydenham is of deep interest you will forgive me for saying that there is no evidence that Sydenham the physician was even remotely connected with politics. Prior to meeting Dr. Thomas Cox he was, like his brothers William and Francis, a very pronounced Parliamentarian and like them took up arms for "the House and the Wood." But the fight for liberty practically ended with the surrender of Charles I. in 1646, fifteen months after which he was beheaded. Sydenham took his M.B. in 1648 and he was not admitted to the licence of the College of Physicians until June 25th, 1663, from which time, until his death in 1689, his name does not occur in politics. He was, unlike Willis or Harvey, who were both politicians and physicians, like his friends Havers and Glisson—when he put his hand to the plough he did not look back. His character is summed up in the quotation he selected for his "Medical Observations": "Whatsoever thy hand findeth to do, do it with all thy might; for there is no work, nor device, nor knowledge, nor wisdom in the grave, whither thou goest." In medicine Sydenham found a soul-satisfying study and to-day the civilised world benefits by his undivided love for the profession he adopted and adorned.

I am, Sirs, yours truly,

GEORGE FOY, F.R.C.S.I.

June 25th, 1892.

\* \* Mr. Foy has misread our article. That Sydenham took an active personal part in politics after he had become an eminent consultant we never asserted. That he was an example of Coleridge's remark that every man is born a Parliamentarian or a Royalist we did assert and we still maintain. His was essentially an innovating and reforming mind, not more so when he served as an officer with the forces of the Parliament than when, in his fortieth year, he, as "an innovator and something of a plain dealer," denounced to Mapletoft those "qui vitio statim vertunt si quis novi aliquid in medium proferat." His whole mental attitude and inclination was liberal, in perennial conflict with official conservatism and tradition, professional or lay. To deny this is to misunderstand Sydenham—the Sydenham of John Locke's noble elegiacs, the Sydenham of every biographer of him, from Dr. Samuel Johnson to Dr. John Brown. Mr. Foy will find an even more trenchant opinion than ours as to Sydenham's bias in politics in the appendix to the late Dr. King Chambers's Harveian oration (author's edition). That in Parliament he would have sat opposite to William Harvey who can doubt? We never hinted that "Sydenham the physician took part in politics." Our whole contention was that the political career should be reserved for those of the profession who had graduated without intention to practise, or who were in the position of emeritus practitioners, retaining full possession of their powers and willing to devote their experience and their leisure to the good of the body politic.—ED. L.

## "THE VACCINATION EGG."

To the Editors of THE LANCET.

SIRS,—The confirmation of Jenner's observations as a naturalist, which formed the subject of your leading article last week, is the latest, but it is not the one that is best known. Another confirmation made in 1871 was published in *Nature* (vol. v., p. 382), which is even more interesting as bearing out Jenner's original account in its most distinctive and most minute points and as having served to convince Darwin, who introduced a paragraph into his latest revision of the "Origin of Species," calling it "a trustworthy account of a young cuckoo, which was actually seen, whilst still blind and not able even to hold up its own head, in the act of ejecting its foster-brothers." To show how closely Mrs. Blackburn's account agrees with that of Jenner I have written a few sentences from each in parallel columns. The original observations were made near Berkeley on June 18th, 1787; the confirming observations in Argylshire in June, 1871. In the former case a hedge sparrow's nest contained when first seen two of the bird's own eggs with one cuckoo's egg, and next day the newly hatched cuckoo and one newly-hatched hedge sparrow; in the latter case a meadow pipit's:

nest when first seen had two partly fledged pipits with one cuckoo's egg and next day the newly hatched cuckoo only, the two young pipits, which were several days old and open-eyed, having been found lying on the bank at a distance of ten inches from the nest. They were put back, being still alive, and then ensued the events which are related in the right-hand column:—

Jenner's account, "Phil. Trans.," 1788, p. 225.

"The mode of accomplishing this was curious: the little animal, with the assistance of its rump and wings, contrived to get the bird upon its back and making a lodgment for the burden by elevating its elbows clambered backward with it up the side of the nest till it reached the top, where, resting for a moment, it threw off its load with a jerk and quite disengaged it from the nest.

"It remained in this situation a short time, feeling about with the extremities of its wing, as if to be convinced whether the business were properly executed and then dropped into the nest again."

Dr. Norman Moore, in his Life of Jenner in the "Dictionary of National Biography," has called attention to the fact that the well-known naturalist Waterton, the author of "Wanderings in South America" and "Essays on Natural History" (both edited by Dr. Moore, with an excellent biography of the author), had rejected Jenner's narrative as incredible. "The young cuckoo," wrote Waterton, cannot by any means support its own weight during the first day of its existence. Of course, then, it is utterly incapable of clambering rump foremost up the steep side of a hedge sparrow's nest with the additional weight of a young hedge sparrow on its back. The account carries its own condemnation, no matter by whom related or by whom received." It is singular that Waterton, who was well known to be a strict Roman Catholic, should have actually used Hume's famous argument on miracles in order to discredit a fact in natural history which was generally accepted by naturalists at the time of his writing (1836). It is more probable, he implies, that the witnesses should have been deceived than that the events should actually have taken place. But he would not have argued so concerning the events which Hume thought incredible, nor even concerning ecclesiastical miracles of much more recent date. Dr. Norman Moore, as in private duty bound, backs up Waterton and calls Jenner's narrative of the young cuckoo an absurdity. He has also found a passage in Baron's "Life of Jenner" which leads him to think that the merit (or demerit) of the observations really belongs to Henry Jenner, then a lad, who was set to watch the cuckoo's nest and to report to his uncle. Baron's statement (vol. i., pp. 85, 86) is no doubt to that effect; but why should we assume with Dr. Norman Moore that Henry Jenner "gave an imaginary account"? Why should not a lad be a competent witness? Darwin was at length satisfied with the testimony of a lady, a talented artist. The testimony of the gentleman at Otlands in 1886 was in your opinion strengthened by that of his sister and of another lady. Nor is it certain that Jenner was dependent to the extent that Baron implies on the reports brought to him by his nephew? For in relating the successive steps of the ejection in his letter to the Royal Society he uses four times the expression, "I saw," or its equivalent.—I enclose my card and I am, Sirs, your obedient servant,

June 27th, 1892.

M. N. O.

## BOVINE TUBERCULOSIS.

To the Editors of THE LANCET.

SIRS,—With reference to your article upon the probability of bovine tuberculosis being transmitted to man through

eating the flesh or by drinking the milk &c. of such diseased animals, I desire to point out to you the fact that at least one-third of the Kaffir diet in Africa consists of sweet and sour milk, that the flesh of cattle dying of all sorts of diseases—including those dying of tuberculosis—is devoured both in a well cooked as well as in a half raw state by the natives; yet phthisis is a rare disease amongst either the adult or infantile native population; indeed, from a long intimate association with the natives of South Africa I have never met with any cases of disease traceable to the circumstance you so alarmingly describe as daily happening in the British Isles. That phthisis does exist amongst the bovines of South Africa is tolerably well known by those who have studied the subject. It will also be borne in mind by you that the "raw" native uses little clothing, but plenty of red clay, lives in ill-ventilated huts and when not in them (the huts) spends most of his daily life in the open. I am, Sirs, yours obediently,

Herschel, South Africa.

S. CARTWRIGHT-REED, M.D.

## THE FRENCH WORKMEN'S SANITARY CONGRESS.

(FROM OUR SPECIAL CORRESPONDENT.)

It is now definitely decided that the French Workmen's Congress of Hygiene will meet on July 3rd and terminate its labours on July 10th. We have already described the nature and origin of this Congress. It is organised by the Possibilist Party, the most influential of the various factions in which the Labour Party of France is divided. This party has determined that it will try and effect some immediate improvement in the condition of the working classes and for once leave abstract theories of social justice aside, so as to secure for the living generation practical advantages. No legislative or political question offered a better field for such action than the broad issues raised by sanitary reformers. It has already been explained that the Sanitary Workmen's Congress was to be preceded by a series of six lectures and we described the first of these lectures delivered by Dr. Dujardin-Beaumetz on Food. The five other lectures have also been delivered and proved most successful. They were each attended by more than a thousand workmen, all representative men, who listened with such rapt attention and showed such enthusiastic appreciation of what was taught by the eminent lecturers that some of the lectures were prolonged for more than two hours. What is more remarkable is the fact that the more scientific the lecture became the more it was appreciated. When dealing with more purely workmen's questions, such as factory legislation, the attention was not so marked, but it became intense when the lecturers described the chemistry of food, the circumstances that affected the quality of mothers' milk and the vital statistics that demonstrated the fatal consequences of bad sanitation. These lectures are being published in the cheapest form, so as to be accessible to the working classes and the most scientific lectures command the best sale. This is a fact well worth noting, for it shows the determination of the more intelligent working men to acquire a scientific basis for their opinions. A large number of the workmen who attended these lectures have also visited the municipal laboratory, where methods of detecting the adulteration of food were shown. The question of adulteration proved very interesting and fraudulent practices in providing alimentary supplies would be suppressed with no light hand if the working classes alone had to decide such questions. The disinfecting station, the sewers, the sewage farm and other places of interest as bearing on public health have been visited by hundreds of workmen during the last few weeks. They were always accompanied by engineers or others who could give full explanations.

Now that the period of instruction is nearly completed, the workmen who have followed these lectures and these investigations are discussing in their respective societies how the knowledge they have acquired can be practically applied. The various trades unions and other workmen's societies belonging to the Possibilist Party are busy drawing up reports and proposals which they will present at the forthcoming Congress. A Commission on each subject will be appointed to study these reports and proposals, take the best points out of them and combine them all in one single report and one set of resolutions. Then discussions will follow and

we shall see to what extent the labour organisations of Paris have profited by the lessons they have had and how they propose to deal with those sanitary problems which in France at least have in the main been discussed only by experts. Apparently the workmen are well satisfied with what scientific men have told them. They do not wish to go any further; they accept what they have been taught, they only demand that the moral of the lesson should be enforced by suitable legislative enactments. The approach of this original style of congress—for I am not aware that in any country workmen have held a sanitary congress—has attracted a great deal of public attention. The French press has given it wide publicity and in the country several municipalities have decided to encourage this effort. The Municipalities of Lilles, Blois, Angers, Tours and Châtelleraul have voted subventions to enable the workmen of these towns to send delegates to the Congress. From abroad also expressions of sympathy and interest have been received. Though the Congress is a purely national gathering, foreign representatives will be welcomed with great cordiality as honoured guests. There is no doubt that a large number of trade unionists would be present but for the general elections which will take place in England just at the time the Congress will meet in Paris.

Paris, June 28th.

## NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

### Notification of Infectious Diseases.

A CASE was heard last week before the Tynemouth Petty Sessions which shows how careful practitioners should be not to place themselves in a false position by inattention to the requirements of the Infectious Diseases Notification Act. The defendant (a qualified man) was summoned at the instance of the Tynemouth Rural Sanitary Authority for not sending to the medical officer of health of the district a certificate notifying that a child was suffering from typhoid fever. The defence was that the child was not suffering from typhoid fever and that if it was the fever was over when the practitioner was called in. The magistrates, however, decided from the evidence that the case was one of typhoid fever and therefore inflicted a fine of 20s. and costs, the latter, it is said, amounting to three guineas. The father of the child was also summoned for not reporting the case, but, pleading ignorance of the law, got off by paying costs.

### Typhoid Fever at Northallerton.

There is said to be an alarming epidemic of typhoid fever at Northallerton and it has been decided to ask the Local Government Board to hold an inquiry into the cause of the outbreak as soon as possible. The worst of these inquiries is that it is generally so long before the reports come out that they are of little or no use in the way of affecting an epidemic, but the people of Northallerton should in the meantime bestir themselves to get at and remove the cause.

### Carlisle.

The outbreak of typhus fever which caused such alarm a few weeks ago is not yet stamped out, a fresh case being reported, a female, who had been in almost daily contact with other cases. The medical officer of health has recommended that the period of convalescence should be extended to that usually recognised as necessary—namely, four weeks—some of the patients having been discharged after a little over three weeks, which he considered too short and unsafe. As to the water-supply of Carlisle, an informal examination has been made of the water of the upper reaches of the Caldew, which was found to be pure and free from organic contamination and a favourable impression was made as well as to the quantity which could be obtained, for practically there is no limit to the storage capacity of the watershed when the country above Mosedale and Skiddaw Forest is taken into account. The water will, however, have to be carefully examined and tested as to its action on lead.

### Small-pox on Tees-side.

Dr. Malcomson, the medical officer of health for Middlesbrough, has reported five cases of small-pox since its last meeting to the committee of the Middlesbrough Fever Hospital, one of which was the fatal case of the Spanish seaman previously noted and of the others three were from Stockton; these were all from one house, were very bad cases, and were all unvaccinated. The fourth case was that of a shop-

man who had probably contracted the disease in the course of his business.

### Darlington: Curious Meteoric Phenomena.

At the last meeting of the Darlington Naturalists' Field Club some fragments of stone were exhibited which were observed to fall in numbers on the flags of the High-row, one of the principal thoroughfares of the town, during one of the late severe thunderstorms. The fragments were the size of a horsebean and presented some evidence of having been fused. The *Northern Echo* says they were handed over to Mr. Stock, F.C.S., county analyst, for examination.

### A Medical Missionary Society for Newcastle.

It is proposed to form a medical missionary society for Newcastle and a circular has been issued to the profession calling a meeting for next Thursday at the College, at which Professor Philipson is announced to preside and Dr. Henry Martyn Clark, who has had considerable experience in medical missionary work in the Punjab, will give an address.

### Match-poisoning at South Shields.

A case of poisoning by phosphorus is reported from South Shields. A married woman, having steeped some lucifer matches, drank the infusion and then told her husband. Medical aid was at once sought and the stomach-pump was used—it is hoped with effect—but she is still in a precarious state.

### The Tyne and Norway.

We have now steamers running every day to and from Norway, making the North Sea a regular ferry. The fine Atlantic steamer the *City of Richmond* goes on regular fortnightly cruises. Last week she went off from the Tyne with her full complement of 260 cabin passengers. On Saturday a very large party of Americans arrived in Newcastle, en route to Norway. I mention this in case any of your readers are thinking of crossing from the Tyne, that they may make their arrangements in good time to save disappointment, as the Tyne is a favourite route. It is calculated that 20,000 persons crossed last year and this year I hear that the number is likely to be even more.

The guardians of the Easington Union, county Durham, have decided to build a new infirmary at the workhouse forthwith. The cost of its erection will be about £5000.

The committee of the Gateshead Children's Hospital have received a further gift of £250 from the executors of the late Mr. J. Glenton, of this city.

Newcastle-on-Tyne, June 29th.

## SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

### Edinburgh Medico-Chirurgical Society.

A SPECIAL meeting of this Society was held last week and was devoted to a discussion on pernicious anæmia, introduced by a long paper by Dr. Brakenridge on the treatment of the disease by the transfusion of human blood. The results recorded were very striking and extended over a period of about seven years. Dr. Affleck also gave notes of a case he had treated in this way with remarkable success. A long discussion followed in which the pathology and treatment of different forms of anæmia were considered and also the best method of performing transfusion and the precautions to be used. The paper and the discussion which it evoked will probably determine a new departure in the treatment of the hitherto incurable cases of the disease.

### The Edinburgh Water-supply.

The committee of the Edinburgh and District Water Trust appointed to consider the report of the engineers upon the water-supply of the city have, it is understood, drawn up the following recommendations: (1) that the Deacon metre should be more largely used to check waste; (2) that the Trust should have power to regulate the water fittings; (3) that application should be made to Parliament for a Bill for the introduction of a new supply.

### The Volo Plague in Scotland.

The committee appointed by the Board of Agriculture to investigate this matter has had one or two meetings. At one of these Professor MacFadyean said he thought the plan of Loeffler feasible and it would be well that an application should be made to him for the means of making the experi-

ment. It will be remembered that Loeffler's method of destroying the animals is by contaminating their food with an organism which is specially fatal to them and not to other mammals.

#### *The Health of Edinburgh.*

The mortality last week was 82, making the death-rate 16 per 1000. Diseases of the chest accounted for 30 deaths and zymotic diseases for 7. The intimations for the week were—typhoid fever 12, diphtheria 2, scarlet fever 35, and measles 67. June 28th.

## IRELAND.

(FROM OUR OWN CORRESPONDENT.)

### *University of Dublin.*

COL. LOWRY is a candidate for the representation of the University at the general election. In his address to the electors when referring to the medical graduates, who form a considerable portion of the constituency, he states that the medical profession has a special claim upon the representatives of the University, for unlike the legal profession very few of its members have seats in the House of Commons. The dispensary medical officers in Ireland he acknowledges have long had reason to complain of their position in regard to both their duties and their pensions, and he promises if elected to give his special attention to the interests of this large and important body. Mr. Carson, Q.C., his opponent, takes somewhat similar views as regards the grievances of dispensary medical officers.

### *Parliamentary Medical Representation.*

The question of parliamentary medical representation has engaged the attention of the Council of the Irish Medical Association and at a special meeting held last week to consider the matter, the following resolutions were unanimously adopted:—"That the Council of the Irish Medical Association having considered the question of special parliamentary representation for Irish Poor-law medical officers, and having had the advantage of hearing the views of the deputation which attended from the Irish Parliamentary Representation Committee, hereby approves the action of that committee, and cordially recommends the movement to the members of the association and the medical profession in Ireland. That the Irish Parliamentary Representation Committee be requested to keep this Association informed as to its proceedings. That the Executive Committee of the Irish Medical Association be instructed to make immediate inquiry from each parliamentary candidate as to his views on the redress of Poor-law medical officers' grievances."

Mr. Kenny, M.P., coroner for the city of Dublin, will be a candidate for one of the Dublin divisions at the coming election.

### *County Galway Census.*

The population of the County Galway has decreased since the last decade by 11.5 per cent. The number of persons receiving Poor-law relief has increased from 1 in 60 to 1 in every 52 of the population. The births registered during the ten years amounted to 50,347, a number equal to 22.0 per 1000; the average rate for the whole of Ireland being 23.2. The deaths were 31,998, equal to 14.0; the rate for the entire country being 17.8.

### *The late Dr. Robert McDonnell, F.R.S.*

A bust of this eminent surgeon, by Mr. Bruce Joy, the well-known sculptor, will be unveiled at the Royal College of Surgeons during the Tercentenary of Trinity College. June 28th.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

### *Extirpation of the Liver in Frogs.*

THE removal of the liver does not in the frog involve an immediately fatal issue, as is the case in mammals. The duration of the survival is, however, a question upon which physiologists differ, Müller maintaining that death supervenes in three or four days, whilst Moleschott states that the liverless frog does not succumb until as many weeks have elapsed. M. Roger has investigated this point and finds that of two frogs deprived of their livers one which is placed in a vessel containing water which is not renewed dies in three or four

days, whilst the other, which is kept in water maintained at a uniform temperature and which is constantly renewed, lives for a period varying from eight to fourteen or even twenty days. The explanation is easy. The functions of the liver being suppressed, extra work is thrown on the kidneys to eliminate the products of metamorphosis. When the animal is placed in stagnant water these excreted products are reabsorbed and the frog dies poisoned sooner than is the case with the frog kept in a running stream.

### *Death of the Inventor of the Hypodermic Syringe.*

The ordinary hypodermic syringe is known in France as the "seringue de Pravaz," the instrument having been invented by Dr. Pravaz of Lyons. The death of this gentleman is announced in this week's journals. He was the director of an orthopædic establishment in the silk capital and was well known as a *médecin orthopédiste*. In England the practice of hypodermic medication is generally associated with the name of Dr. Alexander Wood of Edinburgh.

### *Therapeutics of Typhoid Fever in the Paris Hospitals.*

There exists in Paris, as in London and other medical centres, much divergence of opinion as to the efficacy of cold baths in the treatment of enteric fever. This method is attributed in this country to Brand of Stettin, although it had been advocated nearly a century ago by our own countryman, Currie. Dr. Jubel-Rénoy has just communicated to the Société Médicale des Hôpitaux the result of an inquiry he has conducted into this question. For this purpose he applied to eighty colleagues, forty of whom replied. Of these hospital physicians fourteen disapprove of the systematic employment of the cold bath. Twelve, on the contrary, are enthusiastic believers in the method which they apply indiscriminately to all cases, whether they be light or severe in character. Two believe in tepid baths gradually cooled down and eight, while approving generally of cold baths, impose certain restrictions. Of 175 cases treated by the adversaries of the method, 25 died, giving a mortality of 14.2 per cent. Thirty-nine cases treated by the method, with restrictions, yielded one death, or 2.56 per cent. In Professor Bouchard's wards, where progressively cooled tepid baths are in fashion, 54 out of 554 cases died, or 9.74 per cent. The advocates of systematic cold baths lost 40 out of 492 cases, or 8.13 per cent. M. Jubel-Rénoy concluded his paper by expressing his opinion that the introduction of balneotherapy into typhoid fever wards had been the means of reducing the mortality from that disease at least 5 per cent.

Paris, June 20th.

## BERLIN.

(FROM OUR OWN CORRESPONDENT.)

### *The Twenty-first Surgical Congress.*

AT the last sitting of the Surgical Congress, Professor Julius Wolf of Berlin showed a man whose larynx had been completely extirpated and replaced by an artificial one made by the mechanician, Oehmke. The man spoke so loudly and distinctly that he was heard in all parts of the hall. He can even sing a little. The artificial larynx gives him little inconvenience and he can easily change it at will. Schmidt of Cuxhaven spoke on the total extirpation of the popliteal aneurysm and on a congenital bending of the cartilage of the epiglottis. Professor Olshausen of Berlin discussed the total extirpation of the uterus for cancer and showed about forty preparations. He maintained that this operation ought to be much more frequently performed than it is. His opinion is based on experience of many hundreds of cases. Several members, including Thiem of Kottbus, expressed their agreement with him. Förk of Vienna, Braun of Königsberg and Eyselsberg of Vienna spoke on primary sarcoma of the small intestine, Schüller of Berlin on the application of the sculptor's chisel to bones and joints, especially in tuberculous diseases; on chronic rheumatic inflammations of the joints and on cases of osteotomy. Riedel of Jena showed hammers and chisels made of Mannesmann tubes. Thiersch's assistant, Urban of Leipsic, spoke on a new operation successfully performed by Thiersch for compression of the spinal cord by displacement of the bodies of the vertebrae. Under the diseased part a horizontal cut is made to the vertebral column and two cuts on both sides of the column and parallel with it upwards from the ends of the horizontal cut to above the diseased part. From these vertical cuts the column is then chiselled

on both sides, till one can fold the upper half of it, with the skin and muscle-flaps, upwards and thus expose the spinal cord. One then removes the parts of the vertebra which cause the compression and closes the column again. Philipp of Berlin reported his very favourable experience of pental as a narcotic for children, Schede of Hamburg his much less favourable experience of the same narcotic in adults. Schleich of Berlin spoke on local anæsthesia. He has tried to produce anæsthesia by injecting not only cocaine but also other substances into the tissues. He succeeded with chloride of potassium, common salt, sugar and even with distilled water. He resorts to general narcosis only when local anæsthesia proves impracticable or inadequate. Körte of Berlin spoke on the surgical treatment of purulent peritonitis and Lauenstein of Hamburg on agglutinations and omental cords in the abdomen as the cause of very severe colic. The meeting was then closed and three cheers for the chairman were proposed by Esmarck and given by the assembly.

#### *Koch's Tuberculin.*

The preparation and sale of Koch's tuberculin, which have hitherto been in the hands of Dr. Libbertz, will be transferred on the 1st prox. to the great chemical works (formerly Meister, Lucius and Brüning) at Höchst, near Frankfort-on-the-Maine. The fluid will continue to be tested by Dr. Libbertz, who will remove to Frankfort.

#### *New Material for Medical History.*

The well-known Berlin professor of church history, Adolf Harnack, a brother of the professor of medical chemistry at Halle and a son-in-law of the celebrated Leipzig surgeon Thiersch, has collected and published everything connected with the art of healing met with by him in writings bearing on ancient church history. The name of the work, which is dedicated to Thiersch, is "Medizinisches aus der ältesten Kirchengeschichte" ("Medical Matter from the Oldest History of the Church").

#### *New Publications.*

"Cesare Lombroso and the Natural History of Crime," by Dr. Kurella, published in the 147th number of the "Collection of generally intelligible Scientific Lectures," edited by Rudolf Virchow and Wilhelm Wattenbach; "Tone Deafness and Instruction in Music," by Dr. Kunn; "The Progress of Cremation in Germany," by Baron Engerth; the "Successful Treatment of Influenza by Hypnosis," by Dr. Grossmann; "How to kill Bacilli and cure Phthisis," by Ferdinand Koenig of Halberstadt.

#### *Surgeon-General Roth.*

Surgeon-General Dr. Wilhelm Roth died at Dresden on June 13th. He published "Studies of an Army Surgeon" on the camp of Chalons, medical affairs in Belgium, Hanover and England and military medicine at the Paris Exhibition, a "Handbook of Military Hygiene," "Studies on Official and Voluntary Care of the Sick" and the "Elements of Physiological Anatomy for Teachers of Gymnastics." He wrote in periodicals on the English sanitary service in the Abyssinian expedition, the Dutch sanitary service in the war against Atchin, the Russian sanitary service in the Turkish War, military magazines in war and military medical exhibitions and necrological notices of eminent medical men. He was born in 1833, studied in Berlin, graduated in 1855, went to the Frederick William Institute in Berlin as staff surgeon in 1861, was appointed to teach in the Central School for Gymnastics in 1863, promoted to the rank of surgeon-major in 1867 and appointed to teach in the Academy of War. In 1870 he was appointed surgeon-general and corps-surgeon of the Saxon Army Corps.

Berlin, June 28th.

## CANADA.

(FROM OUR OWN CORRESPONDENT.)

#### *Ontario Medical Association.*

THE twelfth annual meeting of the Ontario Medical Association was held in Toronto, June 1st and 2nd, under the presidency of Dr. Richard A. Reeve, Toronto. At the general sessions there was a series of discussions as follows:—  
Obstetrics: The Third Stage of Labour, led by Professor A. H. Wright. Medicine: Diphtheria, A. S. Fraser. Surgery: The Present Status of Antiseptics in Surgery, R. B. Nevitt. Rhinology: Hay Fever, A. B. Welford. Therapeutics: The Therapeutics of Constipation, J. C.

Mitchell. The president of the American Medical Association (Dr. H. O. Marey, Boston) was with us and addressed the Association upon the Anatomy and Surgical Treatment of Hernia. Among the cases presented was one of Landry's Paralysis (Dr. Powell, Toronto), the patient, a man, having regained to a limited degree the power of locomotion. There were over 200 practitioners in attendance at the meetings.

#### *Medical Officers of Militia.*

The surgeons attached to the various militia corps of Canada formed recently an association to be known as "The Association of Medical Officers of the Militia of Canada." Its objects are briefly as follows: (1) The bringing of medical officers in closer relation and the development of a departmental *esprit de corps*; (2) the discussion of matters relating to the medical department of the militia; (3) the discussion of military matters from a medical standpoint; (4) the reading of papers on military medicine, surgery, &c. The first annual meeting was held at the time of the meeting of the Ontario Medical Association, under the presidency of Dr. F. W. Strange. Papers were read by Dr. Warren on Ambulance Work during the Franco-Prussian War and by Dr. Daniel Clark, once Inspector of Surgeons in the United States Army, on Some Brain Wounds, with Results.

#### *Victoria Hospital for Sick Children.*

The Victoria Hospital for Sick Children was formally opened last month by Mr. J. Ross Robertson, president of the board of trustees. This handsome and commodious building has cost £30,000 and is perhaps the most complete of its kind in America. The only thing to be regretted is that there still remains a debt of about £20,000, the existence of which must cripple its usefulness.

#### *Victoria University.*

The last convocation of Victoria University was held last month in Cobourg. Upon the reopening of the College in October next lectures will be given in the new buildings in this city and it will become federated with the University of Toronto, having seven representatives upon the Senate of the latter institution, the charter of the Victoria University not being set aside, but simply held in abeyance during the continuance of federation.

#### *Canadian Qualifications.*

In THE LANCET of April 30th appears a notice of an inquest, at which one T. J. McDonald is quoted as stating he held the degree of M.D., C.M. of the University of Toronto. Such cannot be the case, as the University of Toronto confers only the degrees M.B. and M.D. There does, however, appear upon the roll of graduates of Victoria University the name T. J. McDonald, 1886, M.D., C.M.; but the name does not appear upon the roll of licensed practitioners of the College of Physicians and Surgeons of Ontario, the holding of a University degree in Ontario not being a qualification to practise, the licence of the above-named College being the *sine quâ non*.

## Obituary.

#### SIR WILLIAM AITKEN, M.D., LL.D., F.R.S.

THIS distinguished physician and author, who had long been the subject of renal disorder, succumbed to its effects after some weeks of suffering on the morning of June 25th. The usual indications of uræmia, succeeded by an attack of syncope, were the immediate precursors of the fatal event. Sir Wm. Aitken was the son of a medical practitioner in Dundee, Forfarshire, and was born there on April 23rd, 1825. He was educated in the High School of his native town and on leaving school was apprenticed to his father, at the same time that his friend, now Sir Andrew Clark, Bart., was apprenticed to another practitioner in Dundee. While serving as an apprentice to his father he was a constant attendant in the wards of the Dundee Royal Infirmary. In November, 1842, he matriculated as a student in the University of Edinburgh and after attending classes in the Faculty of Arts and passing through the medical curriculum he graduated as Doctor of Medicine in August, 1848. At the graduation he received a gold medal for a dissertation on a pathological subject. In the same year he became a Licentiate of the Royal College of Surgeons of Edinburgh. In October, 1848, he became associated with the late Dr.

Allen Thomson, professor of anatomy in the University of Glasgow, as Demonstrator of Anatomy and he continued to hold that office, as well as the office of Pathologist to the Royal Infirmary, up to the year 1855.

In the year 1855 Dr. Aitken was appointed by Lord Panmure, then Minister for War, to proceed to the seat of war in the East as "first assistant pathologist" in association with the late Professor R. D. Lyons of the Catholic University, Dublin, to investigate the nature of the diseases from which the troops in the Crimea were suffering and which at the time were filling the hospitals on the Bosphorus with patients. The outcome of these investigations was a valuable report which was presented to Parliament and printed by order in the year 1856. It appeared in the form of a Blue-book of 120 pages bearing the signatures of Drs. Lyons and Aitken, and has since formed an important work of reference on the subject of the diseases which proved so terribly fatal to the British army in the early period of the Crimean War.

In the beginning of the year 1860 Dr. Aitken was selected by the Secretary of State for War, the Right Hon. Sidney Herbert, afterwards Lord Herbert, for the post of professor of pathology in the Army Medical School which was about to be established at Port Pitt, Chatham. The school was opened in October of the same year and from that date until the month of April of the present year he fulfilled the duties of that office. The fast declining state of his health then compelled him to seek leave of absence. This was granted and at the same time it was arranged that he should finally retire from the professorship at the close of the session in July. But, alas, his own end has anticipated this arrangement.

In 1873 Professor Aitken was elected a Fellow of the Royal Society and in August, 1887, the honour of knighthood was conferred on him by the Queen at Osborne on the occasion of Her Majesty's Jubilee. In April, 1888, the University of Edinburgh conferred the degree of LL.D. (*honoris causa*) on Sir Wm. Aitken and in August of the same year the University of Glasgow conferred a similar honour upon him. In the following year his portrait, painted by W. R. Symonds, which had been subscribed for by members of the military medical services, was presented by the subscribers through the Director-General, Sir Thomas Crawford, K.C.B., to the Army Medical Department. It is now on the walls of one of the mess-rooms belonging to the Medical Staff at Netley. An enlarged portrait photograph also exists among the British Museum of Portraits at South Kensington.

As a practical pathologist Sir Wm. Aitken occupied an almost unrivalled position. No one who attended his post-mortem demonstrations prior to the time of his failure in health can forget the admirable precision with which he proceeded, step by step, to unfold to view the anatomical structures and internal organs of the subject before him, to indicate and expound every departure, however minute, from their normal condition and aspect, or the masterly way in which he would connect the pathological changes presented to notice with the previous history and symptoms of the disease which had led to the death of the patient in the case under observation. They were impressive lessons, conveyed through the eye and the ear, which could not readily be forgotten by any of the medical officers who were present at his demonstrations. For some time prior to his decease Sir Wm. Aitken had been engaged in writing a descriptive catalogue of the preparations in the celebrated Pathological Museum belonging to the Army Medical Department, which is now located at Netley. He had completed a first volume, and the fact that the undertaking cannot now be accomplished by one so thoroughly conversant with the museum and its contents and so admirably fitted to describe them is a matter most deeply to be regretted. The break in the work is not merely a misfortune for the Army Medical Service, but is a real loss to the general stock of medical science. Sir Wm. Aitken was a warm-hearted sincere friend, upright and honourable in all his views and dealings and a most loyal colleague. The writer of this brief notice never heard of his having an enemy; his friends seemed to be all who had ever known him.

In conclusion, the titles and dates of some of his numerous publications on pathology and the science of medicine may be briefly mentioned:—1849: "On Inflammatory Effusions into the Substance of the Lungs as modified by Contagious Fevers." 1857: "On the Diseases of the Troops in the East during the Russian War and on the Climate of Scutari on the Bosphorus." 1857: "On the Persistent and Pernicious Influence of the Residence in Bulgaria on the Subsequent

Health of the British Troops in the Crimea." 1857: "On conducting Post-mortem Examinations at Coroners' Inquests." 1857: "Critical and Analytical Review of Recent Works on the Pathology of Vaccination and its Protective Influence from Small-pox." 1858: "Analytical and Critical Review of the First Decennium of the Pathological Society of London." 1858: "Handbook of the Science and Practice of Medicine." This work reached a seventh edition. 1884: "On the Growth of the Recruit and the Young Soldier." A second edition of this work has been since published. 1885: "On the Doctrine of Evolution in its application to Pathology." 1886: "On the Animal Alkaloids." 1892: The first volume of the "Descriptive Catalogue of the Pathological Museum at Netley," already adverted to, is now in print and will shortly be published.

#### DR. ENRICO TANFANI.

SELDOM has a career of such promise been so sadly extinguished as that of this young and exceptionally able medical man. Dr. Tanfani had recently graduated, but even in his student days he had justified the brightest expectations already formed of him and was, as soon as he was eligible, appointed assistant to Professor Caruel in the Istituto di Studi Superiori at Florence, where he had passed through a scientific and professional curriculum with unusual credit. He had also been promoted to a mastership in the Collegio Militare of Florence and was gaining the esteem and affection of a constantly increasing *olientile* when he was overtaken by the accident that so prematurely cut short his life. A proficient, it appears, in the art of fencing, in which the Italians have long held a lead, he had lately succeeded to the post of President of the Circolo Fiorentino di Scherma (Florentine Fencing Club), and on the evening of June 14th he was engaged in a match with a very capable antagonist. All at once Dr. Tanfani gave a cry of pain and fell to the ground bathed in blood. His opponent, in making a lunge with considerable force, had not seen that his foil had lost its button and so the blade penetrated deeply into Dr. Tanfani's breast. He was conveyed at once to the Arcispedale di St. Maria Nuova hard by and found to be in a desperate condition. Every care that skill and devotion could lavish on him was taken, but he lingered only a few hours, dying of internal hemorrhage in the presence of his mother, the Countess Tanfani, and near relatives. The funeral took place on June 17th and was accompanied by a long train of colleagues and friends to the cemetery, where the body was afterwards cremated. His chief, Professor Caruel, made touching allusion in a brief *oraison funèbre* to his estimable qualities and to his career of promise arrested almost on the threshold and was followed in similar strain by more than one speaker, among them a pupil of the deceased. Every profession in Florence was represented by the mourners, the majority being equally divided between the medical school and the military college, with both of which Dr. Tanfani was officially connected.

## Medical News.

UNIVERSITY OF DUBLIN.—The following degrees were conferred last week:—

*Bachelor in Medicine, Surgery, and Obstetrics.*—J. Barcroft Anderson, William Bleazby, Robert James Coulter, Arthur James Cree, Charles Chatterton Deane, John Elliott, George Gower Fannin, Montagu Lawrence Griffin, Richard Henry Kennan, Sam. Mathews, Frederick Wm. Staunton, Charles Elrington Stokes, J. Thompson, Alfred Ernest Wales, Claude Ernest Wellington Wilmot.

*Doctor in Medicine.*—Theodore Bell, Joseph Blood, Rudolph Arthur Colston Burns, Harloe Henry Fleming (*In absentia*), Richard Lane Joynt, Richard Frederick McGrath, Thomas Myles, Brendan McCarthy, Robert William Henry Jackson, Richard Dancer Purfoy, Alfred Ernest Wales.

METROPOLITAN OPEN SPACES.—At a meeting held on the 23rd ult., at the Harlesden Court-house, it was unanimously resolved to recommend the Willesden Local Board to purchase Roundwood Park for a public recreation ground.

THE RETFORD DISPENSARY AND COLLEGE HOSPITAL.—The annual report for the past year shows that in the dispensary department 690 patients' tickets were issued and the cases attended to and eighteen hospital cases were treated. The financial position continued satisfactory; the balance in hand was £85 11s. 9d. in excess of the previous year.

**NEW SOUTH WALES.**—Active measures have been taken to organise a Sanitary Institute in Sydney; membership will be open to medical practitioners, sanitary engineers and architects. The object of the movement is to promote attention to all matters relating to sanitation.—A new Cottage Hospital of three wards with six beds has been opened at Walcha.

**SOCIETY FOR THE STUDY OF INEBRIETY.**—A quarterly meeting will be held in the rooms of the Medical Society, 11, Chandos-street, Cavendish-square, London, W., on Tuesday afternoon, July 5th, at 4 o'clock, the president, Dr. Norman Kerr, in the chair. Paper—"The Urgent Need for Improved Legislation for Inebriates"—H. W. Williams, M.D.

**CAMBRIDGE UNIVERSITY.**—Dr. Anningson and Mr. Robinson, M.A., will deliver a course of practical instruction in Hygiene at the Cambridge University during the long vacation, 1892. The course, commencing on July 9th, will consist principally of practical instruction in the sanitary examination of water, air and foods, chemically and microscopically, having special regard to the requirements of medical officers of health.

**ROSE SHOW AND FLORAL FÊTE.**—At the Mansion House on Friday afternoon, June 24th, H.R.H. the Princess Christian, accompanied by Princess Victoria of Schleswig-Holstein, opened a grand show and floral fete in the presence of a numerous gathering. The exhibits comprised one of the most magnificent collections of flowers ever got together in the city. The Lady Mayoress presided over the chief stall and the wives of the two sheriffs performed similar functions, Mrs. H. S. Foster being energetically seconded by Mrs. Edgar Jenkins, Lady Monkton, the Countess of Bective, Mrs. Frank Grimwood and Mrs. Soulsby, and many other ladies attended the stalls they had so generously decked and the Prince of Wales sent a large consignment of roses and carnations from Sandringham.

**BEQUESTS AND DONATIONS TO HOSPITALS.**—The late Mr. E. M. Bainbridge, of Eshott Hall, Felton, bequeathed £1000 each to the Fleming Memorial Children's Hospital, the Newcastle Dispensary and the Newcastle Infirmary.—Miss Mary Henderson, late of Berkeley Villa, Windsor-road, Southport, bequeathed, free of legacy duty, £1000 each to the Southport Infirmary, the Convalescent Hospital, Southport, and the Tumour Hospital, Rodney-street, Liverpool.—The Salters' Livery Company recently voted £52 10s. each to the Royal London Ophthalmic Hospital, Moorfields, Guy's Hospital and the New Mildmay Medical Mission Hospital.—Baron Hirsch has forwarded a further donation of £300, making a total contribution of £1000, to the Middlesex Hospital.—The Grocers' Livery Company has granted £100 to the National Hospital for Consumption, Ventnor.—The late Mr. A. Burr, of Halesowen, bequeathed £4000 to the General Hospital and £1000 to the Queen's Hospital, Birmingham.—Mr. Arthur Brooks, of St. Dunstan's-hill, London, has forwarded a donation of £500 to the Manchester Infirmary.—The late Mr. Robert Lock, of Blandford, bequeathed £1000 to the endowment fund of the Blandford Cottage Hospital.—Under the will of the late Mr. Peter Atrell, of Tredegar-square, Bow, his executors have recently distributed the following sums—namely, £2500 each to the London Hospital, the City of London Hospital for Diseases of the Chest and the East London Hospital for Children, £2000 to the Poplar Hospital and £1200 to the Royal Hospital for Incurables.—The Rev. C. A. Johnson, of Newbury, bequeathed £1000 to the Royal Hospital for Incurables, Queen Victoria-street, London.—Mrs. Eliza F. Ashton, late of Montacute-gardens, Tunbridge Wells, left by her will £250 to the Tunbridge Wells General Hospital and £100 to the Convalescent Hospital for Children, Hawkenbury, Tunbridge Wells.—The executors of the late Mr. R. A. Newbon have transferred to the trustees of the Great Northern Central Hospital £13,491 12s. 8d. Consolidated Stock (£15,000 less duty), being the amount of Consols bequeathed by the deceased to endow a ward, to be named the Newbon ward. This sum is only available for the maintenance of the ward.—We learn from Mr. Cheston, the chairman of the East London Hospital, that Baron Hirsch, who had already given £700 to the East London Hospital for Children at Shadwell, supplemented this handsome donation by a further sum of £300, which he presented on the occasion of opening the new out-patients' department of that institution by the Duchess of Portland on June 11th.

**HEAVY DAMAGES AGAINST A FRENCH JOURNALIST.** Judgment was given on June 30th in the action for libel brought by Mr. Milton, of the Kasr el Aini Hospital, against the French journal *Bosphore*, which published a violent attack on the English doctors and surgeons connected with the hospital. The court awarded the plaintiff £1000 damages, and ordered the insertion of the judgment in the *Bosphore* and two other papers.

**WEST LONDON HOSPITAL, HAMMERSMITH.**—Sir Algernon Borthwick, M.P., presided at the festival dinner in aid of this institution, which took place at the Hôtel Métropole last week. In proposing "Prosperity to the West London Hospital," the chairman stated that the hospital was founded in 1856 and during the thirty-six years of its existence 18,000 in-patients and upwards of half a million out-patients had been relieved at a cost of £143,000. The annual expenditure for maintenance and management was £6100. The present accommodation (101 beds) was now quite insufficient and efforts are being made to establish a wing to double that number. The land had been secured, but £40,000 is required for purposes of the building. Donations and subscriptions amounting to £2600 were announced.

**CHARING-CROSS HOSPITAL MEDICAL SCHOOL.**—Mr. J. Passmore Edwards presided at the distribution of prizes and certificates which took place at Charing-cross Hospital Medical School on Wednesday, the 29th ult. Proceedings were commenced by the Dean (Mr. Stanley Boyd), who read the annual report of the committee, from which it would appear that the annual increase in the number of students is maintained, whilst some valuable additions to the teaching staff of the school have also been made. In the honours list this year occur the names of Mr. G. H. Hooper, who took the Llewellyn Scholarship of £25; of Mr. D. P. Gabell, who secured the Golding Scholarship of £15, in addition to the prize for Practical Chemistry and certificates for both Anatomy and Physiology. The prizes for Practical and Forensic Medicine were awarded to Mr. W. T. White. The chairman pointed out the important position occupied by this hospital in the event of accidents, so many of which occurred in its immediate vicinity. "Charing-cross was the centre of London," he remarked, "London was the centre of English enterprise and England was the centre of the civilised world." A vote of thanks to the chairman, proposed by Sir Joseph Fyrrer, concluded the proceedings.

#### MEDICAL NOTES IN PARLIAMENT.

##### *The Scarlet Fever Case at Fulham.*

In the House of Lords, on June 23rd, Lord Sandhurst called attention "to the circumstances of the case of a child named Emily Williams, who was removed by order of the magistrate of the West London Police-court from the Middlesex Hospital to the West London Fever Hospital, under the idea that she was suffering from scarlet fever, although the said child had been for six days in the Middlesex Hospital, where there are plenty of means for isolation; and the child was in good health, with no signs of scarlet fever, according to two highly experienced physicians and other medical men." His lordship described at considerable length the details of the case. As to Dr. Cayley, he said he was a distinguished expert in fever. He went down to see the case out of pure philanthropy. He had no expectation of receiving any fee whatever. He saw the child and came to the strong conclusion that it had no symptoms of scarlet fever. He remarked that in the circumstances there was no need for the child going to the Fever Hospital, but that it should be taken to the Middlesex Hospital, where it would be attended to if scarlet fever should appear. Dr. Cayley said to the receiving officer that he would be obliged if he took the child in; there was a dispute as to whether it was a case of scarlet fever. It must occur that in a general hospital sometimes a patient was taken in ailing from something which eventually became scarlet or other fever and there was ample provision made in these general hospitals for such a case. As to the remarks of the magistrate, he did not think that Dr. Cayley's reputation was likely to suffer owing to what he (Lord Sandhurst) must term the intemperate remarks of the police magistrate. This gentleman said he would like to know what the hospital authorities and the people who subscribed to the charity would say and what course the College of Physicians would take. The board of the charity immediately passed a vote of confidence in Dr. Cayley and he (Lord Sandhurst) would be very glad to defend Dr. Cayley's conduct in taking the child into his own wards. More than that, he had had the opportunity of talking with the President of the College of Physicians, Sir Andrew Clark, and he said that Dr. Cayley was one of the most highly esteemed Fellows of the College and undoubtedly one of the highest authorities in London with regard to fever. He desired further to call the attention of their lordships to the question of the legality of the action of the magistrate. The Act provided that wherever there had not been isolation the child or other patient might be removed by order of the magistrate, but this patient was in a hospital where, as he had said, there was ample means of isolation and where the patient could

be as well treated as in the Fever Hospital itself. The magistrate said that in future he would grant these orders on the certificate of the medical officer of health without allowing any discussion whatever. Surely this was a tremendous power to put in the hands of a medical officer of health, who would practically issue all these orders himself. He would like to ask whether a medical officer of health with this large population to attend to should be allowed to continue in private practice. He understood that a petition had been presented for an inquiry into this case and he desired to support it. He very much feared that if a careful inquiry were made they would see this Act, which was intended for the benefit of the whole community, extremely unpopular and made almost unworkable. In conclusion, he might say he had taken up the matter in the public interest and he hoped the Government would give it their careful consideration.—Lord De Ramsey, one of the Lords in Waiting, replied on behalf of the Government. There was, he remarked, hardly anything that the noble lord had said, with the exception of a matter with which he would deal presently, as to the magistrate—there was hardly anything in which he could not most cordially sympathise with the noble lord. This had been in many ways a bad case and certainly it had been a very sad case; and he thought the very fact that the noble lord had brought it forward in this temperate way, knowing, as they all did, that he was chairman of the hospital and that a large part of his time was devoted to its work, would of itself do a great deal of good. As regards the medical officer of health taking private practice when he had the supervision of this large population, he could not own to have an opinion upon that. He was not prepared to answer that point. It was a point, however, that had not been raised in connexion with this case. With regard to what the noble lord had said towards the close of his remarks as to the effect that action taken in this case might have upon the working of the Act, he (Lord De Ramsey) thought he was perfectly justified and right. If, as the noble lord said, the authority wielded under the provisions of the Act, which was the London Public Health Act of last year, was arbitrarily to tear these children away from their parents, those children being subject to great differences of opinion amongst doctors, then he (Lord De Ramsey) said it was only another case where it was most absolutely necessary to exercise the supreme control of the Home Office to keep these officials in order. The noble lord knew of course that the medical officer of health had to be very careful in these matters. He had to take in time any cases of contagion which might spread rapidly into disease and cause much misery, but at the same time there was no question about it that when, as in this case, there was much difference of opinion amongst most competent men upon both sides, then he could not but think that although the diagnosis of the case might have been difficult, still it would have been more advisable for the medical officer of health to have paused a little, especially with such a weight of evidence against the child having scarlet fever at all. He desired to speak with the utmost caution as to the magistrate. The Secretary of State had not had the benefit of hearing the magistrate's views upon this case, as he was away on leave of absence, and he was sure his noble friend would not wish him to make any remarks without having been able to hear what the magistrate had to say. The unfortunate part of this business certainly arose in a local dispute, which undoubtedly was intensified by the mother's refusal to allow her child to go. In passing he would say that, although of course the mother behaved wrongly, at the same time she behaved most naturally, and one could not help regarding her action with some amount of sympathy. The noble lord wished to know whether there were means for isolation in the West London Fever Hospital. His reply was that there was every facility for isolation in that institution. He did not think he had anything to add.—The Earl of Kimberley said he was sure his noble friend (Lord Sandhurst) had not exaggerated at all the importance of this case. There was nothing more dangerous or more to be deprecated than the unwise administration of these somewhat arbitrary laws. He entirely approved of the laws of public health, but they must administer these laws carefully and judiciously. The point he did not at all understand in this case was how the magistrate could come to a decision that this child should be removed. He could not conceive upon what ground an order could be made for the removal of a child who was in a house where there were proper means of isolation. As to the magistrate's conduct generally, he agreed with the noble lord that they should exercise the greatest caution in speaking of magistrates in the discharge of their duty. One could only form a view from the report in the newspapers. But this he would say, that he was extremely glad that the Home Office had agreed to make an inquiry and if they should find after the explanation of the magistrate, that he had at all acted in the manner represented by the newspapers, he (Lord Kimberley) hoped the Home Office would in some way or other endeavour to prevent such vagaries in the future. On the other hand, he wished to state that perhaps the magistrate's explanation might clear him of all blame.—Their lordships then proceeded to the next business.

#### Casual Wards Bill.

Although this Bill passed through the House of Commons without opposition, the Government withdrew it when it reached the House of Lords. The withdrawal is understood to be due to the action of certain officials of local authorities, who brought before the President of the Local Government Board a number of practical objections.

#### The Royal Assent.

The Royal Assent was given by Commission on Monday to the following measures, which have passed both Houses of Parliament: Technical and Industrial Institutions Act, Contagious Diseases (Animals) Act, Galway Hospital Act, London Water Act, Bradford Corporation Waterworks Act, Swansea Corporation Water Act, Lanarkshire Middle Ward District Water Act, Birmingham Corporation Water Act, Exmouth and District Water Act, Pontypridd Burial Board Act, and Uttoxeter Water Act.

#### METROPOLITAN WATER-SUPPLY.

In continuation of the report of the evidence given by Dr. Edward Frankland, D.C.L., LL.D., F.R.S., before the Royal Commission on the Metropolitan Water-supply on June 21st, which appeared in our last issue, we give further evidence tendered by Dr. Frankland, setting forth his reasons why in his opinion the river Thames ought to be abandoned as soon as practicable for the supply of London. Witness gave detailed evidence as to the analyses of the Thames water after filtration.

Professor Dewar: So that you are not prepared to say that that water could not be treated for the purpose of a town supply?—Well, I think that opens up the whole question whether a river like the Thames, which receives even untreated sewage and a great deal of treated sewage, can be made into a perfectly safe water-supply, and I should not like to say that I consider that there is sufficient safety in the operations to which it is subjected before delivery to make it a perfectly safe water for a community to drink. I think you ought to have two or three lines of defence against the propagation of zymotic disease in the case of water supplied to a large community. We have already suffered in London by being too lenient in that respect. When we took the water from between the bridges we had a fearful epidemic of cholera in consequence.—Then I may put it in this way:—If you are not to be satisfied by 99 per cent. of the micro-organisms being removed by filtration, what would you recommend or where would you go in order to get a supply that would be satisfactory to your mind?—Go to the springs in the Thames basin and to deep wells to be sunk in the chalk and oolite and sometimes perhaps into the lower greensand. These waters I consider to be perfectly safe, if supplied to London even without filtration.—I will read that very admirable description of the varying conditions of the Thames in a report signed by yourself and also by Dr. Odling as early, I think, as the year 1863, and you will please say if you agree with it now:—"It is indeed evident that the Thames, in its flow from its source to Hampton, is constantly undergoing changes, now tending to purification, now to pollution; here it receives a tributary purer than itself and here is one more polluted; at one place it is pent up by a weir and flows sluggishly over a thick stratum of putrescent mud, then it dashes down the weir and flows as a rippling stream over a clean, pebbly bed, becoming aerated to the maximum; now it receives the sewage of a town and then it is reinvigorated by a gush of spring water in its bed, and these complicated changes are not merely affecting successive individual volumes of water as they flow on, but these volumes immediately afterwards lose their individuality, owing to the varying velocity of flow in different parts of the river section. No series of analyses, therefore, however great the number of samples or care bestowed on their collection, could, in the case of such a river as the Thames, illustrate exactly the changes produced in a stream by any one of the numerous causes of change above enumerated—the effect of the population residing on the banks for instance." Is that your opinion still?—It is.

In reply to Sir G. E. Bruce, witness stated that, while there was no positive proof that the filtered water is unwholesome, the lives of a large community ought not to be dependent on the efficient filtering-plant of commercial companies. Under present circumstances a serious epidemic of typhoid fever or cholera in the Thames basin above the intakes would be attended with great risk to the water drinkers of London. Such experiments should not be tried on large communities. Before the cholera outbreak of 1849 it was believed that Thames water, abstracted between bridges in London, was perfectly safe, as testified by the evidence of many eminent experts, but that belief cost London 25,000 lives in 1849 and 1854.

Dr. Ogilvie: You say that it is uncertain how far the numerous cases of zymotic disease occurring in the metropolis are traceable to the water-supply. I suppose you do not mean to imply that there is any doubt upon the subject as regards a considerable number of zymotic diseases—for instance, measles, scarlet fever, whooping-cough?—No, there is no evidence whatever that they are ever communicated through water, although there is no evidence that they are not.—No; but there was no reason to suppose that they are from anything we know is there?—Well, I believe that the virus of the zyme of scarlet fever is thought by competent authorities to be communicated through milk.—Which comes from cows that are affected with a certain disease?—Yes.—But through drinking water?—No, I do not think there is any evidence of it at all.—Then there is no risk?—I have never seen it even suggested that either scarlet fever, measles, or whooping-cough were communicated or communicable through water.—Have you ever seen it suggested by any bacteriological authority?—No, I do not think any of those have even suggested it.—Then which are the zymotic diseases to which you refer?—The bacillus of typhoid fever, the bacillus of erysipelas, although you must remember that several of these have never been found in drinking water. If they can live for a number of days in drinking water, it is possible they may be communicated.—But that is the only ground—the possibility of its living in water—on which you base your statement, is it not?—Yes; except in the case of typhoid fever and in the case of cholera, they have actually been found.—Those are, I think, the only two diseases that have ever yet been known to be communicated by drinking water among the zymotic diseases?—Yes, I think so, where it has been demonstrated.—That is typhoid fever and cholera?—Yes. But, taking the capability of living in river water, I should say that the bacillus of tuberculosis was probably most likely to be present in drinking water.—I am aware that the bacillus of tubercle has been said to live for seventy days in water, but it has never been known to be communicated to human beings by means of water?—No, it has not been demonstrated.—Then practically we may dismiss tuberculosis from the list of those which there is any risk of London suffering owing to drinking water from the Thames or Lea?—Yes, certainly; so far as our knowledge at present extends we have no right to presume it is ever so communicated.—Quite so; and, in fact, we come back to the two diseases practically being typhoid fever and cholera?—Yes, and those are the only two diseases that have been demonstrated to be communicable by water.—And as regards cholera bacillus, I think I understood you to say just now that where it was in river water, which contains a large number of competing microbes, it is soon destroyed?—Yes, that is the result of experiments made with this bacillus in river water.—So that the water that passes for any distance down the river, though it might have some cholera germs at the beginning, would soon have lost them?—Yes, that is very likely, at all events.—I think you are wrong in your recollection about the dejection of the man that you referred to who was working there for a very long time. You meant one man?—Yes, one man. The evidence that came to me at the time was that as a rule the dejections of the workpeople down those wells are brought up in buckets and that one bucket on being brought up was tipped over and some of its contents went into the well. I do not know how far that is true or not.—At any rate, that was not water from the Thames or the Lea?—No; it is not river water.—So far as any argument is to be drawn from that case at Caterham it would be that there is no greater safety in water derived from deep wells than

In water from rivers, because there you have a great outbreak of typhoid fever caused by water which you have repeatedly spoken of in your report as of the very highest quality?—Yes.—And of exceptional purity in this case?—Yes. No doubt great care ought to be taken in these cases when workmen are engaged in these wells.—But the Caterham case cannot be in any way cited as tending against the wholesomeness of the Thames and Lea water?—No, I am not putting it on all fours with what would occur in any river. In the first place we must remember that the water as it exists in the well is absolutely free from microbes, therefore the typhoid microbe might have it all its own way there.—I would ask you whether the fact, supposing it to be a fact, that towns which have drunk filtered water from those rivers suffer very little from typhoid fever is not evidence that such water is wholesome?—No, I do not think it is conclusive evidence that typhoid fever is not in some cases, if not in all, conveyed to them by water. Take London, for instance. I never thought that it was impossible that the typhoid fever existing in London continually is not propagated and brought to London, in part, at all events, by the water-supply of London.—But there have been a great many inquiries into typhoid fever outbreaks in London and are you aware that any one was ever traced to the drinking water from the Thames or the Lea?—I think it would be quite impossible to do so.—There have been many traced to milk?—Yes.—But you are not aware that ever any were traced to water?—No; I cannot imagine how it could be done, supposing there were ten times as many cases. You see the Thames water is distributed all through London.—It would be possible, would it not, supposing it was given by the Lea river and not by the Thames, that you would then find a huge outbreak attacking all those areas in which the Lea water was distributed and avoiding all those districts to which the Thames water was delivered?—Yes; if the Lea were exceptionally polluted by typhoid fever sewage there ought to be a difference in the number of cases of typhoid fever in the New River district of the East London Companies; but then I am not aware that that has ever really been investigated.—Do you not think that it is evidence that the filtration of this water has rendered it wholesome, or that it was wholesome before it was filtered, one or the other; that the death-rate from typhoid fever in London in the last twenty years has been lower than in the country at large?—Yes, and it has been very much lower than it used to be in London.—It has been lower all over the country?—Yes, it used to be very much higher than it is now and the lowering has been coincident with the great improvement in the filtration in the water delivered in London, though I do not mean to say that the one is necessarily the cause of the other.—But that lowering has gone on concomitantly with a lowering in the rest of the country?—Yes.—But was not that also been coincident with the improvement in the water-supply?—It may have been possible.—But at any rate the death-rate in London from typhoid fever being lower than that in the country at large is, so far as it goes, evidence that the water which the Londoners consume is not such as is likely to give typhoid fever?—Yes, I think it is decidedly a piece of evidence in favour of the water.—Then, in the face of that, do you think you could maintain the opinion you have expressed that there is not a tittle of trustworthy evidence in support of the view that the filtration of water is effective as a safeguard?—I do not say that there is not evidence that it is a safeguard, but I say there is no evidence of the impossibility of those syzygial germs passing through the filters; that is what I mean. There is no tittle of evidence to show that a pathogenic germ cannot pass through a filter. I do not consider that we have any positive evidence that water which is contaminated with typhoid fever poison becomes absolutely free from it after the same filtration given to it by the water companies can be absolutely free from every risk.—Is the filtration at present adopted and carried out by the London water companies to your mind as perfect as it can possibly be?—I think it is very satisfactory; I do not mean to say that if the filtered water were not passed through a second filter you might still further reduce the number of microbes, but it is exceedingly satisfactory filtration to my mind.

Professor Dewar: Have you had the opportunity of studying the bacteriological condition of a filter when it is most efficient in artificial filtration?—No; I have not. I intend to do so, but have not been able to do so up to the present moment.—Do you know that sterilised sand would be useless for the purification of these waters?—Yes, I do know that.—Therefore the efficiency of the artificial filter depends upon the life of a number of these micro-organisms?—I think it is very likely to be so.—I dare say you are quite aware that it is quite in harmony with the most recent investigations with regard to nitration?—Yes.—And you would regard it as a proof that the organic matter was being apparently attacked by the increase in the amount of nitrates?—Yes.—Consequently we know that the increase in the amount of nitrates is entirely due to microbial action?—Yes.—Therefore the efficiency of the artificial filtration is the result of microbial action?—Yes, certainly, one part of it is; but I am not at all certain from these experiments that there is not also some surface action in the case of a sand filter. When you have fresh sand and, if you like, sterilised sand you would still remove some organic matter from the water.

Sir A. Geikie: Before you leave that I would like to ask you whether you have observed any difference between water taken from a new filter and water taken from one that has been in use for some time with regard to microbes?—That is exactly the problem I am setting myself to establish now, but it has not yet been done.

Professor Dewar: You cooperated with Dr. Klein in this investigation as to the supply, at any rate, and you were in consultation with him on the bacteria in London water?—Yes, last year I determined the number of microbes, but it was Dr. Klein alone who attempted to distinguish them. He was supplied once a week for six consecutive weeks with sealed tubes of the London water.—You are aware of this passage in Dr. Klein's report: "In a good many instances the colonies or their sub-colonies were tested on animals, in order to ascertain whether they possessed pathogenic action or whether some of them at first sight have been taken for animal action connected with a certain amount of pathogenic bacteria." That was what you recommended in the evidence this morning, that it was necessary definitely to infect animals?—Certainly.—Dr. Klein also states: "Before proceeding further to the details of the result, I may state that in no case have I come across any of the known pathogenic bacterial species or of any species that produce on the animals experimented upon—guinea-pigs, mice and rabbits—definite pathogenic action." You are aware of that?—Yes.

Sir A. Geikie: We shall be very pleased indeed when you have completed those investigations if we can have the result of them.

Dr. Frankland: I shall take care that they are placed in the hands of the Commission.

The Commission adjourned till Monday.

On Monday Dr. George Turner, M.B., D.P.H.Camb., Medical Officer of Health for the Counties of Herts and Essex combined, Lecturer on Hygiene at Guy's Hospital and Examiner on State medicine at the Royal College of Physicians and Surgeons, gave evidence as to the pollution of the river Lea and also instances in which the river water had produced typhoid fever. He disagreed with Dr. Frankland in supposing that the non-pathogenic bacteria, the innocent bacteria, fed upon the pathogenic bacteria, so that the presence of a large number of them was distinctly an advantage. That depended entirely upon the sort of microbe organism that happened to be present in the water. Some of them do certainly destroy others.

On Tuesday Mr. Shirley Forster Murphy, Medical Officer of Health of the County of London, stated the results of his investigations made of the pollutions of the Thames and the Lea. Speaking with reference to the protective measures adopted by the water companies for the purification of the water, witness added: "I may, however, submit that, even if it is admitted that polluted streams may, after running some distance, become purified, there is no definite knowledge as to the point where danger ends and safety begins and rivers receiving excremental pollutions must therefore be regarded with some misgiving as sources of public water-supply."

Mr. William Joseph Dibdin, Fellow of the Institute of Chemistry and Chemist to the London County Council, also gave the results of his investigations with regard to the composition of the water supplied to London, after which the Commission adjourned until Wednesday, July 20th.

### METROPOLITAN ASYLUMS BOARD.

Return of Patients remaining in the several Fever Hospitals of the Board at Midnight on June 28th, 1892.

Hospital.	Beds occupied.					Total accommodation.
	Scarlet fever.	Diphtheria.	Typhus fever.	Enteric fever.	Other diseases.	
Eastern Hospital	335*	60	1	23	—	424

Northern	655	21	—	—	—	676
Totals	2063	237	1	51	7	2359

\* Infant and mother.

SMALL-POX. *Atlas* hospital ship, 35; *Castalia*, 22. Total, 57.

### Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

BACK, H. H., M.B. Lond., M.R.C.S., has been appointed Medical Officer for the No. 5 Sanitary District of the Aylsham Union, vice Beeve, deceased.

BARRATT, J. O. W., M.D. Lond., F.R.C.S., has been appointed Medical Officer at the Infirmary, Parish of Birmingham.

BETTS, F. BERNARD, M.R.C.S., L.R.C.P., has been appointed Resident Medical Officer to Queen Charlotte's Lying-in Hospital, Marylebone-road, N.W.

BROWNING, GEORGE, M.R.C.S., has been reappointed District Medical Officer and Medical Officer of Health for the Wertley Union.

CAMPBELL, A., M.B., C.M. Glasg., has been appointed Medical Officer for the Ratcliffe-on-Trent Sanitary District of the Bingham Union.

CARTER, A. H., M.D. Lond., M.R.C.S., has been appointed Medical Officer at the Infirmary, Parish of Birmingham.

DE HAILES, A. J., has been appointed Public Analyst for the Borough of Luton, vice Redwood, deceased.

DUNN, E. D., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Public Vaccinator for the District of Motueka, New Zealand.

ENGLISH, JOSEPH, L.R.C.P., L.R.C.S. Edin., has been appointed Visiting Surgeon to the Gaol at Yass, also Government Medical Officer and Vaccinator for the District of Yass, New South Wales.

FENWICK, W. SOLTAN, M.D. Lond., M.R.C.P., has been appointed Physician for Out-patients to the Evelina Hospital for Sick Children.

FERGUSON, A. A., L.R.C.P., L.R.C.S. Irel., has been appointed Medical Officer of the Workhouse, Aston Union.

FRANCIS, H. A., M.B. Camb., L.R.C.P. Lond., M.R.C.S., has been appointed Government Medical Officer at Barcardine, Queensland.

GORDON, J. M., M.B., C.M. Glasg., has been appointed Resident Medical Officer to the Melbourne Hospital, Victoria, Australia.

HICHTENS, FRANK, M.D. Lond., M.R.C.S., has been appointed Medical Officer of Health for the Urban Sanitary District of the Redruth Union.

JAMIESON, SYDNEY, M.B., C.M. Edin., has been appointed Honorary Pathologist to the Sydney Hospital, New South Wales, vice Rennie, resigned.

JEWELL, J. W. F., L.R.C.P. Lond., M.R.C.S., has been appointed Assistant House Physician to Guy's Hospital.

KENDALL, H. W. M., M.R.C.S., has been appointed Surgeon Superintendent to the Wesleyan Hospital, Hokitika, New Zealand.

MANN, J. DIXON, F.R.C.P., has been appointed to the Professorship of Medical Jurisprudence now instituted at Owens College, Manchester.

MARSH, JAS JOHN, L.R.C.P., I.R.C.S., L.M., has been appointed Medical Officer to the Post-office, Ormskirk.

MAUDSLEY, H., M.D. Lond., M.T.C.P., has been appointed Honorary Physician to the Alfred Hospital, Melbourne, Australia, vice Thomson, resigned.

MCNICOLL, JOHN, L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer to the Poole and Parkstone Post-offices.

MORITZ, S., M.D., M.R.C.P. Lond., has been appointed Honorary Physician to the Manchester Hospital for Consumption and Diseases of the Throat and Chest.

NATHINGE, G. J., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Health Officer, Stawell Borough, Northern and Western Wards, and the Stawell Shire, North and West Ridings, Australia.

NASH, CHAS., M.E.C.S., has been appointed Medical Officer of Health for the Rural Sanitary District of the Catherington Union, vice Strong, resigned.

RAKE, A. T., M.B., B.S., L.R.C.P. Lond., M.R.C.S., has been appointed House Surgeon to Guy's Hospital.

ROBERTS, E. T., M.D., C.M. Edin., has been appointed Certifying Surgeon under the Factory Acts, vice A. Roberts, resigned.

RUTHERFORD, J. J., M.D. St. And., L.R.C.P. Edin., L.F.P.S. Glasg., has been reappointed Medical Officer of Health for the Shipley Urban Sanitary District.

SALTER, C. E., M.B., B.S., L.R.C.P. Lond., M.R.C.S., has been appointed House Physician to Guy's Hospital.

SAMUELSON, G. S., M.B. C.M. Edin., has been appointed Government Medical Officer and Vaccinator for the District of Gundagai, New South Wales.

SHORT, T. S., M.D. Lond., M.R.C.S., has been appointed Medical Officer at the Infirmary, Parish of Birmingham.

SMYTH, T. E., M.D., B.Ch. Dub., has been appointed Government Medical Officer and Vaccinator for the District of Campbelltown, New South Wales.

SNADDEN, JAS., M.B., C.M. Edin., has been reappointed Medical Officer of Health for No. 1 and No. 4 Sanitary Districts of the Wortley Union.

SPARK, J., M.R.C.S., has been appointed Government Medical Officer and Vaccinator for the District of Katoomba, New South Wales.

SPOWART, THOS., L.R.C.P., L.R.C.S. Edin., has been reappointed Medical Officer of Health for the Second Sanitary District of the Wortley Rural District.

SYMONS, J. G. R., L.R.C.P. Edin., M.R.C.S., has been appointed Medical Officer for the Shepperton Sanitary District of the Staines Union.

TEBBS, W. H. A., L.R.C.P. Lond., M.R.C.S., has been appointed House Surgeon to Addenbrooke's Hospital, Cambridge.

THOMAS, A., M.B., B.S., L.R.C.P. Lond., M.R.C.S., has been appointed House Physician to Guy's Hospital.

TOSSWILL, J. CECIL, M.B., C.M. Edin., has been appointed Visiting House Surgeon to the Infirmary, Stockport, vice Hamilton, resigned.

VALENTINE, T. H. A., L.R.C.P. Lond., D.P.H., M.R.C.S., has been appointed a Public Vaccinator for the District of Inglewood, New Zealand.

WALLACE, RICHD., L.R.C.P. Edin., L.F.P.S. Glasg., has been appointed Public Vaccinator for Millicent, South Australia.

WAUGH, ISAAC, M.B., M.Ch. Dub., has been appointed Medical Superintendent of Government Asylums for the Infirm and Destitute at Parramatta, New South Wales.

WESTWOOD, H. O., L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer for the Bingham Sanitary District of the Bingham Union, vice Wotton, resigned.

WILKINSON, E. W. C., L.F.P.S., L.M. Glasg., has been appointed Public Vaccinator for the District of Rangitikei, New Zealand.

WINGRAVE, V. H. WYATT, M.R.C.S., L.S.A., has been appointed Assistant Surgeon to the Central London Throat and Ear Hospital.

## Vacancies.

For further information regarding each vacancy reference should be made to the advertisement.

ANCOATS HOSPITAL, Manchester.—Resident Junior House Surgeon. Salary £50, with board and washing.

BOROUGH OF SCARBOROUGH.—Medical Officer of Health for the district of the borough for one year. Salary £326 per annum.

## Births, Marriages, and Deaths.

### BIRTHS.

DUKES.—On June 26th, at Sunnyside, Rugby, the wife of Clement Dukes, M.D., B.S. Lond., of a son.

NANKIVELL.—On June 20th, at Langham-street, W., the wife of Herbert Nankivell, M.D., of a daughter.

WALKER.—On June 23rd, at Rocklands, London-road, St. Leonards-on-Sea, the wife of Alexander Walker, M.D., of a son.

WISE.—On June 23rd, at Dunheved, Walthamstow, the wife of C. H. Wise, M.D., of a daughter.

### MARRIAGES.

COCKILL—SEELY.—On June 20th, at St. Peter's, Cherry Willingham, Lincolnshire, William Baron Cockill, M.E.C.S., L.R.C.P. Lond., of Kendal, Westmoreland, to Edith Mary, third daughter of Mr. Robt. Seely, of Manningdale, Cherry Willingham.

CRAIG—AITKEN.—On June 23rd, at St. Saviour's Church, Bridge of Allan, William Maxwell Craig, M.B., Surgeon Royal Navy, to Janet Georgina, daughter of the late Archibald Robertson and widow of Stephen Rowan Aitken.

DUTHIE—MCLEAN.—On June 23rd, at St. Mary Abbots, Kensington, Robert Campbell Duthie, M.A., M.B., C.M., D.P.H., Croydon, to Eliza Douglas McLean, daughter of Alexander McLean, Esq., of Kensington.

FAULKNER—WEBB.—On April 20th, at St. Andrew's Parish Church, Brighton, Melbourne, William Cooke Faulkner, M.B., C.M. Edin., of the Hospital, Rockhampton, Queensland, to Ada, daughter of Captain T. Webb, of Melville, Brighton, Melbourne.

FISHER—DARLING.—On May 23rd, at St. Paul de Loanda, Walter Fisher, M.R.C.S., son of William Benjamin Fisher, of Greenwich, to Susannah Elizabeth Darling, daughter of J. S. Darling, of Clonakilty, Ireland.

LEE—MORGAN.—On June 22nd, at St. Philip's Church, Earl's-court, Edward Samuel Lee, M.D., M.R.C.S., St. Leonards-on-Sea, son of the late Dr. Robert Lee, F.R.C.P., F.R.S., to Fanny Caroline, widow of the late Captain Morgan, 4th Battalion Royal Fusiliers, and elder daughter of the late Thomas Huggins, Esq., of Collingham-road, South Kensington.

PRICE-JONES—EYSEN.—On June 22nd, at St. Mark's, Surbiton, Dr. Cecil Price-Jones, of Surbiton, son of the late William Price-Jones, M.D., to Helen Louise, youngest daughter of Gottfried Eysen, of Surbiton.

### DEATHS.

AITKEN.—On June 25th, at Woolton, Southampton, Sir William Aitken, M.D., F.R.S., Professor of Pathology, Army Medical School, Netley, aged 67.

BARR.—On June 23rd, suddenly, at Bembridge, Isle of Wight, William Alexander Barr, M.D., aged 70.

FRASER.—On June 23rd, at St. Helen's-road, Swansea, Thomas Alexander Fraser, M.D., M.R.C.S., eldest son of Surgeon-General John Fraser, C.B., aged 81.

HARMER.—On June 10th, at Alton Lodge, Richmond, Robert Harmer, M.D., aged 68.

N.B.—A fee of 6s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

## Notes, Short Comments &amp; Answers to Correspondents.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*All communications relating to the editorial business of the journal must be addressed "To the Editors."*

*Lectures, original articles, and reports should be written on one side only of the paper.*

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher." We cannot undertake to return MSS. not used.*

## THE POLICY OF THE ASSOCIATION OF FELLOWS OF THE ROYAL COLLEGE OF SURGEONS.

Mr. W. T. Law's letter on this point is too long for insertion, and more especially because it is written with an imperfect knowledge of the subject. The lack of organisation on the part of the Fellows is the fault of the Fellows themselves, who have only to join the Association in order to direct its policy and secure all the privileges which they can possibly desire. The resolutions on which the Association was founded were drafted and proposed by Mr. Paul Swain and only referred to the Fellows of the College; but at the first general meeting at the College the Members so far outnumbered the Fellows that it was found that it would be impossible to carry the resolutions unless the words "and Members" were introduced into three of them. At all the general meetings of the College, owing to the Fellows and Members being summoned indiscriminately by the Council, the experience has been the same; and this fact made it necessary for the committee of the Association some years ago to endeavour to settle the claims of the Members. A compromise was effected, but the Members' Association did not adhere to it. They went beyond it and raised a strong antagonism against their claims amongst the Fellows of the College and in the Association itself, which naturally determined to devote its energies entirely to advancing the interests of the Fellows. This policy has been steadily pursued for the last few years and that it has been successful will be seen in the pages of the Report of the Association just issued, which we recommend our correspondent to peruse, believing that his views will undergo considerable modification afterwards. He should also peruse the first account, published in 1890. Mr. Tweedy is a staunch champion of the claims of the Fellows to a larger share in the government of the College and by returning him to the Council the Fellows will do much to remedy the disappointment which is felt by our correspondent in regard to the "so-called advantages about to be granted to the Fellows by the Council." So far as they go these advantages are due in large part to the action of THE LANCET and of the Association; and in proportion to the support accorded to the Association by Fellows like our correspondent will the advantages and privileges of the Fellows increase. The Association returned one of its candidates last year and as its influence is extending there is every reason to anticipate Mr. Tweedy's success on the present occasion.

*Weekly Reader.*—The bill sent us (intended for exposure in chemists windows and other public places) seems to us objectionable. We quite recognise our correspondent's wish not to disregard the whole-some rules of professional life.

FEATS OF A FAKIR.

At Bologna one of those mysterious devotees or fanatics who impose on themselves penances of the most painful, often revolting, kind has been exhibiting before wondering assemblies a series of marvels which Professor Albertoni of the University had no difficulty in exposing as tricks. The professor, in a physiological lecture delivered *ad hoc*, took the first incidents of the fakir's performance, those of swallowing venomous reptiles and causing serpents of a known poisonous family to bite him—both without harm to himself. Redi had long ago demonstrated that the introduction of noxious creatures into the stomach may be practised with impunity, the gastric juice being quite adequate to antagonise them. Again, Professor Albertoni showed his audience how the bite inflicted on the fakir by a poisonous snake may be quite innocuous if certain precautions were taken. The poison of the animal is secreted by a glandule and has its exit from an orifice which opens at the apex of the tooth. This orifice is effectually plugged by making the animal bite wax and so the fakir allowed himself to be bitten thereafter with impunity. Yet again, the poison after even one effective bite is completely evacuated from the tooth and so, having bitten sundry objects repeatedly, the animal has for the rest of the day none of its poison available, till this is once more matured and secreted by the glandule. In this way the fakir might expose himself to any number of secondary bites without danger. The insensibility and "invulnerability" to which the fakir had inured himself is also susceptible of physiological explanation. Professor Albertoni had no difficulty in demonstrating to his hearers the dependence of sensibility on the cerebral cortex and how by practice and special long-continued exercise the sensibility may be first wrought up to its most exquisite point and then exhausted, till for a time it is virtually abolished. This temporary suspension of sensibility the fakir promoted or assisted by exposing himself to the vapours of particular herbs, while also going through a series of motions—mesmerising himself, in fact. In this way he had by "auto-suggestion" trained himself to lapse into a state of lethargy, suppressing the function of the cerebral cortex and inducing an insensibility which he represented as invulnerability. Professor Albertoni's interesting lecture is, we believe, to be printed for the benefit of a wider and non-professional public.

A.—Our correspondent's paper is receiving attention and will appear, if possible, in an early number.

MEDICAL AID ASSOCIATIONS.

To the Editors of THE LANCET.

SIRS,—The tone and tenour of several questions put to Dr. Martin of Stourport when before the General Medical Council are the excuses for this letter. Probably it will interest the body of general practitioners and possibly the Medical Defence Union. The facts are culled from the last report of the Conference of the Friendly Societies' Medical Alliance, dated March 8th, 1891. Leamington, Ashford, Preston and Reading all had unqualified medical officers in their employ. At Ashford, at any rate, the unqualified man did about half the work—took the country round one week and town the next. Birmingham had a balance of £1441 16s. 1d.; Derby of £1011 16s. 7d. Is it profit or not? The Leicester Foresters' Society laconically state they have "twelve doctors." In reply to the gentleman who asked the week before last whether the agreements were binding, I beg to say I think they are; but some of the distances debarred are outrageous—seven miles—and could no doubt be successfully disputed on the general principle that no one can prevent a man's earning a living in a reasonable way. As one who has had two such appointments, my advice to any needing it is: Never seek such an appointment. Do not be allured by the salary. The work is hard; the position, without plenty of backbone and numerous fights with a committee probably of twenty-five men (some of whom it would puzzle to write their names), is servile and the petty annoyances innumerable, and worse, it is difficult to get any ordinary berth after holding such a one.

I am, Sirs, yours truly,  
H. W. D.

LONGEVITY AMONG ABSTAINERS.

Two correspondents direct our attention to the respective mortality of the General Section and the Temperance Section of the Sceptre Life Association as shown in the twenty-seventh annual report for the last eight years. The number of lives under observation is over 12,000. The results are as follows:—

	Expected deaths.	Actual deaths.	Percentage.
General Section	704	620	78.03
Temperance	307	204	66.58

THE GREENING OF PEAS.

Dr. Russell (Glasgow).—We have ascertained that there is no enactment under the French law which prohibits the use of copper salts for giving a green colour to vegetables, just as there is no restriction on the import of tinned greened vegetables. But the law says makers of such goods are answerable for any injury that may be caused to health by the consumption of articles coloured with poisonous salts.

NEWSPAPER PUFFS OF MEDICAL MEN.

THE *Globe* has a very dignified annotation on the unseemliness of such puffs. An eminent pianist, in the innocence of his heart, thought to do his physician a good turn by sending a little paragraph the round of the papers praising his skill and success. Our contemporary very properly declined to publish such stuff. It received a second paragraph of the same sort, and was equally firm, feeling that the science of medicine is "too noble" to be degraded to the level of rival soap-boilers." We thank the *Globe* for the stand it so properly takes, and trust other contemporaries will take note of this example and follow it.

B. B.—The Local Government Act of 1888 provides that no person shall after Jan. 1st, 1892, be appointed the medical officer of health of any county, or of any such district or combination of districts, as contained according to the last published census for the time being a population of 50,000 or more inhabitants unless he is legally qualified for the practice of medicine, surgery, midwifery and also is either registered in the Medical Register as the holder of a diploma in sanitary science, public health, or State medicine under Section 21 of the Medical Act, 1880, or has been during three consecutive years preceding the year 1892 a medical officer of a district or combination of districts with a population according to the last published census of not less than 20,000, or has been before the passing of the Local Government Act for not less than three years a medical officer or Inspector of the Local Government Board. Our correspondent will observe that these requirements only relate to districts having more than 50,000 inhabitants at the time of the last published census.

ANTIDOTES TO ANÆSTHETIC NARCOSIS.

To the Editors of THE LANCET.

SIRS,—In cases of chloroform narcosis, such as that reported by Mr. Jordan Lloyd in THE LANCET of to-day's date, I would strongly recommend oxygen gas inhalation. Impressed with its great value in Sir H. Davy's case of carbo-hydrogen poisoning in the Hotwells' Hospital, I included it amongst the antidotes for anæsthetic narcosis in my book, "Anæsthetics, Ancient and Modern." During the past two years I have frequently used the oxygen gas in cases of asphyxia and always found it a reliable, quick-acting remedy. Messrs. Fannin of this city manufactured for me an efficient and inexpensive apparatus for its administration. I am, Sirs, yours truly,  
Dublin, June 25th, 1892.

GEORGE FOY, F.R.C.S.I.

THE VALUE OF MASTICATION.

DR. LAUDER BRUNTON, in the course of a recent lecture on Mastication at St. Bartholomew's Hospital, made use of the following remarks:—"I think it was a magnificent stroke of genius on the part of the President of the Royal College of Physicians, Sir Andrew Clark, when he informed Mr. Gladstone that he had one mouth and thirty-two teeth and that for every mouthful of food he took every tooth should have a chance, so that he should take thirty-two bites to every mouthful. And," continued Dr. Brunton, "if the patient has lost some of his teeth he should allow two bites for every missing tooth and even that will not always do if many teeth have gone."

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. A. G. Auld, Glasgow; Mr. W. Anderson, London; Mr. Atkinson, Sherborne; Mr. Buss, Hendon; Mr. Bourke, Wolverhampton; Dr. Lauder Brunton, London; Mr. T. B. Browne, London; Messrs. NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post Offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance. Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 66, Rue Caumartin, Paris.

# SAVORY & MOORE'S BEST FOOD FOR INFANTS.

The attention of the Medical Profession is especially requested to the following characteristics of this old-established **SELF-DIGESTING Food**, which has so thoroughly maintained its reputation for superiority during an experience of 30 years:—

Ratio of Albuminoids to carbohydrates.

The ratio of the albuminoids to the carbohydrates is the same as in human milk—viz., 1 to 6·4; the ratio in cow's milk being only 1 to 3·8.

Albuminoids easy of digestion, not pre-digested.

The albuminoids are not predigested as in pancreatised foods, but are rendered easy of digestion, leaving (as in human milk) just sufficient work to strengthen and develop the immature digestive powers, instead of weakening and abrogating them by keeping them inactive. Sir WILLIAM ROBERTS'S experiments in feeding kittens show that distinct failure of nutrition occurs when the milk is predigested (peptonised), and the same thing has been observed in feeding infants, probably owing, as THE LANCET points out, to atrophy of unemployed glands.

Healthy nature of evacuations.

As a consequence of the foregoing the proper peristaltic action of the bowels is maintained, and the healthy nature of the evacuations of infants fed on this food is a satisfactory feature much and favourably commented on by Mothers and Nurses.

The curdling of Cow's milk prevented

When mixed with cow's milk it prevents the troublesome curdling in the stomach which takes place when cow's milk is given alone, and assimilates its composition to that of human milk.

Complete conversion of the starch

The active Malt Diastase present provides for the rapid and complete conversion of the starch at the time of mixing into the soluble assimilable products of maltose and dextrine. The point of the gelatinisation (thickening) of the Food—viz., 140°F.—is just that at which Malt Diastase is most active, and the conversion of the starch is consequently the work of a very few minutes only.

Retention of the Phosphates and Fat.

The retention of the fat and of the phosphates of the wheat and malt, which are so essential to bone formation. These exist chiefly in the outer portions of the grain, the very parts which some manufacturers pride themselves upon so successfully rejecting.

Absence of fermentable sugar.

The absence of the fermentable sugar, which in the various malt extracts and milk foods so often gives rise to Diarrhoea and Flatulence.

Verdict of Jury as to inferiority of imitations.

It is the *only* Infants' Malted Food which obtained a Gold Medal at the International Health Exhibition, the Jury being comprised of such authorities as Dr. ATTFIELD, F.R.S.; G. W. WIGNER, F.I.C., the then President of the Society of Public Analysts; Dr. JAMES BELL, F.R.S., the Head of the Government Laboratories; and other distinguished Medical and English and Foreign Experts. This affords significant indication of the value to be attached to the numerous imitations, which, whilst pirating the descriptive notices of the Food, utterly fail to approach its standard of excellence.

**SAVORY & MOORE,**  
143, NEW BOND STREET. LONDON, W.

The Croonian Lectures

ON THE

CHEMISTRY AND THERAPEUTICS OF URIC-ACID GRAVEL AND GOUT.

Delivered before the Royal College of Physicians of London,

By SIR WM. ROBERTS, M.D. LOND., F.R.S.

LECTURE III.

CHEMISTRY OF URATIC PRECIPITATION IN GOUT.

MR. PRESIDENT AND GENTLEMEN,—The chemistry of gout in its full extension embraces changes of the most diverse character in the blood and tissues. I do not propose to deal with the subject in this comprehensive sense, but to confine myself entirely to the relations of gout with uric acid. By far the most characteristic feature of gout is the formation of chalk-like deposits in certain parts and tissues of the body, especially in and about the joints. The essential component of these deposits is the bi-urate of sodium, and it is always present in the crystalline condition. The crystals are distributed through the implicated tissue in the form of delicate needles aggregated into tufts, bundles, and stars. The arthritic incidents of gout may be said, not improperly, to be simply incidents pertaining to the precipitation of these crystals in the structures of the joints. Without the occurrence of this precipitation the gouty paroxysm could not take place, nor could the more chronic changes in the joints, with their train of attendant symptoms, follow after. Were it possible for us to keep the sodium bi-urate in a state of solution in the bodily fluids, the clinical portraiture of gout would be completely transfigured. Whatever other manifestations of the gouty constitution we might have to deal with, we should not have to contend with this most grievous outcome of the diathesis. The evidence brought forward by Sir Alfred Garrod on this point appears to me to be conclusive, and justifies the deduction that the deposition of the crystalline bi-urates is not merely a concomitant, but is the actual cause of the joint troubles of gout. This view is now pretty generally accepted, and forms the basis of most of our plans of treatment in the management of the gouty state. Hence it is that the history and chemical properties of sodium bi-urate have acquired a capital importance in the pathology of gout. We are interested to know how this compound arises in the body from nascent uric acid, what are its relations of solubility in diverse media and more particularly in the blood and lymph and synovia; what are the factors which tend to determine its precipitation in the body or tend to prevent its precipitation.

I have before adduced evidence to show that the normal or physiological condition of uric acid in the body is that of a quadri-urate and that any departure from this condition must be regarded as pathological. In the last lecture I traced the changes which the quadri-urate undergoes in the urine and which lead up to the separation of uric acid in the free state as gravel and urinary sediments. In the present lecture I shall endeavour to trace the converse changes which the quadri-urate undergoes in the blood and lymph and which lead up to the formation and deposition of sodium bi-urate in the tissues. In order to effect this purpose I propose, first, to examine the solubility of the material of gouty concretions—namely, sodium bi-urate—in various media: in the serum of the blood, in synovia and in diverse saline solutions; then to examine and compare the behaviour of free or uncombined uric acid with the same media. Upon the basis of the results thus obtained I shall be able to formulate a general theory of uratic precipitation.

SOLUBILITY OF SODIUM BI-URATE IN DIVERSE MEDIA:

(a) IN WATER, (b) IN BLOOD-SERUM AND KINDRED MEDIA, (c) IN VARIOUS SALINE SOLUTIONS.

(a) *Solubility of Sodium Bi-urate in Water.*—When sodium bi-urate is digested at blood heat with pure water it enters pretty freely into solution. Careful experiments indicated that the solubility of sodium bi-urate in distilled water at 100° F. approximated very closely to the proportion of 1 part in 1000. This was taken as the standard of comparison in estimating the solubility of this compound in all other media.

(b) *Solubility of Sodium Bi-urate in Blood-serum.*—Sodium No. 3593.

bi-urate is very sparingly soluble in the serum of the blood; as is shown by the following experiments. Sodium bi-urate in excess was treated with blood-serum of the horse and pig in corked phials. The phials were placed in the warm chamber and frequently agitated. After a digestion of twelve hours the supernatant serum was filtered twice through a threefold filter.<sup>1</sup> The filtrate thus obtained, when acidulated with acetic acid, gave not the slightest precipitation of uric acid. Nevertheless, some slight solution had taken place. For when a portion of the filtrate was evaporated on a watch-glass in the warm chamber to near dryness, needles of bi-urate could be readily detected in it under the microscope, or when the filtrate was tested with Garrod's thread experiment crystals of uric acid were always found sprinkled on the thread. It thus appears that sodium bi-urate, although very sparingly soluble, is not absolutely insoluble in blood-serum. From a number of comparative experiments I estimated that at blood heat the amount dissolved was probably about 1 part in 10,000.

The behaviour of sodium bi-urate with synovia corresponded exactly with its behaviour with blood-serum; only minute traces went into solution. It was ascertained by direct experiment that the behaviour of uric acid and its compounds with blood-serum depended entirely on the saline ingredients contained in it and had no relation to its albuminous constituents. When the serum was deprived of its salts by dialysis, it was found that it reacted with uric acid and the urates like simple water; and no doubt the same rule holds good with regard to all the bodily fluids. An examination of the saline components of these fluids is therefore of prime importance in the study of the chemistry of gout. The serum of the blood and its derivatives, lymph and synovia, although differing considerably from each other in their albuminous elements, are almost identical in regard to both the quantity and the quality of their saline constituents. These latter are remarkable for the immense preponderance of sodium salts. The subjoined table exhibits the average proportion of the several saline ingredients contained in blood-serum.

TABLE XI.—Showing the Percentages of the several Salts in Blood-serum.

Sodium chloride .. ..	0.50 per cent.	} Sodium salts=0.73 per cent.
Sodium bicarbonate .. ..	0.20 per cent.	
Sodium phosphate .. ..	0.03 per cent.	
Potassium salts .. ..	0.06 per cent.	
Calcium salts	} .. 0.06 per cent.	} All other salts=0.11 per cent.
Magnesium salts		

The fact just mentioned—namely, that the reactions of uric acid and the urates with the bodily fluids depends exclusively on the saline ingredients contained in them—suggested the idea that advantage might be taken of this circumstance to facilitate the chemical study of gouty precipitation. If a solution in water of the salines of blood-serum were prepared, such a solution might be expected to behave with uric acid and the urates like the serum itself; and this proved on trial to be the case. An examination of the above table shows that the salts of sodium exceed the aggregate of all the other salts of blood-serum in the proportion of seven to one. Practically, for the purpose in view, the saline basis of blood-serum might be considered as consisting essentially of sodium chloride and sodium carbonate, so greatly do these preponderate over the sum of all the other salts put together. From these particulars it may be deduced that a solution in water containing chloride and bicarbonate of sodium in the proportion specified in the table would be a fairly exact representation of blood-serum, in so far as its saline ingredients are concerned. It was found experimentally that such a solution reacted with uric acid and the urates in the same manner as blood-serum itself and in the same manner as a solution comprising all the salines of the serum in their due proportions as ascertained by the best analyses. Accordingly a solution was prepared in conformity with these indications, and was designated as the *standard solvent* or *standard solution*. Its composition was as follows:

TABLE XII.—Showing the Composition of the Standard Solvent.

Sodium chloride .. ..	0.5 grammo.
Sodium bicarbonate .. ..	0.2 grammo.
Distilled water .. ..	100 cubic centimetres.

This solution was much used in the present research, especially as a pioneer. For experimental purposes it pos-

<sup>1</sup> The needles of sodium bi-urate are so minute and delicate that some of them pass through the filter unless the most stringent precautions are taken.

sessed certain advantages over serum and synovia. Its composition could be more easily modified by additions to or subtractions from it; the quantities of uric acid and urates taken up by it could be more exactly estimated; and its limpidity permitted the first signs of precipitation to be more readily detected. The behaviour of uric acid and the urates with this solvent was studied in detail under varying conditions of temperature and time and with varying modifications of its composition. The results thus obtained were afterwards collated with those obtained with blood-serum in similar circumstances and with parallel modifications of its composition. The standard solvent was found to behave with sodium bi-urate in exactly the same way as blood-serum. Only the minutest traces of the bi-urate were taken up by it at 100° F. Such a solution, when carefully filtered, gave no precipitate of uric acid when treated with hydrochloric acid.

(c) *Solubility of Sodium Bi-urate in Saline Solutions.*—The influence of different saline substances on the solubility of sodium bi-urate has not only a pathological but also a therapeutical bearing. Saline substances are largely used in the treatment of gout, both in the guise of pharmaceutical preparations and as constituents of mineral springs, under the belief that they promote the holding in solution of the peccant bi-urate, and thereby hinder its deposition as gouty concretions and even favour the resolution of concretions already formed. It is therefore of practical interest for us to know what kinds of salts (if any) act favourably, and what kinds act unfavourably, in this respect. A large series of experiments were undertaken with a view of elucidating this point and the deductions indicated are, I venture to think, of considerable interest. The salts of which the effects were investigated were those of sodium, potassium, calcium magnesium and ammonium. The experiments were carried out in the following manner: Solutions of known strength of the salts to be tested were prepared in distilled water. These solutions were digested at blood heat with excess of sodium bi-urate in corked flasks. The flasks were then placed in the warm chamber and maintained at 100° F. with frequent agitation for five hours. The supernatant liquid was then carefully filtered off. In some cases repeated filtration through a threefold filter was required in order to obtain a perfectly transparent product. Finally, the percentage of uric acid in the filtrate was estimated and calculated as sodium bi-urate. The results thus obtained are exhibited in the following tables. The solubility of the bi-urate in distilled water is placed at the head of each table as a standard of comparison.

*Salts of Sodium.*—The effects of the following soda salts were investigated—namely, the bicarbonate, chloride, sulphate, phosphate and salicylate. All these salts showed a powerful influence in diminishing the solvent power of the medium on the sodic bi-urate, and the adverse influence increased progressively up to a certain point with the increasing strength of the solution.

TABLE XIII.—Showing the Influence of Sodium Salts on the Solubility of Sodium Bi-urate, at 100° F.

0·3 " " " " " " " " " " " " " " " "	0'80 "
0·5 " " " " " " " " " " " " " " " "	0'25 "
0·1 " sodium phosphate (crystals) .. .. .	0'70 "
0·5 " " " " " " " " " " " " " " " "	0'82 "

\* The estimations in this and the following tables were generally made by the usual gravimetric process with hydrochloric acid. When the quantity dissolved was too small for weighing, it was estimated by a ninimetric adaptation of Arthaud and Butte's method.

The table indicates that the degree of alkalescence of the medium or its neutrality had not the slightest influence on the result. The carbonate and phosphate, which have an alkaline reaction, acted exactly in the same way as the chloride and sulphate, which have a neutral reaction. It may be observed that the sodium chloride had a more marked effect

than the other sodium salts—more than the carbonate, but especially more than the sulphate, phosphate and salicylate. This difference is, however, solely due to the larger percentage of the metal in the chloride. When solutions were prepared of these several salts in such proportion that the percentage of sodium in them was constant, their effect was found to be as nearly as possible equivalent.

*Salts of Potassium.*—Solutions of the following potassium salts were subjected to examination—namely, bicarbonate chloride, phosphate and sulphate. The results stand in the strongest contrast with those obtained with sodium salts.

TABLE XIV.—Showing the Influence of Potassium Salts on the Solubility of Sodium Bi-urate at 100° F.

Solvent.	Sodium bi-urate dissolved.
Water .. .. .	1'00 per 1000
Water containing:—	
0·1 per cent. potassium bicarbonate .. .. .	0'96 "
0·2 " " " " " " " " " " " " " " " "	1'00 "
0·3 " " " " " " " " " " " " " " " "	1'00 "
0·5 " " " " " " " " " " " " " " " "	0'97 "
0·7 " " " " " " " " " " " " " " " "	1'02 "
1·0 " " " " " " " " " " " " " " " "	0'98 "
0·1 " potassium chloride .. .. .	0'96 "
0·3 " " " " " " " " " " " " " " " "	1'01 "
0·5 " " " " " " " " " " " " " " " "	1'10 "
0·1 " potassium phosphate .. .. .	1'01 "
0·5 " " " " " " " " " " " " " " " "	1'00 "

The experiments tabulated indicate that the salts of potassium exercise no influence neither for nor against on the solubility of the bi-urate. The results came out, within the necessary limits of error, precisely as with distilled water. The bicarbonate and phosphate, which have an alkaline reaction, behaved exactly in the same way as the chloride, which has a neutral reaction. The varying strengths of the solutions made not the least difference.

The difference between solutions of sodium salts on the one hand and those of potassium salts and distilled water on the other is so conspicuous that it is easily perceived without any resort to quantitative analysis. A 0·7 per cent. solution of any of the sodium salts (reckoned as anhydrous) dissolves so little of the bi-urate that saturated solutions made at blood heat show no precipitation of uric acid when treated with hydrochloric acid, or at most only a few scattered crystals at the end of forty-eight hours; whereas similar solutions made with potassium salts, or with distilled water, become almost at once milky when treated with hydrochloric acid, and in a few minutes throw down an abundant deposit of uric acid.

*Calcium, Magnesium, and Ammonium Salts.*—The addition of calcium, magnesium, and ammonium salts diminished the solvent power of water on sodium bi-urate. The subjoined table exhibits the results obtained with these three classes of salts.

TABLE XV.—Showing the Influence of Calcium, Magnesium and Ammonium Salts on the Solubility of Sodium Bi-urate at 100° F.

Solvent.	Sodium bi-urate dissolved.
Water .. .. .	1'00 per 1000
Water containing:—	
0·1 per cent. calcium sulphate .. .. .	0'65 "
0·2 " " " " " " " " " " " " " " " "	0'44 "
0·5 " calcium chloride .. .. .	0'27 "
0·1 " magn. sulphate (crystals) .. .. .	0'90 "
0·1 " magnesium chloride .. .. .	0'85 "
0·5 " " " " " " " " " " " " " " " "	0'68 "
0·1 " ammonium chloride .. .. .	0'85 "
0·2 " " " " " " " " " " " " " " " "	0'60 "
0·3 " " " " " " " " " " " " " " " "	0'42 "
0·5 " " " " " " " " " " " " " " " "	0'25 "

The table shows that calcium salts exercise a strongly deterrent effect on the solvent power of water on sodium bi-urate, approaching in this respect but not equalling the sodium salts. The magnesium salts, on the other hand, although exhibiting a distinctly deterrent influence, approach more nearly to the indifferent reaction of the potassium salts. The salts of ammonium were found to stand in an intermediate position between those of calcium and magnesium.

Reviewing these results as a whole, the following conclusions may be deduced, in regard to the solubility of sodium bi-urate in simple saline solutions, at the temperature of the body:—(a) The influence of a salt depends exclusively on the nature of the base, and has no reference to the acidulous radicle with which the base is combined. (b) Salts with an alkaline reaction, such as carbonates and phosphates, do not differ in the least from neutral-reacting salts, such as chlorides and sulphates. (c) Salts of soda exercise a strong deterrent influence, and the deterrent influence increases with the increasing percentage of the salts in solution. Salts of

lime, magnesia and ammonia have also a deterrent effect, but slighter than that of salts of soda. Salts of potassium have no effect either way.

#### BEHAVIOUR OF URIC ACID WITH BLOOD-SERUM AND THE STANDARD SOLVENT AND WITH SYNOVIA.

An examination of the behaviour of free or uncombined uric acid with blood-serum and kindred media is a necessary part of the study of the chemistry of gout. It is only by knowledge thus gained that we can hope to elucidate the mode in which sodium bi-urate originates in the body, and learn something of the conditions which control its precipitation in the gouty system. The reactions of free uric acid with blood-serum and synovia and with the standard solvent and its modifications are of quite a different kind from those of sodium bi-urate with the same media. In the latter case there is simply an act of solution. The bi-urate is taken up substantially unchanged, and the questions we had to decide were as to its degrees of solubility in the several menstrua. But when free uric acid is brought into contact with blood-serum and kindred media, there occurs not merely an act of solution, but a series of chemical reactions. Uric acid first enters into combination with the bases contained in the media; these new compounds then pass into solution, and subsequently undergo certain ulterior changes which it is of much interest to follow.

*Behaviour of Uric Acid with Blood-serum and the Standard Solvent.*—When uric acid is digested at the temperature of the body with blood-serum or with the standard solvent it passes into solution in combination with a base. In the course of an hour, with due agitation, the liquids will, on analysis, be found to have taken up uric acid in the large proportion of about 1 part in 500. The chemical and solvent power of these media on uric acid depends on the sodium carbonate contained in them and not on the sodium chloride, for a solution of the latter salt alone has no more action on uric acid than pure water. On the other hand, a solution containing sodium bicarbonate alone has precisely the same action on uric acid as when it is associated, as in the serum and standard solvent, with sodium chloride. The question now arose, What is the combination in which uric acid enters into solution? It could not be bi-urate, because crystalline sodium bi-urate is almost insoluble in these media; nor could it be neutral urate, because the neutral urates cannot arise in the presence of carbonates. The presumption remained that the combination is a quadri-urate. It was, however, highly desirable to have direct proof. This was obtained by taking advantage of the great difference of solubility of quadri-urates at different temperatures. The following experiment appears to be conclusive on this point. Uric acid in excess was digested at blood heat with a 1 per cent. solution of sodium bicarbonate under constant agitation for twenty minutes. The filtered product was rapidly cooled on ice. It threw down a copious amorphous deposit, which when duly washed on the filter with rectified spirit to free it from adherent carbonate gave the characteristic reaction of quadri-urate—that is to say, it was decomposed by water with abundant emission of uric-acid crystals. A corresponding experiment with a 0.5 per cent. solution of potassium bicarbonate yielded exactly the same results.<sup>2</sup> We may therefore conclude with certainty that when uric acid comes into contact with blood-serum or the standard solvent it enters into solution in the first instance as a quadri-urate; but the process does not stop here. The quadri-urate gradually takes up an additional atom of base and is thereby converted into bi-urate and the bi-urate thus formed is, after some delay, eventually precipitated in the crystalline form.

In order to bring this remarkable succession of events more vividly before your minds I will relate the particulars of two actual experiments.

*Experiment 1.*—Uric acid in excess was digested, with frequent agitation, in the standard solvent at 100° F. for twenty minutes. The excess of uric acid was then filtered off and the clear solution was placed in a cork phial in the warm chamber. It remained unaltered for two days. On the third day it began to precipitate and on the fourth day a copious deposition of crystalline bi-urate took place. On the fifth day the process was completed and the supernatant liquor was found on acidulation to contain only traces of uric acid.

<sup>2</sup> Solutions of the common (di metallic) phosphates of soda and potash and of the alkaline acetates also take up uric acid very freely at blood heat and the combination formed in these cases in the first instance is likewise a quadri-urate as may be shown by the above-described method of cooling on ice.

*Experiment 2.*—Blood-serum of the horse was digested at 100° F. with excess of uric acid for fifteen minutes with constant agitation. It was then filtered and placed in a corked phial in the warm chamber. In about twelve hours the serum, previously clear, began to lose transparency and fine needles of bi-urate were detected in it with the microscope. On the next day copious precipitation took place. On the fourth day the process seemed to be completed and the supernatant serum was found to be almost free from uric acid. It was impossible not to be struck with a certain rough resemblance between the results observed in these experiments and the phenomena of the gouty paroxysm. In the gouty subject it is assumed that the blood becomes more and more impregnated with uric acid until, after a certain period of incubation has been accomplished, sudden precipitation of sodium bi-urate takes place in and about the joints, and the "fit of the gout" is declared. Then follows a process of recovery, with restoration of the blood to a purer state—that is, with a lessened impregnation of uric acid. In the artificial counterfeit we observe a similar succession of events. First, impregnation of the medium with sodium quadri-urate; secondly, a period of incubation or maturation, during which the quadri-urate passes into bi-urate; thirdly, somewhat sudden precipitation of sodium bi-urate in the crystalline form; and lastly, restoration of the medium to comparative purity.

*Behaviour of Uric Acid with Synovia.*—It is a marked peculiarity of the uratic phenomena of gout that the deposits occur most commonly in and about the joints; and it was a matter of interest in the present inquiry to ascertain how synovia behaved when impregnated with uric acid; and especially whether synovia, as compared with blood-serum and when impregnated to an equal degree, had the property of retarding or hastening the precipitation of bi-urate. This part of the investigation is hampered by the difficulty of obtaining an adequate supply of materials, and my information thereupon is scanty. I have so far only been able to make satisfactory experiments with synovial fluid drawn from the hip of the ox. From this source about a couple of ounces may be obtained from the two joints. Butchers tell me that the synovia from the hip is thinner as well as more abundant than that obtained from the other joints. On two occasions I was able to examine and compare the synovial fluid of the hip-joint with the blood-serum of the same ox. The behaviour of the two fluids with uric acid was substantially the same; but in both instances I found that, when impregnated with uric acid in an equal degree, precipitation of bi-urate began distinctly a little earlier in the synovia than in the serum. My impression is—but it is only an impression—that with the thicker and more concentrated synovia of the smaller joints this difference would be more pronounced. Whether there is in this distinction between serum and synovia a key to the preference of uratic deposition for the joints is a question well worthy of further inquiry. It is, at any rate, conceivable, supposing the blood and its derivative fluids to be equally impregnated with uric acid and supposing the synovial fluids to be more largely charged than their congeners with salts and especially with sodium salts, that precipitation of bi-urate would take place earlier and by preference in and about the joints than elsewhere. This point will be again touched on in my next lecture when I come to speak of the topographical distribution of uratic deposits.

#### GELATINOUS OR HYDRATED MODIFICATIONS OF THE URATES.

There is a point of considerable interest in connexion with the chemistry of the urates which may be conveniently considered in this place, and that is the occurrence of gelatinous modifications of these compounds, which differ both in physical condition and in solubility from the more common granular and crystalline forms. The existence of these gelatinous modifications was first noted by Dr. Ord in the course of his well-known researches on the influence of colloids upon crystalline form and cohesion.<sup>3</sup> He observed that when hot saturated solutions of the urates of soda or ammonia were mixed with an equal bulk of strong solutions of the alkaline chlorides or phosphates the urates were thrown down on cooling in a gelatinous state. He further observed that this condition was not a permanent one, and that the gelatinous matter, after a time, changed into a mass of crystals. The interest for us in our

<sup>3</sup> On the Influence of Colloids upon Crystalline Form and Cohesion, by W. M. Ord, London, 1879, pp. 72 et seq.

present inquiry of these observations lies in the probability that these gelatinous modifications of the urates intervene, perhaps importantly, in the succession of changes which lead up to the formation of uratic deposits in gout. I must therefore ask your attention to some additional particulars which I have gathered on this subject. Crystalline sodium bi-urate is very much more soluble in hot water than in cold water. Nevertheless, such a hot solution, fully saturated, does not deposit its surplus bi-urate on becoming cold; it continues perfectly clear and remains so. But if the solution be evaporated down on the water-bath the bi-urate is again recovered in the crystalline form. It is obvious, therefore, that the bi-urate in passing into hot solution undergoes some notable change whereby its solubility is greatly enhanced. This change consists in the assumption of the gelatinous modification, and herein lies the explanation of the enhanced solubility. These deductions are substantiated by the following experiment: Crystalline sodium bi-urate is dissolved to saturation in hot water. The filtered solution when cold is mixed with an equal volume of a 20 per cent. solution of common salt. A voluminous jelly-like precipitate is thrown down.<sup>4</sup> This is caught on a filter and allowed to drain, and then cautiously washed on the filter with cold water. The gelatinous bi-urate is thus obtained in a condition of approximate purity. Now when this substance is digested at 100° F. with blood-serum or with the standard solvent, it goes freely into solution—so freely that when the filtered product is treated with acetic acid it throws down on standing a considerable deposit of uric acid. But it has before been shown that these same media when digested under similar conditions with the crystalline sodium bi-urate take it up so sparingly that the filtered products do not yield any deposit of uric acid when acidulated.

Dr. Ord noticed, as above stated, that the gelatinous bi-urate collected as a mass on a filter passes after a time into the crystalline condition. The same transformation occurs when the gelatinous matter is held in solution in blood-serum or the standard solvent. Such solutions when set aside continue clear and unchanged for a certain time, but after the lapse of a day or two the bi-urate is reprecipitated in the crystalline form. The obvious explanation is this. The dissolved gelatinous modification reverts by slow degrees to the anhydrous crystalline condition and the bi-urate, in this condition is, as we know, almost insoluble in these media. Consequently, when the transformation reaches a certain point the bi-urate is necessarily precipitated. As to the nature of the gelatinous modifications of the urates, Dr. Ord is inclined to regard them as true colloids, and he remarks on their resemblance to the colloidal modifications of silica. Their jelly-like appearance is certainly strongly suggestive of this idea, but they differ radically from true colloids in passing with ease and unchanged through the dialyser. Their real nature is, I believe, that of hydrated salts. The crystalline bi-urates are anhydrous, the gelatinous modifications are highly hydrated. It is well known that certain salts can be obtained in several degrees of hydration and that these several hydrations possess diverse degrees of solubility. The quadri-urates likewise readily assume the gelatinous modification. Sodium quadri-urate may be obtained in the gelatinous state in the following manner. A 5 per cent. solution of the common phosphate of soda is heated to boiling with excess of uric acid. The mixture is filtered hot. On cooling the filtrate sets into a jelly. The gelatinous substance thus obtained, pressed between blotting paper to deprive it of its mother liquor, possesses the characteristic reaction of a quadri-urate—that is to say, it is rapidly decomposed by water with copious emission of uric-acid crystals.

*Summary of the History of Uric Acid in the Body: (a) in the Normal State, (b) in the Gouty State.*—The facts elicited in this and the preceding lectures enable us to obtain a coherent view of the state and destiny of uric acid in the body. It has been shown that in normal urine uric acid always exists as a quadri-urate; and that in animals which eliminate their nitrogen as uric acid, like birds and serpents, the urinary secretion is composed entirely of the same combination. Proof has also been furnished that in liquids containing alkaline carbonates—such as the serum of the blood and its derivatives, lymph and synovia—uric acid passes into solution in the first instance as a quadri-urate. From these considera-

tions it may be inferred that in the normal state uric acid is primarily taken up in the system as quadri-urate, that it circulates in the blood as a quadri-urate and that it is finally voided with the urine as a quadri-urate. In perfect health the elimination of the quadri-urate proceeds with sufficient speed and completeness to prevent any undue detention or any accumulation of it in the blood. But in the gouty state this tranquil process is interrupted, either from deficient action of the kidneys or from excessive introduction of urates into the circulation, or from some other cause, and the quadri-urate lingers unduly in the blood and accumulates therein. The detained quadri-urate, circulating in a medium which is rich in sodium carbonate, gradually takes up an additional atom of base and is thereby transformed into bi-urate. This transformation alters the physiological problem. The uric acid, or rather a portion of it, circulates no longer as the more soluble and presumably easily secreted quadri-urate, but as bi-urate, which is less soluble, and probably also—either for that reason or because it is a compound foreign to the normal economy—less easy of removal by the kidneys. The bi-urate thus produced exists at first in the gelatinous modification, but with the lapse of time and increasing accumulation it passes on into the almost insoluble crystalline condition and then precipitation becomes imminent, or actually takes place.

#### THE CONDITIONS WHICH ACCELERATE OR RETARD THE PROCESSES WHICH CULMINATE IN THE PRECIPITATION OF SODIUM BI-URATE.

Assuming a real analogy to exist between the processes which go on in serum artificially impregnated with uric acid and the processes which go on in the blood of a gouty patient and which culminate in the deposition of uratic concretions, it is a matter of interest, as bearing on the pathology and treatment of gout, to investigate the conditions which, in the artificial parallel, accelerate or retard these processes. As already explained, these processes consist of three distinct chemical changes. First, the quadri-urate originally formed is converted into hydrated bi-urate; next the hydrated bi-urate is changed into anhydrous bi-urate; and finally this anhydrous bi-urate is precipitated in the crystalline form. For the present purpose it will be more convenient to consider these changes as one continuous process; and for the sake of brevity and ease of expression this process may be designated as "maturation." The investigation embraced a study of the effects of temperature, percentage of uric acid in solution and the addition of various saline and other substances to the maturing medium.

(a) *Temperature.*—It was found invariably that the stage of maturation was more quickly accomplished in the warm chamber at 100° F. than at the temperature of the room, but the ultimate result was exactly the same in both cases. For example, serum charged with 1 part uric acid in 600 began to precipitate in the warm chamber in four hours and precipitated copiously in six hours. A duplicate specimen kept at the temperature of the room (65° F.) began to precipitate in eight hours and did not precipitate copiously for sixteen hours. Another sample of serum, impregnated with 1 part of uric acid in 1000, began to precipitate in the warm chamber in six hours and deposited copiously in fourteen hours; while a duplicate kept at the temperature of the room (60° to 70° F.) only began to precipitate in thirty hours and copious precipitation did not take place for forty-eight hours. The absolute constancy of these results led to the idea that maturation would go on more rapidly at a febrile temperature (104° to 105° F.) than at the normal temperature of the body, and that herein might be found an explanation of the circumstance that gouty outbreaks sometimes follow immediately on the heels of an injury. When, however, this notion was tested experimentally no support was found for it. It was also conceived that, although maturation itself was favoured by warmth, the terminal act of the process—namely, the act of precipitation—might, on the contrary, seeing that the bi-urate is more soluble at higher than at lower temperatures, be favoured by cold and that this might account for the fact that gouty concretions tend to be deposited in the cooler and more exposed parts of the body, in the joints and subcutaneous tissues rather than in the warmer interior regions. I failed, however, to obtain any direct experimental evidence in favour of this conception.

(b) *Quantity of Uric Acid in Solution.*—It was found that no condition exercised so great and decisive an influence on the speed of maturation and the advent of precipitation as

<sup>4</sup> The gelatinous bi-urates may be thrown out of their solutions in several ways. Instead of common salt a concentrated solution of the phosphate, chloride or acetate of sodium, potassium or ammonium may be used, or any of these salts in crystals may be added to saturation to the solution.

the proportion of uric acid in solution. The following experiment with blood-serum, the results of which are arranged in a tabular form, illustrates these points in a striking manner. The phials containing the serum were placed in the warm chamber for fourteen days and were afterwards kept at the temperature of the room. Chloroform was added to prevent putrefactive changes:—

TABLE XVII.—Showing the Influence of Percentage of Uric Acid in the Medium on the Speed of Maturation, and the Time of Advent of Precipitation.

Quantity of uric acid contained in the serum.	Time of precipitation of sodium bi-urate.
1 in 1000 .. .. .	Precipitation began in 6 hours; copious precipitation in 14 hours.
1 in 2000 .. .. .	Precipitation began in 38 hours; copious precipitation in 8 days.
1 in 3000 .. .. .	Slight precipitation began in 3 days, which became a little more copious in 12 days.
1 in 4000 .. .. .	A few needles of bi-urate were detected on the 6th day; more needles and a few tufts in 12 days.
1 in 5000 .. .. .	A few short needles were detected on the 13th day. In 80 days the needles were somewhat more numerous.
1 in 6000 .. .. .	No needles were discoverable in 14 days; a few were detected in 40 days.
1 in 8000 .. .. .	No needles could be detected after the lapse of 40 days.

Assuming that the inflammatory arthritic attacks in gout are directly due to copious and sudden precipitation of crystalline stars and needles of sodic bi-urate in the cartilages and fibrous structures of the joints, the evidence before me indicates that such copious sudden precipitation can only take place when the fluids bathing these structures are impregnated with uric acid in at least the proportion of 1 part in 2500. Below this point the precipitation occurs slowly and scantily, and only in the form of short scattered needles. When the proportion of uric acid in the serum was only 1 part in 5000 the deposited needles were mostly about as long as the diameter of a red blood-disc, some were twice this length, and a few three times this length, and all were of extreme tenuity. It is quite conceivable that this slighter precipitation in the tissues of short scattered needles might account for certain irritations in the various organs, such as characterise irregular or larval gout; but it could scarcely engender downright inflammatory attacks. It is further conceivable that the presence in the blood of such scattered needles might constitute foci, around which clotting might take place; and that the thrombosis not unfrequently observed in gouty cases might thus be accounted for. The impregnation of the blood in gouty persons with uric acid to the extent of these lesser degrees is within the range of observed actualities. Sir Alfred Garrod obtained by quantitative analysis from the blood-serum of one of his patients uric acid to the amount of 1 part in 5714; and he remarks that the quantities thus recoverable from the blood are probably much under the actual amounts, as considerable loss is liable to occur from unavoidable causes. These considerations lead to the suggestion that a microscopical examination of the blood in gouty persons might sometimes reveal the existence of needles of bi-urate in that fluid. I tested this point in ten cases of chronic gout by examining a drop of blood drawn from the finger, but I failed to obtain positive results.

(c) *Influence of Saline Substances.*—The effect of saline substances on the maturing process was tested by adding small quantities of various salts to serum impregnated with uric acid and observing whether these additions accelerated or retarded precipitation. The experiments were carried out in the following manner: Uric acid was dissolved at blood heat in blood-serum in the proportion of 1 per 1000 or 1 per 2000. A number of phials capable of holding 25 cc. were charged with the serum thus impregnated. One phial had no further addition made to it—this was the control phial. To the others small quantities, varying from 0.05 per cent. to 0.2 per cent. of the salts to be tested, were added. The phials were then chloroformed to prevent decomposition and placed in the warm chamber. The occurrence of precipitation was noted at two points—namely, at its very onset, as revealed by the detection on microscopical examination of needles of bi-urate, and secondly, when precipitation became copious and was recognisable by the naked eye. A large number of experiments were made on this plan. The state of the medium during precipitation was that of a supersaturated solution, and, consequently a very slight, often inappreciable, inequality in the

conditions of the experiment was sufficient to disturb the time and rate of precipitation. For this reason it was frequently found necessary to repeat the observations once and again to get the correct indication. I need not trouble you with details; the following summary indicates sufficiently the conclusions deduced from the experiments. The addition of sodium salts to the maturing medium hastened precipitation. An idea of the degree of acceleration may be gathered from the following examples. Serum impregnated with uric acid to the extent of 1 part per 1000 commenced to precipitate in seven hours and precipitated copiously in sixteen hours. A parallel experiment, in which 0.2 per cent. of sodium chloride had been added to the serum, began to precipitate in five hours, and precipitated copiously in twelve hours. Another sample of serum was impregnated with uric acid to the extent of 1 part in 2000. This began to deposit crystals in thirty hours, and deposited freely in ninety-six hours. In a parallel experiment, in which 0.2 per cent. of sodium bicarbonate had been added to the medium, precipitation began in twenty hours and free precipitation took place in forty hours. The alkaline reacting salts, the carbonate and phosphate, had exactly the same effect as the chloride and sulphate, which are neutral in reaction.

The addition of potassium salts sensibly retarded precipitation, but did not appreciably diminish the eventual amount of it. Here, again, the carbonate and phosphate, which are alkaline, produced just the same effects as the chloride, iodide and bromide, which are neutral. Both with potassium and sodium salts the results were entirely dominated by the nature and quantity of the bases added and had no reference to the acidulous radicle with which the bases were combined.

The addition of calcium and magnesium salts appeared to delay precipitation, but their action in this respect was quite insignificant or even doubtful.

## ABSTRACT OF THE Huntarian Lectures ON CERTAIN DISEASES OF THE BREAST,

*Delivered at the Royal College of Surgeons*

By H. BETHAM ROBINSON, M.S., M.D. LOND.,  
F.R.C.S. ENG.,

HUNTARIAN PROFESSOR OF SURGERY AND PATHOLOGY, ROYAL COLLEGE OF SURGEONS; ASSISTANT SURGEON TO THE EAST LONDON HOSPITAL FOR CHILDREN, SHALWELL; DEMONSTRATOR OF ANATOMY AT, AND LATE RESIDENT ASSISTANT SURGEON TO, ST. THOMAS'S HOSPITAL.

### LECTURE III.

IN this lecture the growths affecting the ducts of the breast are described under a classification neither strictly clinical nor pathological.

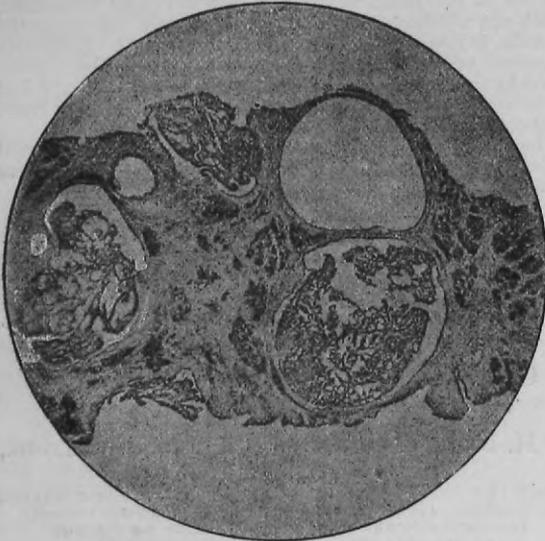

*Duct papilloma* is characterised by the development of papillary growths in the larger ducts, usually in the region of the nipple and particularly in the sinuses. There is no nipple retraction or enlargement of the axillary glands. Discharge from the nipple, which may be serous, clear, or bloodstained, or pure blood, is a marked feature, but it is rarely persistent. The growth is unilateral, unaccompanied as a rule by pain or tenderness, and its progress is slow. It is met with in both married and single from thirty-five to fifty-five. The discharge from the nipple may precede any swelling by some considerable period. There may be a history of prolonged suckling, sore nipples, or injury. On incising the swelling we have a space with smooth walls almost completely filled by a raspberry-like soft papilloma, attached by a slender pedicle. These papillomata may be single or multiple, usually the latter. (Fig. 1.) Of these, one alone may be large and they seem generally distributed in one duct area, of which the ducts may be dilated.<sup>1</sup> The following is an illustrative case: "S. S.—, thirty-nine, was admitted under the care of Mr. Clutton, in September, 1890. She was married and had three children, the youngest fifteen months old and allowed

<sup>1</sup> Barker: Brit. Med. Jour., vol. i. 1890.

to suckle for thirteen months. She had had cracked nipples, but no injury. On admission there was a lobulated and fluctuating lump just above and to the inner side of the left nipple, which was not retracted; this was first noticed three and a half years before, accompanied by a blood-stained nipple discharge and had grown without pain. The axillary glands were not enlarged. The right breast was healthy. On removal the small cyst contained a soft, purplish, villous papilloma growing from its deep surface and almost filling it, bathed by a yellow serous fluid; the growth was easily detached. The breast tissue around was indurated and embedded in it were small cystic spaces containing greyish growths. The nipple was not removed. In about three months there was a reappearance of thickening at the base of the nipple, accompanied by some discharge. The nipple and all the diseased tissue were removed and since this time, for one year and a half, the patient has remained quite well.<sup>2</sup> Rarely the warty growths may project from the mouths of the ducts on the surface of the nipple looking like granulomata.<sup>2</sup>

The papillomata are adeno-fibromatous in structure, composed of a delicate fibrous tissue basis on which are arranged one or more layers of epithelial cells, the deepest being

FIG. 1.

columnar in type. This connective tissue shows no cell infiltration. The cystic spaces are seen to be dilated ducts lined by cubical or short columnar epithelium continuous with the cells covering the papillomata. Specimen 4765 in the Hunterian Museum of the Royal College of Surgeons shows warty growths in enlarged ducts; at the exit of the chief dilated duct from the nipple there is seen to be a very definite constriction. In the case of S. S.— before quoted just beneath the surface epithelium of the nipple was noticed a small cavity filled with granular material. Below this the ducts passing down the nipple were dilated with small warty projections into their interior and the glandular substance in a few spots seemed cystic. From these specimens the change in the ducts appears to be a generalised one and the papilloma only an overgrowth at a special spot of the changed duct surface. Is this alteration due to some obstruction at the nipple surface leading to dilatation and papillary formations behind this, as may happen with strictures elsewhere, or does the change occur in relation with the chronic irritation induced by prolonged suckling, or is the introduction of some irritant, mechanical or microparasite, the causal agent? To assume any of these is mere speculation, but the latter lends itself to our consideration when we remember analogous changes produced by such factors.

The diagnosis of these cases, from the discharge with thickening in the nipple region and no enlarged glands, is comparatively easy. The prognosis is good after removal of the diseased area if it is freely done. If only a small segment be excised, it is possible that some of the dilated ducts may

be left behind, leading to reappearance of the growth. The affected area should be removed well into the base of the nipple for the same reason, if the latter be saved. The whole breast need not be taken away except in the cases where the papillomata are multiple and are not distributed in the same duct area. Many cases are recorded<sup>3</sup> of permanent cure and in no instance can I find a report of a recurrence of this condition as a carcinoma.

*Duct carcinoma* has been described under a great many names. Billroth,<sup>4</sup> in discussing the forms of adenoma, makes a soft variety, the cystadenoma, which corresponds to the softer type of duct cancer. Cornil and Ranvier<sup>5</sup> were among the earliest pathologists to endow this disease with a specific name, calling it "carcinôme vilieux," and to the French we are specially indebted for variation in the terminology. Delbet<sup>6</sup> names these growths "dendritic epitheliomas," Castex "cylindrical epitheliomas," and Labbé and Coyne "intra-canalicular epitheliomas." Neumann,<sup>7</sup> in Virchow's Archives, refers to the disease as "encysted medullary carcinoma," and Waldeyer,<sup>8</sup> in the same work, mentions tumours arising from the lactiferous ducts to which he gave the name of "fibro-carcinoma cysticum mammae." The simplest type of the disease has the papillary form, resembling the innocent growth before described, but with associates indicating malignancy. Clinically these papillary forms are not to be differentiated with any certainty from a firmer variety of tumours; histologically there may be great variation. There is in both cases a localised tumour, usually under the areola. It is not essential that they should be in the nipple region, some occurring towards the periphery of the gland. These growths are circumscribed and somewhat oval in shape. They are usually elastic, especially in the papillary form, where a cystic space has become more or less solid from outgrowths into its interior. The skin is quite free and the nipple is not retracted. Discharge is unusual, but in cases where the growth is very soft a blow or pressure may be followed by a bloodstained discharge. The cases recorded show that the outer half of the gland is more often affected. As a rule these tumours develop without pain; in a few cases it may be slight, but it never seems to be severe. Tenderness may be present. There is so little discomfort that advice is not sought for some time; of thirteen cases one had been present for three years, another two years, and the rest between a year and a half and three months. The disease affects elderly women; more than half are between forty and fifty, some are over that age, but it is rare to get them in quite young women. Bowlby<sup>9</sup> records a case at twenty-nine with a history of five months' growth. It is met with in married and single in about equal proportions and it is rarely seen in males.<sup>10</sup> These tumours are usually encapsuled. On section the papillary form may be very friable and appear granular. They are soft, do not cup on section, and are of a rosy colour, unless hæmorrhage has occurred, which is very frequent in these soft growths. Then they have a brown or black appearance, which in many instances has caused its nature to be considered as a melanotic sarcoma. Besides the bloodstaining these essentially villous tumours may have a gelatinous look from mucoid changes in the growth.<sup>11</sup> The firmer forms are not so friable and are of a greyish or reddish colour; they have been mistaken for encapsuled vascular sarcomata. In size the tumours vary from quite small nodules up to that of a hen's egg. In the true villous form it may be found that the lumps are multiple and distributed in one duct area. Encapsulation is not a constant feature. In some cases with quite a small growth infiltration may be detected in the fat around without, clinically, there being any other evidence of malignancy,<sup>12</sup> but as a rule this infiltration does not take place until at quite an advanced stage. The axillary glands are not involved early. The hæmorrhage in relation with these growths may be of so marked a character as to form cystic swellings filled with blood and to them the term "blood cyst" has been applied.<sup>13</sup> Masterman<sup>14</sup> describes a case under the name

"hæmorrhagic carcinoma" which, from the history and description, seems to be undoubtedly a villous cancer with hæmorrhage. Hæmorrhage, in the firmer form of these tumours, is not so common; if present, it may complicate the diagnosis.<sup>15</sup>

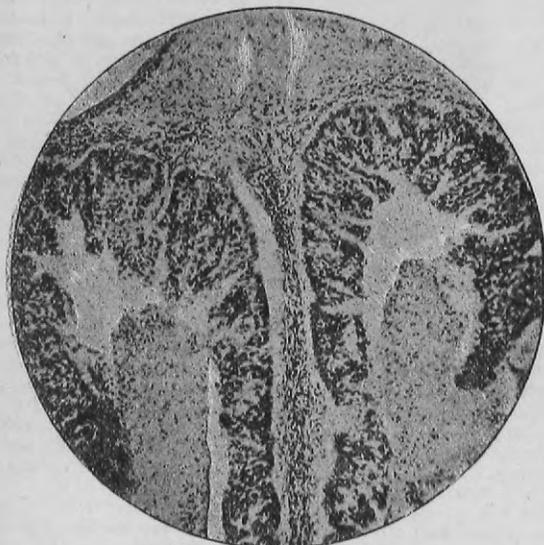

Histologically, in the soft forms distinct papillæ are seen to pass into the interior of a cavity; these have secondary offshoots, which interlock in filling up the space. These

FIG. 2.

papillary processes have an epithelial covering two or three layers in thickness, the deeper cells being typically columnar or cubical. These cells are arranged on delicate connective-tissue processes, which show such a scanty round-celled infiltration in many cases as to give doubts of the malignancy of the growth. (Fig. 2.) The surface cells very soon undergo mucoid degeneration, the latter material staining with hæmatoxylene a reddish colour, like that met with in ovarian adenomata; this mucus holds in suspension numerous epithelial cells

FIG. 3.

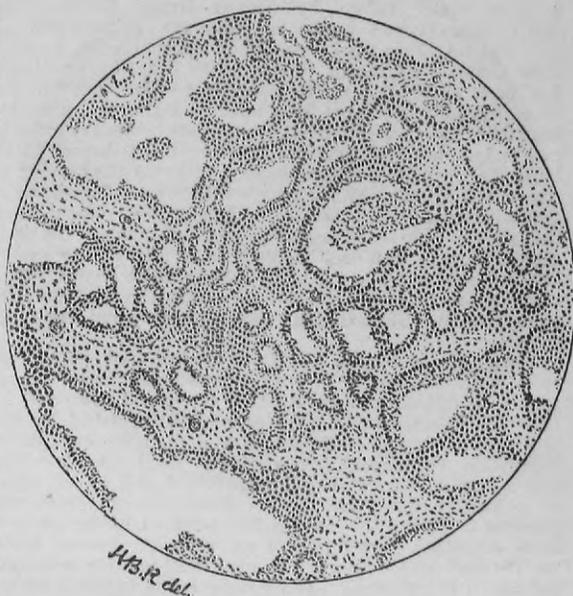

and blood discs. The connective tissue rarely appears in places to have undergone a mucoid change, as in carcinoma myxomatodes, and there may be hæmorrhage into it. Besides the more or less solid growths we may have evidence in the breast tissue around of cystic change due to dilatation of ducts in association with chronic interstitial mastitis. In this tissue

<sup>15</sup> Butlin: *Trans. Path. Soc.*, vol. xxxviii.

we may be able to trace all stages in the evolution of the growth from a multiplying epithelium to the formation of well-marked papillary processes and it seems consistent to assume that the growth has developed on the top of a chronic inflammation. In some cases again the papillary processes may be so united as to give the growths a trabeculated appearance. In the firmer forms the structure may be trabecular or may show alveolar spaces lined by an epithelium many layers in thickness, the outermost cells being columnar. The innermost layer of this epithelium tends to become papillated and in the centre may be granular debris. (Fig. 3.) The alveolar spaces in some examples may be filled by epithelial cells resembling a very cellular acinous carcinoma, except that the peripheral cells are columnar.

The course of these tumours is slow, extending over many years. R. Williams<sup>16</sup> groups the cases of duct papilloma and villous carcinoma together and says, "These growths are of a perfectly innocent nature, though often multiple; they have no tendency to local infection, nor do they ever disseminate in the adjacent lymphatic glands or the system at large and when completely removed they never recur." This very favourable prognosis is unfortunately not borne out by facts, for we have well-marked examples where the growth has recurred near the scar and where the glands have become involved. Bowlby<sup>17</sup> describes a case of villous

FIG. 4.

cancer where there were two recurrences: one two years and a half after the first operation and the other ten months later. One of my cases<sup>18</sup> had a local recurrence fifteen months after and the glands became involved within the next six months, or four years and a half after the tumour was first noticed. Butlin<sup>19</sup> quotes a case in which there were five local recurrences and involvement of glands ten years after the growth was first seen. I cannot find the record of any secondary growths in bones or viscera in this group. The treatment in these cases should be free removal at the earliest opportunity, with exploration of the axilla.

The next variety of duct cancer differs from the last group in its marked likeness to scirrhus. These tumours occur between forty and fifty years of age, attacking both single and married, the latter being very often sterile. They are hard, non-elastic and bossy on the surface, with ill-defined margins infiltrating into the tissues around. They are not limited especially to the nipple region. There is a distinct tendency for the skin to be implicated and in some cases it may be reddened. The nipple is not retracted and there is no discharge, but the axillary glands may be involved. Pain is a fairly constant feature, but it does not occur until late. The tumours are single and may have fluctuating spots in them

<sup>16</sup> THE LANCET, vol. i, 1892, p. 860.

<sup>17</sup> St. Bartholomew's Hospital Reports, vol. xxiv.

<sup>18</sup> *Trans. Path. Soc.*, vol. xli.

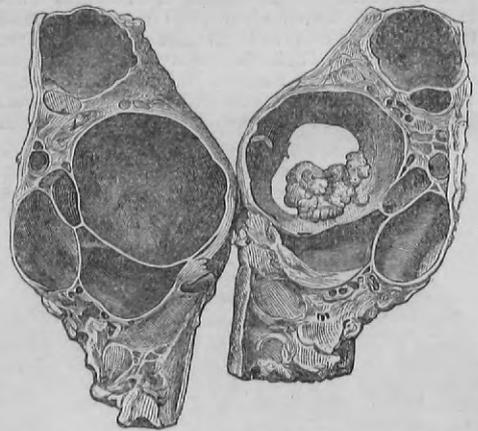

<sup>19</sup> *Ibid.*, vol. xxxviii.

from the presence of cysts. Their growth is slow, causing little inconvenience. Not only are these growths not to be distinguished clinically from scirrhus, but on section there may be some difficulty. They have a firm appearance, greyish red in colour, but they do not have the "unripe pear" look, nor do they cup on section. Hæmorrhage does not usually occur. The tissues around the tumours give evidence of chronic inflammatory change. Under the microscope these growths have a tubular structure, lined by, in most places, a single layer of columnar epithelium; many of the tubes are considerably dilated, so as to form cystic spaces.<sup>20</sup> (Fig. 4.) The latter, from the proliferation of their lining cells, may be converted into solid nodules, resembling a form of growth figured by Labbé and Coyne.<sup>21</sup> In some cases around these tubes may be seen great thickening of the basement membrane, which has been noted by Thin.<sup>22</sup> The diagnostic points between these growths and scirrhus are very slender, the chief clinical features in the former being the absence of nipple retraction and discharge and the slow rate of growth. These tumours tend to involve glands, but this does not apparently take place until the primary growth has been in existence for some time. There may be secondary deposits elsewhere, but of these very little is known. Shattock<sup>23</sup> has described a specimen in St. Thomas's Hospital, where there were tumours of a porous nature in connexion with two ribs. This was obtained from a woman of sixty, whose left breast had been amputated a few weeks before by Joseph Henry Green. The rib tumour proved to be a columnar epithelioma. I can find no other case recorded of dissemination in man. That tumours analogous to this occur in the lower animals has been shown by W. G. Spencer,<sup>24</sup> where many of the mammary glands of a cat were affected by hard infiltrating growths simulating scirrhus. There were secondary growths in the lymphatic glands and lungs and the tumour histologically proved to be a duct cancer. Should the tumour be removed, with the axillary glands if they are enlarged, there seems to be a lengthy period of immunity—at present, from the cases seen, it is impossible to speak of a cure. In three typical cases sixteen months, nineteen months and two years and a half have elapsed since removal and from a recent examination of all of them there is not the slightest sign of recurrence. The treatment should be early and free extirpation.

*Duct adenomas and carcinomas associated with duct cysts.*—In the second lecture I considered certain cysts formed by dilatation of the ducts of the gland described by Birkett<sup>25</sup> as duct cysts. These are distinguished by the presence of a clear discharge, the fluid in consistence being thin or mucoid. Now if the fluid be of a different nature, brownish or blood-stained, this is indicative of a further development, the formation of intra-cystic growths. These cysts with a bloodstained discharge have been described by Velpeau<sup>26</sup> as sero-sanguineous cysts. To Brodie<sup>27</sup> and Bryant<sup>28</sup> we are indebted for excellent papers on this disease. It must be borne in mind that a brown-coloured discharge is not necessarily in relation with the development of a cyst growth, although such is very probable. It may be derived from a very vascular cyst wall, either from a blow or in association with menstruation. A discharge of pure blood is a certain indication of the presence of vegetations. On opening these cysts we find that the intra-cystic growths occur in two forms, as pedunculated tumours, single or multiple, or as sessile nodular tumours. The first resemble the duct papillomata. As far as the pathology and some of the clinical signs are concerned, we can practically make no distinction between the two; the duct cysts may exist for a considerable period without the origin of any growth, and when the latter does develop it bears a very small proportion to the cystic cavity; whereas the duct papillomata are associated with a generalised duct change and the cavities are not large, not exceeding in most instances the papillary growth, but only developing *pari passu* with it. These points of difference, although small, I think are quite definite between duct-cyst adenomata and duct papillomata. These pedunculated duct adenomata may be

multiple and their prognosis appears to be favourable. I cannot find in recorded cases any evidence of recurrence where such a polypoid growth has been removed; and, on the other hand, the after-history of many states that four, five, or six years have elapsed with immunity. The sessile nodular growths have a broad base of attachment to the cyst wall and fill up a small part of its cavity. These solid masses are of a greyish or yellow colour, or black on the surface from hæmorrhage. Although the cysts may be multiple, the growths may only occur in one of them. The fluid in the cysts often contains cholesterol. The vegetations on section appear adenomatous and there is a marked tendency for the growth to extend outside the cyst wall into the tissues around. The very presence of such vegetations is sufficient reason for extirpation without any further evidence. If the tumour should prove malignant the glands are not implicated for some considerable time, thus early removal may mean very small probability of recurrence. The following is a very typical case: "J. E.—, forty-seven, was admitted under the care of Mr. Clutton in September, 1890. She was married and had had four children. Ten years before there was a clear, oily nipple discharge, followed by a small swelling one year after, just to the inner side of the right nipple. This swelling grew painlessly till one year before admission, when, after a blow, it doubled its size and got hard and the discharge stopped. The latter reappeared six months later and a few weeks after was blood-stained. The nipple became retracted and other swellings developed in the neighbourhood of the first. On admission there was a large lump on the inner side, occupying about half the breast, with the skin stretched over it, but at no spot adherent. It seemed chiefly cystic, but solid growth could be detected. There were no enlarged glands. The left breast was normal. After removal the cysts contained a brownish fluid with cholesterol. The tumour was much stained from hæmatoidin. The largest cyst had a sessile nodular growth adenomatous in look (Fig. 5), which extended

FIG. 5.

into the tissue outside the cyst; the smaller cysts were free. The intra-cystic growth was made up of dendritic processes, having a delicate fibrous framework, with a single layer of epithelial cells on it. (Fig. 6.) The growth infiltrating outside the cyst was tubular, with very scanty cell growth in the connective tissue. There has been no recurrence up to date." Specimens 4757 and 4759 in the Hunterian Museum are good examples of these nodular sessile growths. Bryant<sup>29</sup> quotes good examples of these cysts and growths showing their malignancy. Among them is the following case: "A woman of forty, married, had had a lump in the outer half of the breast for ten years, with bloody discharge. After removal she remained well till the axillary glands became involved two years and a half after. Two years later she died with tumours in the left humerus, left femur, os innominatum and vertebræ and also in the liver."

The malignant disease, then, may be implanted on these duct cysts. With its advent there may be pain and nipple retraction and the skin may become involved. The disease runs a slower course and the glands are not so frequently or

early involved as in a scirrhus. If we have diagnosed a duct cyst with vegetations the cyst should be first incised. If the tumour is pedunculated a local removal may suffice, the cyst wall from which it springs and some of the surrounding tissue. Should the growth be nodular, although there may be no signs of evidence of carcinoma, yet it should be viewed with suspicion and complete removal of the gland is to be advocated.

*Duct Cancer with Paget's Disease.*—A certain number of the cases of chronic eczema are associated with a tumour in the breast. Bowlby,<sup>30</sup> out of twenty-three collected cases, found tumours in fourteen and Delbet's<sup>31</sup> list shows seventeen out of twenty-six. The breast tumours succeed the eczema at a varying interval. What is the nature of the growth in relation with the eczema? Bowlby<sup>32</sup> says "in all these cases the new growth has run the usual course of a scirrhus and has been found on clinical examination to present the usual characters of this tumour"; and "with regard to the cancerous growth, all observers, with the exception of Dr. Thin, describe the tumours as scirrhus or spheroidal-celled carcinoma." He<sup>33</sup> gives the following description: "The tumour consisted of round masses of cells in an alveolar framework, with very little cell exudation and no appearance of small cell columns, as in scirrhus; the central cells are broken down and the outer cells are columnar." Barling<sup>34</sup> records a case of eczema of six months' duration where the nipple alone was affected and from it a cord

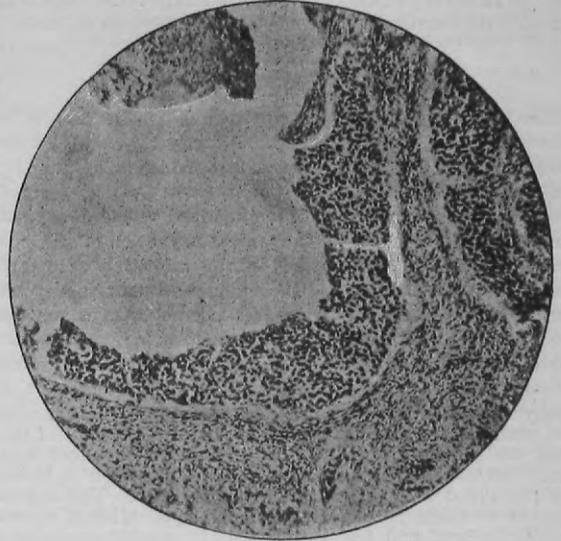

FIG. 6.

presented the forms in the epithelium described by Darier and Wickham as coccidia. This tumour recurred eighteen months after, with marked enlargement of axillary glands."

If there is any truth in the view that psorosperms are the cause of Paget's disease, it seems reasonable to suppose that if the disease has a growth in a breast it is due to the same cause. In passing along the ducts it is probable that some change would be produced here and such seems to have occurred, the tumour formed resembling duct cancers.

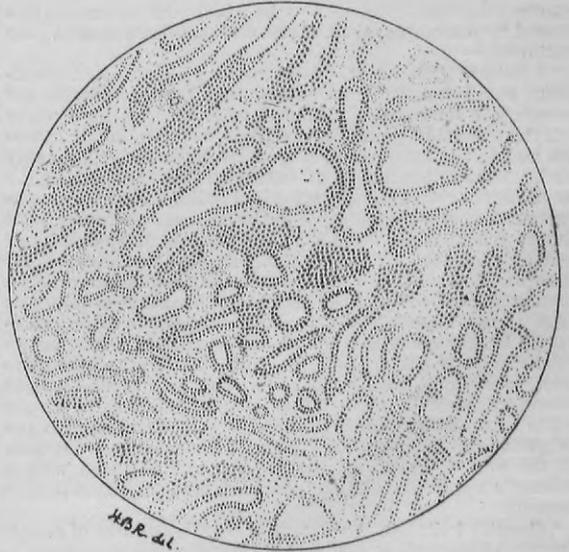

FIG. 7.

A point that has been urged against these tumours being allied to the duct carcinomata is that the latter are usually soft and the glands are not involved. This argument we know is not tenable after a consideration of the clinical course of the firmer duct tumours.

In quite an early stage of the eczema the structure of the

FIG. 8.

stretched to a nodule in the breast the size of a horse-bean. This on incision was of a yellow colour and appeared like an alveolar carcinoma, though in places it resembled a duct carcinoma. Jonathan Hutchinson, jun.,<sup>35</sup> remarks on the resemblance histologically to duct cancer.

The following tumour implanted on a chronic eczema was an undoubted duct carcinoma resembling the structure of the firm circumscribed tumours before described:—"M. G—, aged sixty and married. Soreness and discharge from the left nipple for two years. Four months before admission noticed circumscribed near nipple which was painless. The tissue between nipple and tumour seemed free. One gland in axilla. The tumour on section was made up of a number of cystic spaces filled with filings of epithelium very easily detached. (Fig. 7.) Histologically these large spaces are lined by a many-layered epithelium the deep cells of which are columnar. In the centre there is a large amount of granular material. The tissue between the tumour and nipple showed dilated ducts with proliferating epithelium and some small-celled exudation around. The skin

nipple may show very marked changes. The ducts have their epithelial lining proliferating and they are dilated. (Fig. 8.) This condition I found in a man of fifty-six<sup>36</sup> and it had given him no inconvenience. The case had additional interest because the patient had a very advanced carcinoma of the tongue.

AN ABSTRACT OF

Lectures

ON THE

TREATMENT OF SURGICAL  
TUBERCULAR DISEASES.*Delivered at the Royal College of Surgeons of England  
in June, 1892,*

By WATSON CHEYNE, M.B. ED., F.R.C.S. ENG.,

HUNTERIAN PROFESSOR, JOINT PROFESSOR OF SURGERY AT KING'S  
COLLEGE, SURGEON TO KING'S COLLEGE HOSPITAL, ETC.

## LECTURES II. &amp; III.

MR. WATSON CHEYNE illustrated the value of extension in tubercular disease of the spine with paralysis. The chronic inflammation of the bone in cases of spinal disease is kept up by the presence of the tubercle, by the weight of the upper part of the body and by the pressure of the inflamed vertebræ against each other as the result of the tonic contraction of the surrounding muscles. This chronic inflammation may extend to the meninges, leading to thickening and paralysis from pressure. In other cases these thickened meninges become infiltrated with tubercular tissue or a chronic abscess forms in the vertebral canal, both of these conditions also leading to pressure on the cord and paralysis. This condition of pachymeningitis is kept up to a great extent in unison with the osseous inflammation by the action of the weight of the body and of the muscular contraction, and therefore it is clear that the first indication as regards treatment is to see what can be done by relieving these conditions. This is best done by complete recumbency and the application of extension to the head and feet rather than by having immediate recourse to laminectomy. The effect of the muscular contraction in producing curvature and leading to the extension of the disease is not sufficiently realised and hence it has been thought by some that the object of the double extension is to undo the curvature, on the supposition that the paralysis was due to actual pressure of the bone. This is, however, not the case; the object of the extension is to overcome the muscular contraction and thus lead to diminution of the inflammation and absorption of the inflammatory material and consequently to relief of the pressure on the cord. The lecturer mentioned three cases in which the operation was avoided by the employment of rest and double extension. He continued:—

“I believe that most cases would yield to that treatment, but I am far from saying that laminectomy is not necessary in some cases. What I wish to urge, however, is that the operation should not be performed till double extension and rest in the recumbent posture have been thoroughly tried. The same principle of extension first followed by the use of proper retentive apparatus is, I believe, the best routine treatment wherever applicable in the case of tubercular joint disease where there is either superficial or deep disease of bone as evidenced by fixation &c. In hip-joint disease, for example, it is, I think, too much the fashion to order a Thomas's splint and let the patient get about on crutches at once. I quite admit that it is almost impossible to do otherwise in hospital practice, but when the patient can be put to bed for six or eight weeks I am sure it is best, where there are signs of bone trouble, to begin with treatment by light extension, generally three or four pounds, reducing the weight as the muscular resistance diminishes. In this way also the deformity can be most quickly and satisfactorily overcome. At the end of that time the patient can be fitted with a Thomas's splint so modified as to overcome the adduction properly.

“Counter-irritation is a favourite remedy in cases of simple chronic inflammation and was formerly much employed in tubercular disease, but now, under the erroneous idea that the only object of local treatment in these cases is to act directly on the tubercular tissue, it is falling into disuse. As I am trying to show, however, a great deal can be done in these cases by getting rid of the attendant chronic inflammation, and for this purpose the severest forms of counter-irritation—blisters and the actual cautery—are of value in suitable instances. In cases of pure synovial disease improvement

sometimes follows blistering, but where the bone is inflamed, and is deep-seated the most effectual method is the application of the actual cautery. The most suitable parts for this treatment are the hip and shoulder joints and the spine. I have not seen much good result from the use of the cautery in pure synovial disease and in the case of superficial joints, such as the knee, I should fear that it would do harm by increasing the congestion of the synovial membrane. In applying the cautery in cases of bone disease it must be done freely by means of a broad flat cautery at white heat passed rapidly two or three times over a considerable area of skin; in the case of the spine, on each side of the spinous processes; in the case of the hip and shoulder, both in front of and behind the joints. After the application of the cautery warm boracic fomentations are applied till the slough separates and then savin ointment, either pure or diluted with vaseline, is used and the sore kept open for about six weeks. I believe the best results are obtained when only the superficial portion of the cutis is destroyed and where, therefore, many nerve terminations are exposed. The objection to this is that it is very difficult to keep these sores from healing rapidly and savin ointment often causes such pain that it cannot be employed. Under such circumstances it may be necessary to open up the sores as they heal by potassa fusa, nitrate of silver, or fresh application of the cautery.

“Another method of treatment which is commonly employed in the treatment of simple chronic inflammation with the very best results is to make free incisions into the inflamed tissues, aseptically, of course, on the principle of relief of tension. In the case of chronic periostitis there is no more effectual remedy than to make free incisions through the inflamed periosteum and in the case of osteitis, to gouge the inflamed bone extensively. In other cases also, especially in tense collections of fluid, the relief of the tension often leads to a cure. A good many years ago Sir Joseph Lister attempted to apply this same principle to the treatment of chronic synovial disease—the tubercular nature of the affection not being at that time thoroughly understood—and with a certain amount of success. The treatment probably acts, as I have said, by relief of tension and consequent subsidence of inflammation. That there is a considerable amount of tension in the part is evident from the way in which the wound gapes when the incisions are made. It is possible also the treatment may be efficacious in another way, for as the wounds heal the young tissue contracts, and this pressure may exercise a beneficial effect. Where the result is partially successful it is not unusual to see a depressed scar at the seat of incision, with little or no thickening in its immediate neighbourhood, great improvement or even cure of the disease having occurred around the incisions, but not elsewhere. Lastly, there may possibly be some meaning after all in the old formula of the induction of healthy action in the part. The process of repair going on actively and well at one part may in some way that we do not understand exercise a favourable influence on the neighbouring diseased parts. That good results may follow simple incisions into joints the seat of tubercular disease is not more surprising—indeed not so surprising—as that good results follow simple laparotomy in cases of tubercular peritonitis; and yet there are now numerous cases on record in which the abdomen has been opened in cases of tubercular peritonitis either intentionally or by mistake, and where, though nothing further was done, though the wound was simply stitched up again, considerable improvement, in some cases apparently cure followed the incision. With our present improved methods of performing arthrectomy and treating chronic abscesses I think that simple arthrotomy has a comparatively small field. When we have once gone so far as to lay open a joint we may as well go somewhat further in most cases and remove at least as much of the tubercular tissue as is easily accessible. At the same time, there are some cases in which the disease is more or less stationary, or only progressing slowly, where an aseptic arthrotomy is sufficient to lead to recovery taking place. The cases most likely to do well are those where the thickening of the synovial membrane is not very great and is firm, and where on cutting through it no cheesy or softened spots can be seen. Of nineteen cases of knee-joint disease treated in this way mine got well. So far the methods considered do not act on the bacilli directly, they only aim at improving the general nutrition of the tissues or diminishing or removing the inflammation around the tubercular deposit, thus putting the tissues in a better position to resist the invasion and destroy the parasite. I must now pass on to the consideration of the

means which act more directly on the parasite and the tubercular tissue:

"Before going on to the operative measures I may say a few words about Koch's tuberculin treatment. I need not go into any detail as to this matter because I have nothing new to say, and the conclusions to which I have come are very much those which I mentioned as provisional conclusions in the paper which I read at the Medico-Chirurgical Society now more than a year ago. At that time I held that the direct risks of the treatment were much overrated, more especially the risk of acute tuberculosis and I still think that this is the case. In none of the cases in which I used tuberculin—nearly sixty in number—did acute tuberculosis occur, while curiously enough three out of nine cases, on which I was consulted or in which I considered the advisability of the treatment but decided against it, died of tubercular meningitis, and one developed an acute tubercular joint disease about fourteen days after we had determined not to employ tuberculin. In my opinion the two great dangers of this treatment are (1) its use where there are septic cavities or surfaces and (2) leaving it off too soon. As regards the first danger, the chief trouble lies partly in the increase of the inflammation as the result of the action of the tuberculin and partly in the weakening of the tissue by this inflammation allowing the pyogenic organisms to penetrate further and more rapidly. As regards the second danger, that of leaving off the treatment too early, it certainly is the fact that under such circumstances recurrence takes place quickly and in my experience the disease seems to progress more rapidly than before the treatment was employed. I do not think that I can say the same when the treatment has been continued for some months and then left off; at any rate, speaking of lupus, while under these circumstances it has recurred in places pretty quickly at first, it has afterwards seemed in several cases to come more or less to a standstill, or even to improve somewhat. Certainly in several of the cases the condition of the patient some months after the treatment was stopped has not been so bad as before it was commenced, nor so bad as it seemed likely to become when recurrence first began to take place. As to the remedial powers of tuberculin, there can be no doubt that in many cases where the conditions are favourable a certain amount of improvement follows its use, which, however, but rarely ends in a cure of the whole area within a reasonable time. In only three of the cases where no operation was performed has the improvement been complete and lasting over the whole surface. These were two children with synovial disease of the knee-joint and one patient with phthisis. In all three cases the treatment was continued for about five months and these patients remain well. Four other cases where sinuses were present which healed at the time remain healed. In all the others in which the treatment has been stopped recurrence has taken place; but in several bad cases of lupus considerable tracts which were previously diseased have remained well, showing, along with the cases just mentioned, that tuberculin really has the power of causing the permanent disappearance of tubercular tissue under certain conditions. From the microscopical appearances I conclude that the main condition is that the tubercles shall be isolated and not aggregated into masses. Isolated tubercles seem to be readily infiltrated with inflammatory cells and disappear, while only the external portions of tubercular masses are in relation to the blood stream. As it is very rarely that in the tubercular area there are only isolated tubercles or very small groups of them, it is very seldom that a complete cure can occur, at any rate within a short time. Although, however, larger masses are not destroyed by tuberculin, their growth is brought to a standstill for a time at least, and the question is for how long this condition of standstill can be kept up. This seems to vary very much in different cases; but, on the whole, when the injections are given frequently in the manner which I recommended in my paper I think that the disease may in a good many cases be kept in check for a long time. In only two of my cases are the patients still going on with the treatment—viz., in two medical men with phthisis—and these patients, though very ill and rapidly going downhill when the treatment was commenced, quickly picked up, even though staying in London during cold and very foggy weather. They have now been at work for more than a year as surgeons on board ships and have no symptoms of disease. They inject themselves every day or every other day, and, if they follow my advice, will continue to do so indefinitely. On the whole, I think that considering the indefinite length of time that the treatment

must be continued and the danger of leaving it off, it does not come into play in those cases of external tuberculosis which are accessible to other local measures. On the other hand, in phthisis I think that the treatment has been unduly discredited and too hastily abandoned, and in some cases of internal tuberculosis which come under the care of the surgeon and where no really radical measures can be adopted, as in the cases of bladder tuberculosis previously mentioned, the use of tuberculin or one of its constituents may be of some assistance in retarding the progress of the disease.

"Various substances have been used both generally and locally with the view of interfering with the growth of the bacilli, but without any special advantage. It has always seemed to me that something might be done by trying to saturate the tissues with some harmless substance which would render the soil unsuitable for the growth of the tubercle bacillus and among other things I have tried the benzoate of soda with doubtful success. Further, attempts have been made by injecting solutions of various substances into or around the tubercle to cause calcification (Kolischer with phosphate of calcium) or encapsulation (Lannelongue with chloride of zinc) of the tubercle, but without any real advantage. Various antiseptics have also been injected into the tubercular tissue with the view of destroying the bacilli—for example, carbolic acid, creasote, guaiacol, &c.; but these substances have failed in their object and only irritate and weaken the tissues and enable the bacilli to spread. For example, the infection of animals by inhalation of dried sputum is rendered more certain if at the same time inhalations of sulphurous acid are administered; and the result of the employment of inhalations of creasote in rabbits which are already tuberculous is not to prevent the disease in the lungs but actually to make it spread more extensively than in the control animals. There has been much controversy as to the anti-parasitic and anti-tuberculous action of iodoform. Certainly no true anti-parasitic action can be produced outside the body. Organisms grow, though perhaps more slowly, on substances covered with iodoform. Indeed, septic infection has occurred in wounds from powdering them with dry iodoform and therefore in an operation where the skin is previously unbroken iodoform cannot be recommended as an antiseptic; and yet if it is employed as an application to a putrid sore the smell very soon disappears and suppuration diminishes. As an explanation of this fact it has been stated that while pyogenic organisms grow in material containing iodoform their poisonous products are apparently decomposed as soon as they are produced, and this decomposition is accompanied by breaking up of the iodoform, the free iodine possibly then acting destructively on the organisms. If the bacterial products are thus broken up the bacteria will be deprived of their weapons, without which they cannot do much harm, and will be more rapidly destroyed by the tissues. Thus iodoform may really be of some use in tuberculosis. It has been recently pointed out by Krause that iodoform acts better in closed cavities, such as abscesses than on a free surface and that better results will be obtained by packing tuberculous wounds with gauze saturated with iodoform than by sprinkling it over the surface. Certainly I have had several cases lately which seem to confirm this view where tubercular sinuses have done extremely well by slitting them up and stuffing them with iodoform gauze, better than formerly by scraping and draining them or injecting iodoform and glycerine."

Reference was then made to the question of cases suitable respectively for expectant treatment and for operation, and the various points which influence the decision were discussed. [See a paper on this subject in *THE LANCET* for October, 1890.]

### LECTURE III.

The modes of complete removal of the disease in cases of tubercular joint affections are three in number—viz.: (1) complete removal of the diseased tissues along with as little as possible of the healthy structures—i.e., arthrectomy; (2) removal of the diseased tissues, along with certain portions of the ends of the bones whether diseased or not—i.e., excision; and (3) amputation above the affected joint. Arthrotomy has been already discussed, and it was pointed out that it was only suitable for very few cases, and that if a joint was opened it was best to remove at least a portion of the affected tissues. This question of partial arthrectomy will be again referred to. Many circumstances influence the choice of the operative measure, the chief of which are the age, the general condition of the patient and the local condition. As regards the treatment of chronic abscess, drainage

is almost entirely given up and more radical measures are adopted: 1. A chronic abscess being a tubercular tumour with softened centre the ideal treatment is to dissect it out as one would dissect out a cyst, and this is what I always do when the situation and size of the abscess permits. Where the abscess has started from a tubercular deposit in the bone the removal of the abscess and the affected bone leaves a clean cut wound which heals by first intention and thus the process is cut short. For example, in chronic abscess connected with a carious rib a cure is at once obtained by dissecting out the abscess and removing the affected part of the rib. 2. Where it is not possible to dissect out the wall on account of its size and connexions the next best thing is to make a large opening into it sufficient to admit the hand if possible and try to peel and dissect out the wall; of course if the abscess has started from a deposit in bone, that ought also to be removed if accessible. 3. Failing either of these plans there remains the method of making a smaller incision into the abscess, and attempting to get rid of the wall as thoroughly as possible by scraping with sharp spoons, rough sponges &c., washing out all the debris, perhaps filling the cavity with a 10 per cent. emulsion of iodoform in glycerine, and stitching up the wound. By this means healing can usually be obtained though the process may have to be repeated more than once; the bone deposit, if present, cannot however be satisfactorily cleared out.

Another important factor influencing the nature of the operation is the septic or aseptic condition of the part. Sepsis aids the spread of the tubercular disease, both locally and generally, and also complicates the operative procedures, because it introduces the risk of the various septic diseases; hence it often necessitates the employment of more severe operative procedures than would otherwise be necessary. Hence in treating a case of tubercular disease with septic sinuses it is, I think, advisable in most cases to do more than merely put the part at rest; some operative treatment should as a rule be adopted. Where it is not deemed desirable to proceed to radical measures I believe the best treatment is to lay the sinuses freely open, scrape or clip away the walls, remove as far as possible the starting point of the original abscess, sponge the surface with undiluted carbolic acid, stuff the wound with iodoform gauze or with cyanide gauze freely sprinkled with iodoform and allow it to granulate from the bottom. My experience is that much better results are obtained in this way than by simply enlarging and scraping out the sinuses and inserting a drainage-tube, as was the method formerly employed. In cases of joint disease, however, this method is only rarely applicable, and in most cases where sinuses lead into joints or are multiple and where the disease is advancing, one of the three radical measures must be adopted. At one time I was inclined to think that the presence of septic sinuses excluded arthroectomy, but I have now done several complete arthroectomies in such cases, sponging the surface of the wound afterwards with undiluted carbolic acid and with good results.

The next point considered was as to the desirability of performing partial operations. Where subsequent mobility is desired, a great objection to complete arthroectomy is that the fibrous capsule is often also removed and that the ligaments must be divided in order to get at the whole of the joint, and thus its strength and mobility are impaired. At first it seemed to me probable that complete removal of the disease was not always necessary and that a partial arthroectomy might be sufficient in a certain number of cases; the grounds for this belief were the good results of expectant treatment, of arthrotomy, actual cautery, aseptic drainage of abscesses, tubercular peritonitis &c., showing that comparatively little is required in some cases to turn the scale in favour of recovery. In excisions also, as formerly performed, no attempt was made to remove all the diseased tissues and yet healing occurred in a considerable number of cases, although it is true fistulae frequently remained open for a long time. The results of partial arthroectomy in the case of the hip-joint and knee-joint were mentioned. In the case of the hip-joint a complete arthroectomy is very difficult, but the lecturer mentioned five cases in which he had performed a partial arthroectomy; in three of them with the view of removing tubercular sequestra, which were evidently present in the neck of the bone.

The lecturer confessed that on the whole he was disappointed with the results obtained by partial arthroectomy and the conclusion he had come to was that this operation has only a very limited field, and that in most cases where it becomes necessary to remove diseased tissue complete removal

is preferable. In a few cases, however, partial arthroectomy may be of use. In some cases in the knee-joint also it may be sufficient, especially in cases where on cutting into the joint the synovial membrane is found not to be markedly pulpy, where the disease is in the substance of the membrane, not on its surface, and does not affect the bone, and where no cheesy spots are present. In other cases it is best to go on to complete removal of the affected tissues. Mr. Watson Cheyne said:

"By arthroectomy I understand all operations by which the whole of the tubercular tissue is removed along with as little as possible of the surrounding healthy tissue. We may perform a complete arthroectomy without opening the joint at all, as in the hip-joint case, where I tunneled along the neck of the femur, or without removing any tissue from the joint, as in the elbow case, where I removed the tubercular deposit from the external condyle, or with the removal of a limited portion of the synovial membrane, as in the other elbow-joint case mentioned. I term the arthroectomy 'complete' when the disease is completely removed, not necessarily when the whole of the structures of the joint are cut away. As a rule the operation is a very extensive one, and requires much patience and great care for its satisfactory performance, because the whole synovial membrane at least is involved. The diseased tissue must be removed by careful dissection; scraping is quite unsatisfactory, except perhaps as regards small points, especially in the cartilage, and if employed it must be very thoroughly done. Let me describe a complete arthroectomy of the knee-joint, where the whole synovial membrane is involved. The first thing is to expose the capsule very thoroughly, and this I do by means of two free longitudinal incisions, one on each side of the patella at a little distance from it, and I think it is best in the first instance not to open the joint. Having made out the limits of the capsule the tissues in front of the synovial membrane are carefully dissected off and the whole of the membrane behind the quadriceps is thoroughly exposed. The dissection is then carried to each side over the condyles, remembering that a fold of synovial membrane extends backwards for a considerable distance over the surfaces of the condyles; the lateral ligaments are then divided and the synovial membrane separated from them. The dissection is then continued inwards to the edge of the patella on each side and behind the ligamentum patellae. The membrane is next detached all round where it is reflected on to the cartilages of the various bones and cut away as far back on each side as possible. The joint is thus freely exposed from the front and a fringe of synovial membrane is seen around the edge of the cartilages of the femur, patella and tibia; this is carefully removed, and then one may or may not connect the two longitudinal incisions by a transverse one over the patella, sawing that bone transversely. Usually I have not required to do this, but by dislocating the patella first to one side and then to the other I have been able to get free access to the whole joint. The crucial ligaments are next divided and thoroughly cleaned, or, if much diseased, removed, and special attention is directed to the condition in the inter-condyloid notch. The joint being then forcibly bent the semilunar cartilages are removed and the dissection of the synovial membrane is resumed. It is quite easy as a rule to define the outer part of the synovial membrane on each side, and having done so separation is gradually effected by the finger or some blunt instrument between the posterior part of the capsule and the vessels and structures behind, and this is continued till the points of reflection of the capsule behind on to the femur above and the tibia below are well defined. The synovial membrane is then cut off at these points and the fringe around the cartilages carefully removed. Having now got away all the synovial membrane the ends of the bones are easily protruded through the wound and the cartilages carefully examined. If any depressions are seen they are carefully cleaned out; if they are loose or thinned anywhere that portion is removed along with a thin layer (quarter of an inch) of the bone beneath. Very often the cartilages are covered with a thin layer of soft tissue and this must be got away either by scraping the surface with the edge of the knife or by scrubbing it with a nail-brush. If the cartilage is absent at any part and the surface of the bone carious, a thin layer of the bone is cut away at that part, bearing in mind that the tubercular tissue only extends into the bone for about one-eighth of an inch; this layer can usually be removed by the knife. Of course if at any part the hole in the cartilage or the carious patch of bone is found to lead to a deposit in the bone that must be

thoroughly cleared out. Having satisfied ourselves by fresh inspection that all the disease has been removed the wounds are closed, the crucial ligaments if left being stitched, and the patella if divided being wired. A drainage-tube is seldom necessary, or if used should be removed in two or three days. I think it is best in most cases not to use a tourniquet; it is easier without it to distinguish disease; the pulsation of the popliteal artery can be felt, which is of importance in dissecting out the synovial membrane posteriorly and the oozing from the wound is less. Subsequently no passive motion should be employed, and as there is a very great tendency to flexion in children a back splint should be worn for a long time, sometimes for years."

The procedure in other joints is essentially the same. In the hip it is necessary to add a posterior incision to the ordinary anterior one for excision. In the ankle good access is obtained by a long longitudinal incision in front of each malleolus, removing the anterior part of the synovial membrane in the first instance and then either removing the astragalus or dividing the malleoli in order to get access to the rest of the joint. Mr. Cheyne prefers the removal of the astragalus and has had several cases, all with most satisfactory results, the disease being eradicated and an excellent movable joint obtained; indeed it would be difficult to say in these cases that the astragalus had been removed. In the elbow longitudinal incisions over each condyle were recommended without division of the olecranon, care being taken on the outer side to avoid the posterior interosseous nerve. The wrist-joint is rarely affected in children and complete arthroectomy as distinguished from excision of the carpus cannot be done. In the case of the tarsus it is sometimes possible, by removal of individual bones with the surrounding synovial membrane, to cut short the disease at an early stage and obtain an excellent functional result. The lecturer had had several cases where it is now impossible to tell that anything had been removed. The lecturer then said: "The conclusion which seems warranted by all the facts is that arthroectomy is the proper radical operation in children up to fifteen or sixteen years of age and excision in patients who have reached their full growth. As regards the hip-joint a really complete arthroectomy is almost impossible, but in children I think that in many cases partial operations—such as clearing out abscesses, partial arthroectomy &c.—are often preferable to excision as regards the ultimate result, though no doubt there are cases where removal of the head of the bone is desirable. For example, in primary acetabular disease, with or without abscess, inside the pelvis satisfactory access can seldom be obtained without removing the head of the bone. Again, where the head of the bone is much diseased, or the epiphysial line destroyed by the tubercular deposit it is better to cut through the neck. And also in cases with septic sinuses where operation becomes necessary slitting up the sinuses, excision of the head of the bone and subsequent stuffing of the cavity with iodoform gauze is probably the best practice. Apart from the question of shortening, which is not so very great if only the head of the femur is removed, excision leaves a weaker and less stable joint than is obtained in other ways. In the case of the knee-joint arthroectomy possesses no advantage over excision as regards the immediate result. On the contrary, as a stiff joint is what one aims at, a firmer result will be obtained by excision; but in patients who have not reached their full growth the interference with growth after excision is so serious that it should not be undertaken. Certainly in young children excision of the knee-joint is not to be thought of for a moment. In adults, however, a better ankylosis is obtained by excision and in my opinion it is the preferable operation. In the case of the ankle arthroectomy, with or without removal of the astragalus—I think in most cases with—is the preferable operation for children and gives most satisfactory results. I have not had the opportunity of trying it in adults, as the cases of ankle-joint disease which I have lately had have either not been limited to the ankle or if requiring operation have necessitated amputation, but I should be very much inclined in a suitable case in an adult to perform arthroectomy with removal of the astragalus instead of excision. The remarks which I have made as regards the knee apply also in the main to the elbow. Arthroectomy is the operation for children and very satisfactory movement is thereby obtained. Excision is, however, I think a better operation for adults; movement is more easily obtained and the disease more readily eradicated. As regards the wrist and tarsus, complete arthroectomy is of course impossible, and in children I should do what I could with partial operations. Fortunately

wrist-joint disease is not common in children, and in adults excision often gives a very good result. In the case of the tarsus in children it is sometimes possible, as I have already mentioned, to get an excellent result by removal of the affected bone and synovial membrane or of a healthy bone, such as a cuneiform, so as to get at the synovial membrane. The shoulder stands, I think, on the same footing as the hip in childhood, but it is essentially a disease of adult life, and in adults excision is the radical treatment."

## THE ELIMINATION OF WATER AND THE PATHOLOGY OF DROPSY.

By A. HAIG, M.A., M.D. OXON, F.R.C.P. LOND.,

PHYSICIAN TO THE METROPOLITAN HOSPITAL AND THE ROYAL HOSPITAL FOR CHILDREN AND WOMEN.

IN the debate on Dr. Dickinson's paper on Renal Dropsy<sup>1</sup> at the Royal Medical and Chirurgical Society on May 11th, I made a few remarks on these points, and I propose in this paper to state more definitely and distinctly what I know about the elimination of water from the body and the way in which I think it bears on the pathology of dropsy. To do this as completely as possible I shall examine the matter in its physiological, experimental, clinical, and pathological bearings, and shall point out that in physiology there are certain conditions to be met with every day in which though there is an excess of water in the blood and tissues of the body it is nevertheless unable to pass out either by the kidneys, the skin, the lungs or the glandular secretions; in other words, it is held back and retained in the body. In experimental work I shall point out that bearing in mind the physiological conditions that determine the excretion or retention of water it is possible to increase or diminish its excretion by the kidneys at pleasure. With regard to clinical work I shall point out that precisely the same thing holds in disease, and that, speaking generally, in pathology just as in physiology the urinary water is from hour to hour and day to day inversely as the uric acid excreted along with it. I shall further point out that the action of a large number of so-called diuretic drugs is due solely to their action on uric acid, and that certain disease processes which similarly affect the excretion of uric acid act in the same way as regards the elimination of water. Lastly, in pathology I shall show that the same factors which we have met with in physiology do here also account for the retention and accumulation of water in the body, and so for the most important point in the causation of dropsy, and that this knowledge of causation gives us very great power over the phenomena of disease. Before I begin I must state one point clearly, because it is the peg upon which all the rest hangs—namely, that, other things being equal, the urinary water is from day to day and from hour to hour inversely as the uric acid excreted along with it, because a part of the uric acid excretion passes through the general circulation and contracting the arterioles and capillaries prevents for a time the excretion of water. The first part of this statement is a fact which can easily be observed by anyone, and which, as I have pointed out in the *Journal of Physiology*, vol. xiii., is as well seen in the researches of others as in my own. The second part is my explanation of the fact, for the full discussion of which I must refer my readers to my book<sup>2</sup> (p. 100 and elsewhere).

In making the above statement I do not intend to pass over the action of other factors, such as perspiration and digestion, on the excretion of water, for I know very well that profuse perspiration may reduce the hourly excretion of urine to very small proportions indeed, and that during active digestion the excretion tends to be small, quite apart from the action of uric acid. Nevertheless, apart from the excessive action of these factors, the effects of uric acid on the excretion of water are generally plainly visible either from hour to hour or from day to day. To illustrate these points I will now give a few figures from my last six months' work at the excretion of uric acid and urinary water. Here we have 148 nearly consecutive days in which the hourly excretion of water in sixteen hours of the day ending 10.30 p.m. averages 54 cc., and in eight hours of the night 72 cc.

<sup>1</sup> THE LANCET, vol. i. 1892, p. 1082.

<sup>2</sup> Uric Acid as a Factor in the Causation of Disease J. & A. Churchill, 1892.

Now, it is well known that the excretion of uric acid is just the reverse of this, being most in the day and least at night; and in my book (previous reference page 16) there is a figure showing the large excretion of urates in the day hours and it further shows that when uric acid comes below urea the water at once rises. If we take single days out of the same 148 days the same thing is again seen. Thus I give five days in which the excretion of water was at its lowest and five days in which it was at its highest, giving the relation of uric acid to urea corresponding to each.

Date.	Water in cubic centimetres.	Relation of uric acid to urea.
Jan. 17th .....	840 .....	1 to 22
Jan. 29th .....	900 .....	1 to 17
Dec. 3rd .....	920 .....	1 to 24
Jan. 7th .....	930 .....	1 to 23
Feb. 6th .....	930 .....	1 to 24
Oct. 28th .....	2100 .....	1 to 30
Nov. 5th .....	2070 .....	1 to 30
Oct. 16th .....	2000 .....	1 to 32
Oct. 22nd .....	2000 .....	1 to 32
March 9th .....	1990 .....	1 to 36

*Note.*—Only the relative excretion of uric acid is here given for reasons which will be found elsewhere (*Ibid.*, p. 12).

It will thus be seen that, though speaking generally, there is less uric acid when there is more water and *vice versa*; they do not absolutely correspond, as there is less water with an excretion of 1 of uric acid to 36 of urea than with 1 to 30, and again there is more with 1 to 17 than with 1 to 22. But this is simply because other things are not equal; when there is no excess of fluid in the body relaxing the arterioles will not cause diuresis, and conversely when water has been held back for several days relaxing the arterioles will cause a correspondingly great diuresis and still more is this the case in dropsy, as we shall see presently. Still, other things being equal, the effect of uric acid is quite plain and distinct and the water is either from day to day or hour to hour inversely as the uric acid.

If we now turn to the experimental aspect of the question the same fact stands out even more clearly; for all drugs that hinder the solubility of uric acid and clear it out of the blood relax the arterioles and cause diuresis, and indeed not a few drugs whose diuretic action is well known owe this property entirely to their action on uric acid and so indirectly on the arterioles. Thus opium, mercury, iodide of potassium and other iodides, salicylate of soda, caffeine, and lithia salts, all produce more or less diuresis and diaphoresis, and all have this also in common—that they clear the blood of uric acid. Opium is often used, either alone or in combination, for its diuretic or diaphoretic properties. I have shown that it raises the acidity, diminishes the excretion of uric acid, and clears the blood of it.<sup>3</sup> A good deal has been written about the diuresis produced by mercury and I have shown that it forms an insoluble compound with uric acid, clears it out of the blood and relaxes the arterioles.<sup>4</sup> Iodides also are fairly well known as diuretics, and my researches show that at the time they cause diuresis they diminish the excretion of uric acid and clear it out of the blood, thus allowing the arterioles to relax. Further, the uric acid thus held back passes through the blood when the drug is left off, causing contracted arterioles, headache and scanty urine; in fact, a rebound, just such as is met with after opium, mercury, iron, lead, lithia, or any other members of this group. A good deal also has been written about the diuresis produced by salicylate of soda,<sup>5</sup> but its effects in this direction are entirely dependent on the fact that it clears the blood of uric acid. Unlike the drugs I have already mentioned, it clears the blood of uric acid, not by rendering it insoluble and retaining it, but by rendering it soluble and producing its elimination by the kidney, and a knowledge of this fact gives us the explanation of an important point in which the diuresis produced by a salicylate differs from that produced by the before-mentioned drugs. Take a dose of opium, mercury or an iodide, the diuresis they produce comes quickly within a few hours of swallowing the dose—i.e., they quickly clear the blood of uric acid and relax the arterioles; but with a dose of salicylate this is not so. Take fifteen grains of salicylate of soda three or four times in one day, the urine will not be at all profuse; on the contrary, it will be rather

scanty. Continue the same dose next day and towards the end of the second twenty-four hours there may be a marked diuresis.

Now, the explanation of this is simple. On the first day of its action the salicylate meets with a large amount of uric acid and passes a great deal of it through the blood and out by the kidney. The arterioles are consequently contracted and there is no diuresis. On the second day, however, the immediately available supplies of urate run short and excretion falls down almost to the level of formation. There is but little urate in the blood, the arterioles can relax and diuresis results. If a patient has a large amount of urate in store the diuresis with salicylates may not occur till the third day, but in my own case it comes almost invariably about the end of the first thirty-six hours. It is evident then that the diuresis produced by a salicylate is not due to its direct action on the arterioles, but to its indirect action on the amount of urate contained in the blood and varies in accordance with the amount of this substance that it meets with. Precisely the same thing holds with the alkalies, soda and potash, as we shall see presently. Their first action is to increase the excretion of urates and the amount of these passing through the blood. The arterioles are therefore contracted and the urinary water is scanty. Later on, when they have eliminated most of the urate, the arterioles relax and there is a diuresis, or if the alkalies are left off this occurs at once, but as alkalies are much less powerful excretants of urate than salicylates the blood is not so quickly cleared of urate and the relaxation of arterioles and diuresis do not occur for several days. Caffeine is well known to cause diuresis. I have pointed out that it diminishes the excretion of urates and relaxes the arterioles. It is also well known to be useful in conditions of migraine and depression, no doubt from its action on the urates in the blood. Salts of lithia, again, produce a marked diuresis and this diuresis comes quickly, resembling that produced by opium, mercury and the iodides and differing from that produced by salicylates. But lithia salts act as alkalies, increasing the alkalinity of the blood and diminishing the acidity of the urine and we have just seen that the alkalies (soda and potash) increase the excretion of urates and diminish the urinary water. Here again, as in the case of salicylates, we have the most absolute proof that the scanty urine or diuresis produced by drugs is due not to their action on the vessels, but solely to their influence on the solubility and excretion of urates, which have a powerful influence on the vessels. What is the action of lithia salts on the excretion of uric acid? They greatly diminish the excretion of uric acid, clearing it out of the blood and relaxing the arterioles; hence they produce diuresis.<sup>6</sup> Soda and potash increase the uric acid and diminish the water.

I now come to a very interesting point in which my researches on these matters have been beautifully confirmed by those of others and where also what was a blank in my research has been filled in in a manner which leaves little to be desired on the score of completeness. For in a valuable note in THE LANCET<sup>7</sup> I find the following taken apparently from a thesis for the degree of M.D. of the St. Petersburg Medico-Chirurgical Academy under the heading "Effect of Alkalies on Metabolic Change." "As the effect of alkaline drugs on the nature of the metabolic changes which albumen undergoes in the system has not been satisfactorily worked out, Dr. Yavein has made a series of elaborate observations on the subject, employing citrate and carbonate of soda for the purpose. The daily quantities of the drugs administered were 300 grains or more. The result showed, as a rule, that there was but little effect on the assimilation or on the metabolic change of albumen. There was, however, a considerable increase in the neutral phosphates as compared with the acid phosphates of the urine. As a rule the loss from the skin and lungs was diminished and after the alkali had been discontinued the quantity of urine increased. The body weight increased while the alkali was being taken and decreased afterwards, the increase being probably due to the diminished loss of moisture and the decrease to the augmented secretion." I have quoted this annotation in full because almost every word of it bears importantly on what I am saying.

With regard to the effects of alkalies on the excretion of urinary water, I could have told Dr. Yavein all about this

<sup>3</sup> *Ibid.*, p. 32 and elsewhere.

<sup>4</sup> *Ibid.*, p. 33.

<sup>5</sup> E ubor, in *Deutsch Archiv für Klin. Med.*, xii., p. 129

<sup>6</sup> See *Uric Acid*, p. 29, and *Med. Chir. Trans.*, vol. lxxi., p. 287. *THE LANCET*, vol. i. 1892, pp. 320 and 332.

several years ago and I could also have told him the way in which they produce these effects. I could have told him also that they diminished the excretion of water from the skin and that in the glandular secretions generally. But I did not know (and if his observations are confirmed they will constitute a most valuable addition to our knowledge in many ways) that the loss of water from the lungs is diminished at the same time with that from the kidneys, the skin and the glands. If this is the fact, it shows at once that when uric acid contracts the arterioles it contracts them all over the body and not only obstructs the exit of water from the kidneys, the skin and the glands, but also from the lungs. If this is true, we come at once in sight of a possible explanation of the undoubted clinical connexion between phthisis, chronic bronchitis and asthma, on the one hand, and gout and Bright's disease on the other. I have always inferred that uric acid, when it contracted the arterioles of the general circulation, also contracted those of the lungs; but if Dr. Yavein is right, we have here a method by which this effect on the lungs can be estimated. It may interest Dr. Yavein to know that I have pointed out that the valuable researches of Dr. Lauder Brunton prove that drugs like digitalis which contract the arterioles, diminish or even completely arrest the flow of water from the kidneys, thus paralleling exactly the action of uric acid, to which I of course attribute his results with alkalies.

With regard to the metabolism of albumens, on which Dr. Yavein apparently found that alkalies have but little effect, I have written a good deal, as indeed my whole explanation of the causation of Bright's disease hinges on the effects of urates on metabolism; and I would point out that if he is able to continue his researches in this direction he will probably find that the effect on metabolism is proportional rather to the amount of urate than an alkali meets with in the body than to the absolute dose of alkali. Thus if 300 gr. of carbonate of soda cause the excretion of 15 gr. of uric acid in one man and of 20 gr. in another the depression of metabolism will be more marked in the latter, though he only had the same dose of the drug.

As regards physiology and experiment we have now seen that in natural conditions the urinary water varies from hour to hour and from day to day inversely as the uric acid and that the excretion of water from the skin, lungs and the glands generally is influenced in the same way by the amount of uric acid in the blood. We have further seen that all drugs which clear uric acid out of the blood and diminish its excretion in the urine allow the arterioles to relax cause diuresis and a concomitant increase of the water excreted from all other glands and surfaces; while conversely all drugs which increase the urate in the blood and urine contract all the arterioles, rendering the urine scanty and diminishing the output of water from the glands and the surface of the skin and lungs. And, further, as I have shown that my law of solubilities<sup>9</sup> gives us power to increase or diminish at pleasure the amount of urate in the blood, we have it in our power to relax or contract the arterioles and thus can control to a very important extent the elimination of water from the body.

I shall now pass on to some clinical and pathological points and shall divide the conditions into (1) those in which there is an excessive excretion of urates with concomitant excess in the blood, and (2) those in which there is a diminished excretion. Under the first come migraine or the uric-acid headache in which there is, as I have shown, a *plus* excretion of urate corresponding to the attack, and with this *plus* excretion the urine is extremely scanty, as 30 to 40 cc. per hour; but when the attack passes or is driven off by the use of acids or other drugs which clear the urates out of the blood and urine, the water is profuse as 100 to 200 cc. in the same period of time—in other words, the water held back in the body during the period of uric acidemia and contracted arterioles passes out at once as soon as they are relaxed. Precisely the same thing applies to attacks of epilepsy and hysteria; I have shown that the urate excretion is large and the water scanty during the attack and it is well known to be profuse as they pass off. The ordinary history of a case of gout illustrates very well the same point; between the attacks, as is well known the urate excretion is large, and if the water is saved from day to day it will be found to be scanty; but when an acute attack comes on it will be seen that with the first rise of temperature there comes a more or less profuse diuresis. I know of no condition in which there is such

severe and prolonged uric acidemia as in Bright's disease, and in acute cases the water is extremely scanty.<sup>9</sup>

In chronic cases it is also during the day rather scanty; but at night the blood is to some extent cleared of urate by the rising acidity, and then there is a profuse diuresis of urine of such low specific gravity that the urine of the whole twenty-four hours seems to be profuse and watery; but here, just as in physiological conditions, the water is to a large extent inversely as the uric acid.<sup>10</sup> It is also well known that the contracted arterioles of Bright's disease are completely relaxed by the onset of a febrile complication and a great diuresis may be the result of this;<sup>11</sup> before the fever the urine was 15 oz. to 16 oz. in twenty-four hours, with the fever it ran up to 80 oz. in the same period, and an extensive anasarca was quickly removed.

This brings me to Group 2, the cases in which there is a diminished excretion of urate, and in pathology this is generally due to causes which interfere with its solubility in the blood, and in nature, apart from drugs, this is generally due to a diminution of the alkalinity of the blood. Now it has been shown, by Peiper and others, whom I have often quoted, that fever diminishes the alkalinity of the blood, and there is no doubt that it also increases the acidity of the urine. Therefore fever is the pathological condition in which there is least urate in the blood and urine, and it is well known that fever markedly relaxes the arterioles and the one effect is the result of the other. Now, if in any hospital patient the urine is being saved from day to day and the temperature has been for some time normal or subnormal, the onset of any fever will be seen to be accompanied by a more or less profuse diuresis, and this will continue so long as the fever continues to keep the blood free from urates on the one hand and so long on the other as there is any excess of water to be removed; hence though there is a diuresis in every case under these conditions, it is most marked in cases like the one mentioned above, where there is dropsy. To such an extent is this true that I would undertake to point out the days on which such a patient's temperature had risen, simply from the record of the water passed, provided no drugs affecting the problem had been given. To give an instance of this from recent clinical experiences I would refer to the so-called "diuretic action" of injections of fresh thyroid juice as used in cases of myxœdema. These injections cause a slight rise of temperature and relax the arterioles, and I have no doubt that the diuresis they produce, which is probably beneficial, is simply and solely due to the febrile movement, and might be brought about by the injection of any organic juice that produced a similar rise of temperature. Thus, I notice that my colleague, Dr. Davies, says in speaking of an interesting case of myxœdema which he showed at the Clinical Society, "The injections caused a gradual rise of temperature followed by diuresis."<sup>12</sup> I can show that a similar rise of temperature, however produced, would have the same effect; and as I have remarked in "Uric Acid," p. 118, the relaxed pulse which accompanies fever and the high tension and bradycardia which follow it, are directly due to the effects of fever on the alkalinity of the blood and the solubility of the urates it contains.

I could quote many more pathological conditions which the same facts will serve to explain, and indeed I meet with them every day; but from considerations of space I shall now pass on to say a few words on the bearing of these facts on the pathology of dropsy, and some points in Dr. Dickinson's paper on the subject. He speaks of the absence of dropsy in obstructive suppression, but this is not very extraordinary, for in this condition, as I have pointed out, the skin, the lungs and the glands generally are still free to excrete water; in acute Bright's disease the vessels all over the body are contracted, and water cannot get out anywhere until they are relaxed. In such cases I have been able to relax the arterioles and produce diuresis and the removal of anasarca by applying my knowledge of the solubility of urates. I cannot act so powerfully as nature did in the case above quoted; but the diuresis is certainly proportional to the relaxation of arterioles I produce by using some of the drugs I have mentioned. Again, Dr. Dickinson goes on to say in his abstract,<sup>13</sup> "Passing to chronic conditions a contradiction presents itself, for dropsy lessens with a further increase of arterial tension." It does not seem to

<sup>9</sup> As to the causation of this severe uric acidemia, see Uric Acid, p. 225.

<sup>10</sup> *Ibid.*

<sup>11</sup> See case quoted in Uric Acid, p. 225.

<sup>12</sup> THE LANCET, vol. i. 1892, p. 976.

<sup>13</sup> Med.-Chir. Proceedings, April 20th, 1892, p. 112.

<sup>8</sup> Uric Acid, p. 60.

me that this fact implies any contradiction, for in the diagram from Dr. Lauder Brunton's paper, which I showed at the time of the debate and which can be found in his work on "Pharmacology and Therapeutics" (third edition, p. 430) it appears that with the rise of pressure the excretion of urine increases, until a point is reached, the pressure continuing to rise, at which the arteriole contraction apparently overcomes the power of the heart, and then the excretion of urine sinks down to little or nothing. Now this, I take it, is what occurs in acute Bright's disease, sudden severe uric acidæmia contracts the arterioles and overpowers the heart; hence with moderately high tension the urine is scanty. In chronic disease, however, the tension is higher and yet the urine is profuse, because the heart has meanwhile acquired power to force the blood through the kidney in spite of contracted arterioles; the contracted arterioles only stop the flow when they are able to overpower the heart. Thus the prognosis in Bright's disease with low tension is most serious, because the heart is for some reason unable to acquire power to force the blood through the arterioles; hence also when the heart fails at the end of chronic Bright's disease, dropsy at once supervenes; the arterioles are contracted all the time; but the effect of this contraction depends on the power of the heart to counteract it. Even in Bright's disease the water varies in accordance with the same laws that hold in physiology, being most in the night when the uric acidæmia is least and the arterioles are most relaxed, and least in the day when the uric acidæmia is greatest and the arterioles most contracted and the pulse also, in accordance with Marey's law, is slower in the day and quicker in the night period, varying with the relaxation or contraction of the arterioles. Thus in a case of chronic Bright's disease whose excretions I recently estimated the water was on one occasion forty-four ounces in the twelve hours ending 8 P.M. and thirty-four ounces on another, and in the corresponding twelve hours ending 8 A.M. it was seventy-four and seventy-two ounces respectively. The specific gravity of the day urine was high, 1020 and above, while the mixture of day and night urine was rarely above 1010. Here the excretion of water at night was nearly double that of the day and I hope my readers will now quite understand the cause of this. I would remark in reference to such a case that if one had seen the day urine only and apart from the trace of albumen which it frequently but not invariably contained one might have reasonably doubted whether it was a case of chronic Bright's disease at all and this, I think, is an important point to bear in mind—viz., that a good specific gravity during the day is no proof of the absence of chronic Bright's disease.

In conclusion I will merely restate my position that the elimination of water is dominated by the same law both in physiology and pathology and that the forces which in physiology cause a retention of water and an increase of body weight are the same forces that, acting more powerfully in pathology, cause dropsy and a greater increase of weight, and that the action of these forces can be demonstrated by the use of drugs, as is shown by my researches and those of Dr. Yavin which confirm them.

Brook-street, W.

## CICATRICAL STRICTURE OF PYLORIC END OF STOMACH:

FOLLOWING A BLOW ON THE EPIGASTRIUM; PYLORO-  
PLASTY; CURE.

BY JAMES LIMONT, B.Sc., M.B. EDIN., M.R.C.P. LOND.,  
AND  
FREDERICK PAGE, M.D. EDIN., M.R.C.S.

### *History of the Case and Remarks by Dr. LIMONT.*

D. H.—, aged thirty-one, a stonemason, was admitted to the Royal Infirmary, Newcastle-on-Tyne, in November, 1891, complaining of indigestion of fourteen years' duration. Up to the age of seventeen the patient had no trouble with digestion. One day fourteen years ago he received a severe blow from the shaft of a heavily laden "bogie," which had broken loose on an incline. The end of the shaft struck him with great force in the region of the stomach, and pinned him against a large stone. He remained in bed four days vomiting frequently, even fluids at once bringing on an attack. After a time he returned to work, but for almost a year he

vomited nearly every evening, and suffered from pain in the region of the stomach. During the next six months he was free from all trouble. Since that time, however, he has been subject to recurring attacks of vomiting, with more or less pain. At first the attacks would last from two to three weeks, and the intervals from two to three months. During the last two years, however, the attacks have been more frequent, lasting three or four days, with intervals of not more than four days. Before admission to hospital he had become unable to work through discomfort and weakness. His weight, which a few years ago was eight stones seven pounds, was reduced to six stones nine pounds. He stated that his appetite was good, especially in the mornings, but that half an hour after eating he felt greatly distended and had a heavy dragging pain in the abdomen. At irregular intervals he vomited very large quantities of a sour character, bringing up at the same time much wind. After vomiting he was markedly relieved and soon became very hungry. If he then took a meal he suffered little inconvenience, but the subsequent meals gave more and more discomfort. The bowels were very confined. The stomach could be seen to be markedly distended and the usual signs of dilatation were made out. In the left nipple line the stomach extended from the fifth space to the level of the umbilicus and could be made out to reach two inches to the right of the umbilicus. Towards its pyloric end could be felt a small hard body about the size of the distal phalanx of the little finger; it was not tender and moved freely with respiration. The case was diagnosed as fibrous stricture of the pylorus, probably of traumatic origin. For a month the case was treated by daily washing out the stomach by means of an irrigator. No appreciable improvement followed, and operative interference was suggested to the patient. He, however, left the hospital, but returned in February weaker and more emaciated than before, and was transferred to the surgical wards.

That this is an example of traumatic stricture one can scarcely doubt, when regard is had to the form of violence, the succession of symptoms and the condition found during operation. I have been unable to find a record of a similar case. Dr. S. Fenwick refers to dilatation following blows, but says it is generally due to displacement of the stomach produced by adhesions. The stricture here must have existed for many years, its injurious effects being, however, greatly lessened by compensatory hypertrophy of the walls. Even at the time of the operation the thickness of the wall was found to be greater than normal. It is interesting to find that a stomach dilated for so many years can regain its normal powers. Apparently neither the muscular fibres nor the mucous membrane has undergone appreciable permanent deterioration.

### *Operation and Remarks by Mr. PAGE.*

On March 2nd, 1892, the patient's stomach having been washed out with a solution of boracic acid, the abdomen was opened by a median incision, extending from the ensiform cartilage to the umbilicus. On the anterior surface of the stomach, close to the pylorus, a puckering of the peritoneum was seen, about the size of a shilling. Beneath this puckering, and occupying an area of about twice its size, a hard mass could be felt in the substance of the stomach wall. Sponges were packed about the pylorus, so as to prevent blood and mucus escaping into the peritoneal cavity. The hard mass was then cut through with scissors and the incision carried into the stomach in one direction and into the duodenum in the other, beyond the limits of the induration. The mucous and peritoneal edges of the wound were then sewn together over the muscular coat with a continuous suture of fine silk. The left angle of the wound (ending in the stomach) was next secured to the right angle (ending in the duodenum) with a Lembert's suture of silk. This converted an incision which had been made almost at right angles to the long axis of the body into one nearly parallel to it. The wound was closed with a double row of Lembert's sutures and covered with a graft of omentum. The sponges were removed and the abdominal incision sutured with silkworm gut. The patient suffered very little inconvenience from the operation. He vomited a few hours after and has never been sick since. For eight days he was fed entirely by the rectum. On the ninth day fluids were taken by the mouth, and on the sixteenth he took fish and gradually returned to his ordinary diet. On March 31st (twenty-nine days after the operation) he weighed 7st. 8½lb., having gained 1st. 3½lb. He is now (June 12th) quite well, weighs 10st., and has resumed his ordinary occupation.

Of the surgical procedures at our disposal for the treatment

of stricture of the pylorus of a non-malignant character pyloro-plasty—the ingenious operation suggested by Mikulicz and Heinke almost contemporaneously—seems to be by far the most satisfactory in its results. It has been practised pretty extensively on the Continent and in America, and attention was drawn to the operation by Keen of Chicago<sup>1</sup> last February. I am not aware, however, that any case has been hitherto recorded as having occurred in England.

Newcastle-on-Tyne.

## SOME POINTS IN THE ETIOLOGY AND PATHOLOGY OF DIABETES MELLITUS.

By R. T. WILLIAMSON, M.D. LOND., M.R.C.P.,  
MEDICAL REGISTRAR, MANCHESTER ROYAL INFIRMARY.

DURING the last four years seventy cases of diabetes mellitus have come under my observation at the Manchester Infirmary and elsewhere, some of which have presented points of interest respecting the etiology and pathology that seem worthy of being recorded.

### DIABETES AND THE NERVOUS SYSTEM.

**CASE 1.** *Marked ataxia of sudden onset; paralysis of right internal rectus; tremor of right arm; onset of diabetes seven weeks after commencement of symptoms.*—J. W., aged forty-eight, was admitted under the care of Dr. Steell to the Manchester Infirmary on May 7th, 1890. Patient was quite well until April 26th, 1890. On the morning of that day, when going to his work, he suddenly became ataxic and fell to the ground. No loss of consciousness, no paralysis of limbs. He has been unable to walk or stand since, owing to ataxia. History of alcoholism; no syphilitic history. On admission, patient is unable to stand alone; when well supported he is able to advance a few steps and throws forwards his right leg in a jerky, irregular manner. Marked ataxia; no paralysis of limbs; no rigidity; knee-jerks present; no ankle-clonus. Right palpebral fissure smaller than left; apparent ptosis of right eye; paralysis of right internal rectus; left pupil larger than the right. Slight nystagmus; slight tremor of the right arm when the limb is supported, but this is more marked on voluntary movement. Optic discs normal. Old perforation of right tympanic membrane. Temperature normal. Urine 1015, acid, no albumen, no sugar, quantity normal.—June 12th: Amount of urine increased to 92 oz.—15th: Urine pale, clear, 1024, acid, contains a large amount of sugar.—23rd: Great thirst, voracious appetite. During the first three weeks of the diabetic symptoms the amount of urine varied from 160 to 190 oz. and the sugar from 3200 to 4200 grains daily. The amounts of urine and sugar were both diminished by restricted diet. A few months later several large carbuncles developed on the gluteal region, but in course of time these and the paralysis of the right internal rectus, the ptosis and nystagmus disappeared. The diabetic symptoms, the tremor of the right hand and the ataxia persisted.

**CASE 2.** *Tumour of the pituitary body.*—A. H., aged twenty-three, was admitted under the care of Dr. Ross to the Manchester Infirmary on Nov. 16th, 1890.<sup>2</sup> History of headache and gradual enlargement of hands and feet; symptoms of acromegaly. Temporal hemianopsia of the right field of vision; in the left field vision entirely lost, with the exception of a very small area near, but a little to the temporal side of, the centre of the field. Urine 1035; no albumen, no sugar; loaded with urates. After remaining in the hospital for several weeks the specific gravity of the urine rose to 1045, and it was found to contain sugar by Fehling's test, by the phenyl hydrazin test and also by fermentation. The amount of sugar at first was fourteen grains to the ounce; the amount of urine normal. The sugar gradually increased in amount. The patient left the hospital for several months and then returned on account of an abscess which had developed in the left breast. She was admitted on the surgical side under the care of Mr. Southam. The patient complained of thirst and on examination of the urine a large amount of sugar was found. The abscess was opened and treated antiseptically and the patient put on diabetic diet. The thirst, however, increased and five days later the patient died of diabetic coma. The temperature remained practically normal. At the post-mortem examination a round-celled

sarcoma of the pituitary body was found, which pressed on the optic chiasma, and in which the left optic nerve was embedded. The rest of the brain was normal. The thyroid was a little enlarged and contained a colloid cyst. There were changes in the pancreas, which will be afterwards described. Liver enlarged; weight 5 lb. 2 oz.; signs of fatty degeneration.

The following is a good example of *diabetes following an injury to the head*:—

**CASE 3.**—M. A. R., aged eighteen, was admitted under the care of Dr. Steell to the Manchester Infirmary. The patient was a strong, healthy, stout girl up to the time of an accident seven months before admission. On going downstairs she suddenly slipped and fell down thirteen steps, the top of her head coming violently in contact with a door at the bottom of the steps. She was stunned by the fall, but did not lose consciousness. A dish which she had in her hand at the time was broken in the fall and her face was cut by the broken porcelain just below the right eye. She received a deep cut on the flexor surface of the right forearm just below the elbow. She had great pain in the head for many hours after the fall and has frequently suffered from severe headache since. Two weeks after the accident she first noticed thirst, which was soon followed by wasting. On admission, the patient was emaciated; knee-jerks absent; urine acid, 1045, no albumen; large amount of sugar present (twenty-three grains to the ounce); marked brownish-red colouration with  $\text{Fe}_2\text{Cl}_6$ . During the time the patient was in the hospital the amount of urine at first varied from 80 to 90 ounces daily; later from 56 to 68 ounces daily, with increase of sugar to 33 grains per ounce.

The next case is one of diabetes following great mental anxiety, in which purulent *cerebro-spinal meningitis and multiple abscesses in the liver* were found post mortem. It is difficult to say what was the relation of the cerebro-spinal meningitis and liver abscesses to the diabetes. Even supposing these changes were due to some complication, they are so rare as to be not unworthy of brief record. A similar case is published by Frerichs.

**CASE 4.**—J. R.—came under my care on Sept. 28th, 1890. History of an attack of vertigo and vomiting in February, 1890. Five weeks later he began to be troubled with thirst and polyuria. He had been unemployed for eleven months; had lost a large sum of money and been subject to great mental anxiety before onset of diabetes. He had obtained employment, however, at a bleaching works about one month before he first noticed diabetic symptoms. A brother died of diabetes. When first seen the patient was considerably wasted. He suffered from thirst and polyuria. Urine 1032, acid; large amount of sugar present (1 cc. of urine contained 0.0517 gramme of sugar); no albumen. Knee-jerks absent. Commencing cataract in each eye. Bowels regular. Heart, lungs, liver and spleen normal. Four months later he was admitted as an in-patient at the Manchester Infirmary under the care of Dr. Ross. During the time he was in the hospital (six weeks) the amount of sugar varied from 2500 to 4800 grains daily and the amount of urine from 90 to 130 oz. From his admission (Jan. 21st, 1891) until Feb. 24th the temperature was normal. At the latter date the evening temperature was 102° F.—Feb. 25th: Patient complained of pain in the epigastrium. Urine contained for the first time a trace of albumen, and also gave for the first time a dark reddish-brown colouration with  $\text{Fe}_2\text{Cl}_6$ . Bowels constipated. For the next three days the evening temperature was between 102° and 102.8°; then for four days the evening temperature was between 99° and 100°.—March 4th: Evening temperature 102°; pulse 96; respiration 25.—5th: Morning temperature 99.6°; evening 103.2°.—6th: Morning temperature 101.2°; evening 100.2°. Patient complained of pain in the right hypochondriac region. Edge of liver felt about one inch and a half below the ribs. No jaundice; no rigors. Patient became very restless and semi-conscious. Knee-jerks absent; calf muscles tender; no paralysis; no anæsthesia. He could be roused to answer questions until just shortly before his death at 2 A.M. on March 7th. Shortly before death the pulse was 224; respiration 72. No discharge from ears or symptoms of suppurative otitis media during the patient's illness.

*Necropsy* (abstract).—Peritoneum, pericardium, heart and aorta normal. Lungs, adhesions at right apex; small patch of broncho-pneumonia on left lower lobe and another at right apex. Left apex puckered; several small calcareous nodules and cicatrices. Kidneys normal; suprarenal capsules, medulla of each congested; two small yellowish nodules in medulla

<sup>1</sup> Medical Press and Circular.

<sup>2</sup> This patient's symptoms were the subject of a clinical lecture published by Dr. Ross in the International Clinics.

of right capsule. Spleen slightly enlarged and pulpy, weight eleven ounces. Pancreas (weight two ounces and a half) somewhat small and firm. Liver (weight five pounds), capsule normal; on section scattered irregularly throughout the right lobe, but most numerous in the outer half of the right lobe, are a number of small abscesses varying in size from a pea to a marble. Near the right border these are clustered together so as to form a large suppurating patch four inches transversely by two inches and a half vertically. The pus can be washed away, leaving small cavities. At only a few places is there any zone of hyperemia around the abscesses. Gall-bladder contains a small amount of orange-coloured bile; mucous membrane slightly congested, but no ulceration can be detected. No obstruction of cystic, hepatic or common bile-ducts. Large bile-ducts can be traced in liver substance for a considerable distance, but nothing abnormal detected. No thrombus in portal vein or any of its larger branches. Stomach: no ulceration or other abnormality of importance. Rectum, prostate and bladder normal. Spinal cord; dura mater normal. On opening dura mater, meninges of posterior surface of cord, in dorsal region, very turbid and yellowish in colour; in cervical and lumbar region, turbidity not quite so well marked. Vessel of posterior aspect of cord much distended; only slightly distended in anterior aspect. Turbidity of meninges on anterior surface. On section of the cord nothing abnormal detected. Cord hardened in Müller's fluid. Sections in all parts normal to the naked eye (excepting meninges); microscopical examination confirmed the diagnosis of purulent lepto-meningitis. Skull cap, cerebral dura mater and blood sinuses normal; base of skull, including regions of petrous portions of temporal bones, normal. Meninges of each cerebral hemisphere turbid and yellowish; distinct suppuration at the sulci. At the anterior part of the first left frontal convolution is a hæmorrhage about the size of a halfpenny, irregular in shape, situated between the arachnoid and the cortex; and passing down between the convolutions, but not entering the brain substance. The meninges of the upper surface of the cerebellum present the same appearance of purulent meningitis as those of the cerebral cortex. The membranes of the base of the brain appear normal. A small amount of turbid fluid is present in the lateral ventricles and a small amount of pus in the posterior horn of the left lateral ventricle. In the fourth ventricle nothing abnormal detected. Apart from the changes just mentioned the rest of the brain—basal ganglia, cerebral hemispheres, cerebellum, pons and medulla—appear normal. Microscopical examination confirmed the naked-eye appearances of purulent lepto-meningitis. Sections of the pons and medulla showed slight dilatation of the vessels at the floor of the fourth ventricle, but no other microscopical changes.

In the history of some of the seventy cases of diabetes there were several other points of interest. Thus great mental anxiety and worry due to loss of money, loss of employment &c., were antecedents in nine cases. In one case the symptoms came on whilst the patient was preparing for the Final B.A. Examination Lond. For a long period he had devoted almost the whole of his time, with the exception of that required for sleep and meals, to the closest study. In one case the patient had been subject to epileptic fits for several years.

As regards heredity, in one instance three sisters all suffered from diabetes. In six other cases there was a family history of diabetes. In eight cases there was a long history of very great alcoholic excess up to the time of onset of diabetic symptoms. In two cases the symptoms came on during an attack of pleurisy. In another case diabetes came on during prolonged lactation; marked wasting soon occurred and the patient died about twelve months after the onset of symptoms. I have notes of another case, in which diabetes followed a mammary abscess soon after confinement. In one case symptoms of diabetes came on during influenza, in another case during a severe cold.

#### DIABETES AND LESIONS OF THE PANCREAS.

Changes in the pancreas are of great interest, since Minkowski and v. Mering showed by their famous experiments in 1889 that diabetes could be produced in dogs by total extirpation of the pancreas.<sup>3</sup> I have examined the pancreas in four cases of diabetes.

CASE 1. *Marked cirrhosis of the pancreas.*—T. L.—, aged forty-five (under the care of Dr. Ross at the Manchester

Royal Infirmary). Diabetes mellitus, with wasting. Peculiar pinkish tinge of the urine. History of great alcoholic excess. Death by coma. Necropsy: Pancreas weighed four ounces and a quarter; was very hard and was cut with difficulty. Section showed to the naked eye that the organ was infiltrated with dense fibrous tissue, in which small masses of the remaining gland tissue were embedded. There were several small cystic dilatations of the pancreatic duct, containing small calculi and mucous fluid. Microscopical examination showed a very great excess of fibrous tissue. In some places almost the whole of the field of the microscope was occupied with dense fibrous tissue. At some parts small clusters of pancreatic cells, at other parts small lobules of degenerated pancreatic tissue, were seen embedded in the fibrous tissue. With the exception of a cavity and other tubercular changes in the right lung examination of the liver, brain and other organs revealed nothing of importance.

CASE 2. *Atrophy and fatty degeneration of the pancreas.*—T. S.— (under the care of Dr. Mackenzie, Victoria Hospital, Burnley). Diabetes with wasting. Death by coma. Necropsy: Pancreas markedly atrophied, exceedingly soft and flabby, weight one ounce and a quarter; on section studded with pale spots. Microscopical examination of sections stained with osmic acid showed marked fatty changes, especially at the pale spots. At many parts the pancreatic cells contained small fat globules. Mingled with these degenerated cells were fat cells, some small, others very large. In some parts the fatty changes occupied the centre, at other parts the periphery of a lobule.

The pancreas in the case of A. H.— (tumour of the pituitary body), above described, was very large and heavy. It weighed six ounces. Microscopical examination showed a marked excess of interlobular fibrous tissue, which in some parts was richly supplied with nuclei. In this interlobular connective tissue many large clusters of fat cells were embedded, also in the interior of many of the lobules, groups of large fat cells were scattered. Whether the diabetes in this case was produced directly by the tumour of the pituitary body or indirectly through secondary pancreatic changes it is impossible to say.

In the case of J. R.—, above described, the pancreas appeared normal microscopically.

[To Drs. Steel, Leech, Ross, Dreschfeld and Mackenzie, and to Mr. Southam I am indebted for kindly giving me the opportunity of observing some of the above cases.]

## Clinical Notes:

### MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

#### ON THE TREATMENT OF CLOTTED BLOOD IN THE BLADDER BY AN EVACUATOR.

BY H. A. LEDIARD, F.R.C.S. ENG.,  
SURGEON TO THE CUMBERLAND INFIRMARY.

On somewhat rare occasions the surgeon has to deal with troublesome hæmorrhage into the bladder, where the blood in place of mixing with the urine and passing out naturally becomes clotted, and where further bleeding goes on so as to cause a painful distension of the bladder. In such a case a catheter is passed without affording relief, for the eye of it is instantly plugged. Bleeding continues owing to the presence of clot much in the same way as post-partum hæmorrhage lasts, so long as a clot prevents contraction of the uterus. Among the causes of intra-vesical hæmorrhage villous tumour occupies the first place, for the bleeding is sometimes rapid and the clotting firm; other malignant growths bleed, but, perhaps, less severely. Hæmorrhage is associated with enlarged prostate and ruptures of the bladder, but in the latter most of the blood will be intra-peritoneal. Hæmorrhage after lithotomy is usually external, but according to Erichsen venous hæmorrhage after lithotomy is apt to find its way back to the bladder and may coagulate and distend that organ. Whatever the cause may be, the object held in view is to empty the bladder, and this is by no means easy, for clots will not pass through an ordinary catheter, even when a stream of water is now and then injected down the catheter to keep the eye clear; neither will clots pass

<sup>3</sup> For discussion of the relation of lesions of the pancreas to diabetes, and for complete notes of the cases of T. L.— and T. S.—, see paper in *Medical Chronicle*, March, 1892.

through a large catheter attached to an evacuating bag. So excellent a lithotripsy evacuator as Morgan's has proved quite useless in my hands when the bladder has become distended with clotted blood. Some stronger suction power is needed than the recoil of an indiarubber bag, and all that is wanted is a brass ear syringe, some rubber tubing, and a large evacuating catheter of Bigelow's kind. In this way the bladder is rapidly cleared out; but in order to facilitate the operation I have adopted the ordinary stomach pump syringe, for with it the bladder can be emptied without disconnecting the rubber tubing at the end of each suction, in order to empty the syringe. With the double nozzle of the stomach syringe the apparatus will allow of the bladder being cleared and washed out at the same time without disconnecting the rubber tubing. As it may be convenient to have these instruments ready at hand for emergencies I have had a stomach pump syringe, some rubber tubing and a large-eyed, large-sized evacuating catheter put together in a case by Down Brothers, St. Thomas's-street, Borough, S.E. Cumberland.

“NOTES FROM A PRACTITIONER'S CASE-BOOK.”

BY HUGHES REID DAVIES, M.R.C.S., L.R.C.P.LOND.

UNDER the above heading, in THE LANCET of July 2nd, Dr. Howard Murphy notes an interesting case of dislocated patella, and in concluding his record observes: “I have not been able to find any mention of such a dislocation of the patella (if it deserves such a title) in any of the text-books.” A precisely similar case occurred in my own practice in June, 1891, and whilst I administered ether to the patient—a lady of about seventy years of age—Mr. Jonathan Hutchinson, jun., reduced the dislocation, the reduction producing a “loud snap,” as in Dr. Murphy's case. Dr. Murphy's experience and mine are peculiarly similar. My patient, like his, had mounted a chair for the purpose of adjusting a window blind, the shifting of which caused the leg to twist in some unexplained manner and the rare dislocation to occur. The after history was equally favourable. I remember there was considerable doubt at the time as to how the lower border of the patella became so firmly fixed, but I do not recollect that any very satisfactory conclusion was arrived at.

*The salicylate treatment of chorea.*—I have had complete success in the salicylate treatment of the chorea of children, especially when accompanied by a mitral murmur; but of chorea in adults I have had no experience.

My round of general practice has been singularly rich in interesting “cases” during the last two or three years, a few of which I might briefly note perhaps without being deemed tedious.

*Infantile intussusception.*—Two of these cases I have been able to successfully reduce—under an anæsthetic—by proflation per rectum with an ordinary Higginson's syringe. To the first I was called in consultation by Dr. J. C. H. Dickinson, whilst the other occurred in my own practice, and both cases came under my notice within the space of a year.

*Floating kidneys.*—Of these I have had many, sometimes single and once double. One case became an in-patient at the London Hospital, under the care of Mr. Treves, with a view to fixation of the kidney. The interest in this case was further advanced by the fact that whilst under operation a fair sized renal calculus was discovered and removed. But of this case I am hardly justified in speaking, as doubtless Mr. Treves has it on record.

*Foreign bodies removed.*—1. A needle-case from a vaginal vagina. 2. A large plug of coarse tobacco, encased in wax, from each ear of a commercial traveller—a Devonshire man. He was much troubled by tinnitus aurium and almost complete deafness, both of which symptoms were immediately relieved by removal of the foreign bodies. This patient informed me that he distinctly remembered some thirty years back being treated for earache by the west country method of plugging the ear with tobacco. Therefore, upon his own showing, the length of time during which the foreign bodies had remained in his meatus was thirty years. 3. Two saloon-pistol bullets, one from the thecal eminence, the other from the flexor surface of the first phalanx of the third finger. 4. A needle, after a year's residence, from the hand of an old lady of eighty-five. 5. The complete metallic portion of an etching-pen, at least two inches in length, which was situate for three weeks in a vertical position about

one-sixteenth of an inch from the deep palmar arch. 6. Complete occlusion of right nasal passage by a foreign body for thirteen years,<sup>1</sup> &c.

In conclusion I may say that one can hardly call “general practice” *monotonous* with such a list.

Bow-road, E.

FRACTURE OF THE UPPER JAW WITH MALAR DEPRESSION.

BY GEORGE WHERRY, M.C. CANTAB., F.R.C.S. ENG., &c.,  
UNIVERSITY LECTURER IN SURGERY, CAMBRIDGE.

FRACTURE of the upper jaw with malar depression occurs so frequently at football, and is so easily overlooked, that I call attention again to the subject, and mention a case as an illustration. A fortnight ago an athletic undergraduate called upon me and stated that he could do no reading on account of headaches, which he considered to be the sequel of a football accident five weeks before. He stated that during a match he was knocked senseless by the charge of a player, whose head struck him full upon the prominence of the cheek. Vomiting followed after a short period of unconsciousness and then apparent recovery. On examination there was a yellow stain about the left lower ocular conjunctiva where it had been blood-shot; no other sign of ecchymosis was present. The left malar prominence was slightly depressed as compared with the other side, and an irregular chink could be felt along the orbital margin. There was a very evident line of fracture to be felt on placing the finger inside the cheek on the malar process of the superior maxilla. The patient had not been able to bite on that side since the accident, and there was a remarkable gap which prevented the first molar from touching the lower teeth on that side, a condition which was probably a mere coincidence. There was a patch of numbness in the cheek, but not that definite area of anæsthesia which is found after injury to the infra-orbital nerve. Neuralgia had lately kept him awake at night.

In cases which I have briefly recorded among others to illustrate the effects of blows upon the malar bone,<sup>2</sup> though there was fracture of the jaw with malar depression, yet not more shock and not more ecchymosis could be discovered than is usual in an ordinary black eye, but a slight deformity was permanent. Other cases were followed by serious results, as orbital abscess, paralysis of the infra-orbital nerve, or serious head symptoms suggestive of fractured base. An interesting case is recorded by Mr. Holmes of a gentleman who, after a fall, received a fatal brain injury. An orbital ecchymosis during life exactly resembled that which attends fracture of the base of the skull was found after death to be due to a fracture of the malar bone near its junction with the frontal. In every case which comes under observation after a blow upon the malar prominence an examination should be made of the orbital ridge, of the malar process of the upper jaw and the zygomatic arch on the injured side. The finger in the mouth passed up beneath the cheek will readily detect any fracture of the malar process. The injury above described should be considered of interest and importance like a head injury, and, however trifling it may appear, should not be looked upon lightly.

Cambridge.

EMPHYSEMATOUS VAGINITIS.

BY H. E. WRIGHT, L.R.C.P. EDIN., M.R.C.S., J.P., &c.

DR. HERMAN, in THE LANCET of June 6th, 1891, describes a case of what he calls emphysematous vaginitis, and he remarks upon the rarity of this disease in England within the past few weeks. I have had a case in my practice here which seems to be closely allied to Dr. Herman's, especially to those cases which he quotes from German literature. Although I did not verify the presence of gas in the vesicles, it is quite possible it may have existed in some of them, as I did not pay particular attention to the point. The following are notes of the case:—

Mrs. —, aged twenty-seven, had been under my care for endocervicitis and erosion of the os uteri for nearly three months. On Sept. 2nd she came to me to have the last applica-

<sup>1</sup> THE LANCET, Nov. 15th, 1890.

<sup>2</sup> Practitioner, Sept. 1891; Camb. Med. Soc. Proc., 1889.

tion of nitrate of silver made to the cervix, and on passing Ferguson's speculum I noticed the vagina was studded with white spots, some of the size of a hempseed, others that of a small pea. The spots were milky white and about a third of an inch apart. A close examination showed them to be vesicles, and in adjusting the speculum some of the vesicles were ruptured and a watery, opaque fluid exuded. The ruptured vesicles left small pits in the mucous membrane. The cervix was quite free from the vesicles, which were most abundant in the upper two-thirds of the vagina, the lower third and the vulva being unaffected. I had never seen such a condition of the vagina before and I have a large practice in diseases of women. The milk-white spots suggested the *oidium albicans*, but closer examination clearly showed the spots to be true vesicles. The patient and her husband were surprised when I informed them of the condition of the vagina, which apparently had given rise to no special symptoms. I applied the nitrate of silver as usual to the cervix and left the vagina alone. Three days after this the husband came to me and said that his wife complained of an irritating watery discharge from the vagina and some burning of the passage and itching of the vulva. I prescribed, without again seeing the patient, some borax and glycerine, to be used in warm water as an injection two or three times a day. I heard nothing more of my patient for about ten days, when her husband came to consult me about himself. He said, "I have got the same complaint which my wife has just had. It came on a few days after I had connexion with her, which was the day before she came to you." I had advised him not to have intercourse with his wife until the vagina should have regained its healthy condition. On examining the husband, I found the whole surface of the glans penis excoriated in small spots or patches; there were no vesicles, but the condition of the glans was very suggestive. I must mention that the irritation and soreness of the penis had existed for one week prior to this visit. There was slight redness of the orifice of the urethra and occasionally some slight burning in passing urine. There was no discharge, either water or pus. I prescribed a lead lotion and in a few days he was quite well. I regret that I did not examine some of the vesicles for the *oidium albicans*, as their milky whiteness and rapid disappearance after using a lotion of borax and glycerine convince me that I might have been successful in my search.

#### ST. THOMAS'S HOSPITAL.

CASES ILLUSTRATING THE TREATMENT OF RECURRENT PELVIC PERITONITIS BY ABDOMINAL SECTION; REMARKS.

(Under the care of Dr. CULLINGWORTH.)

WE continue and conclude this week the series of instructive cases of recurrent pelvic peritonitis commenced at page 20 of our last issue. We have already published four of the cases and as this week we give the remarks of the operator, advise our readers to refer to those cases before reading the remarks. As Dr. Cullingworth points out, it is impossible to prevent the occasional formation of a fecal fistula after the separation of adhesions which are so firm as those found in the patients under his care and others of a similar character.

CASE 5.—J. L., aged thirty-one, a primipara, by occupation a nurse, was admitted into Adelaide ward on March 3rd, 1892, suffering from pain in the abdomen and sickness. Previous history: In November, 1890, the patient strained herself in her efforts to put out a fire and for a week afterwards she complained of dragging pains in the lower part of the abdomen. At the end of this time, whilst out walking, she was suddenly seized with acute pain in the abdomen, went home in a cab, being unable to walk on account of the pain, and at once went to bed. Two days

later, the period being then a fortnight overdue, she began to lose dark-coloured blood from the vagina copiously and suffered from vomiting, constipation and retention of urine. On Dec. 18th, 1890, she was admitted into the ward complaining of hæmorrhage and pain and with a distinct abdominal swelling. A diagnosis of intra-peritoneal hæmatocele and right hæmato-salpinx was made and an operation advised but declined. She left the hospital on Jan. 14th, 1891, still losing blood. The loss continued till April, when it ceased. A month later she menstruated normally and has remained regular since. In October she noticed a yellow vaginal discharge, and experienced pain in the back and left iliac region, which continued to trouble her for some months; her general health, however, did not suffer, and she remained at her duties as an infirmary nurse till February of the present year. In the first week of February last (her period being due) she experienced a sudden sharp attack of abdominal pain and tenderness, accompanied by vomiting. Her period came on the same day, the flow being much more profuse than usual. She remained in bed for eight days and then got up and resumed her duties; her period had ceased, but the pain in the abdomen continued and was aggravated by any unusual exertion. Three weeks after the commencement of the above attack there was a sudden exacerbation of pain, with vomiting and hæmorrhage. She remained in bed for a week and says her temperature reached 104° F. on one occasion. At the end of the week she was readmitted. On examination the abdomen was rigid and there was considerable tenderness over the lower part and especially in the left iliac region. Per vaginam, the right fornix was normal in height; the left was depressed by a firm, irregular, tender mass, the size of a duck's egg, occupying the left posterior quarter of the pelvis and displacing the uterus slightly forwards and to the right. The uterus was movable and slightly enlarged, its canal measuring three inches. Similar but smaller masses were felt behind and on the right. No evidence of any separation could be detected between them. The urine was normal and the temperature 101.4°. Three weeks later—viz., on March 24th—the patient had not improved and the physical signs remained unaltered. The abdomen was opened and the pelvic viscera were found obscured from view by adherent omentum and intestine. After these had been separated the left Fallopian tube and ovary were found to be enlarged, inflamed and densely adherent. During the process of separation, which was tedious and difficult, the diseased ovary was ruptured and its purulent contents (about two fluid ounces) escaped. There was a small non-suppurating cyst of the right ovary. The right tube was adherent, but not diseased. After removal the collapsed ovary measured two inches by an inch and three-quarters and its wall was acutely inflamed. The abdomen was thoroughly douched and drained for forty-eight hours. Convalescence was complete and unmarred by complications. The patient was discharged on April 18th, feeling quite well, the abdominal wound having been completely healed for over a fortnight. She reported herself a month later, and was then in good health.

CASE 6.—A. C., aged thirty-nine, married, was admitted into Adelaide ward on March 29th, 1892, complaining of abdominal pain and uterine hæmorrhage of three weeks' duration. Previous history: She began to menstruate at the age of eleven and has always been regular, the flow being somewhat profuse and lasting from five to six days. She married in 1881, when twenty-seven years of age, and has had one child, born the following year. She married a second time at Easter, 1887, having been a widow a little over twelve months, and has not been pregnant since. She enjoyed good health till Easter, 1891, when she was confined to bed for a fortnight with pain in the lower part of the abdomen. She quickly recovered from this attack and remained well till three weeks ago, when she again suffered from pain in the lower part of the abdomen and left iliac region. The last menstrual period had ceased fourteen days previously. On the following day she had a flooding with aggravation of the pain and the bleeding continued, gradually diminishing till March 24th, when it ceased. The pain, however, continued to be severe and compelled her to keep her bed. During the last three weeks she has also complained of loss of appetite, diarrhoea and vomiting. On admission she was a well-nourished woman, complaining of constant pain in the lower part of the abdomen and of flooding, which had recently stopped. The abdomen presented nothing abnormal on examination, except some slight tenderness and resistance in the left iliac region. Per vaginam both lateral fornices were found depressed, the right more than the left. Uterus

normal in position, but slightly enlarged. The sound passed two inches and three-quarters. In the right posterior quarter of the pelvis a firm irregular mass could be felt about the size of a hen's egg. On the left side there was considerable resistance, but no definite tumour. The thoracic organs were normal. Temperature 98.6°. The urine contained a decided trace of albumen.

On April 7th the abdomen was opened. The omentum was firmly adherent to the anterior abdominal wall and to the back of the uterus; there were also adhesions between the uterus and intestine which were troublesome on account of their density and vascularity. After these had been separated the right Fallopian tube was discovered dilated and flaccid, and when traced backwards and downwards it was found to be continuous with the enlarged ovary, which was lying deeply in Douglas's pouch, embedded in adhesions. With great difficulty these parts were freed, brought to the surface and removed; about three fluid ounces of blood-stained non-offensive pus escaped from the ovary during the manipulations. The adhesions were very vascular and bled freely when broken down. The left appendages were adherent but otherwise normal and were not interfered with. The peritoneal cavity was doused with hot boracic lotion and the bleeding checked. A glass drainage-tube was introduced and the wound sutured with silkworm-gut sutures. The portion of the tube removed was irregularly enlarged and contorted, four inches and a half in length, the fimbriated portion was completely occluded by its adhesion to the diseased ovary, but there was no communication between the two. The mucous membrane of the tube was swollen and acutely inflamed and covered with thick, yellow, inoffensive pus. The ovary measured two inches and a half by two inches and contained several distinct loculi lined by an inflamed membrane and full of pus. Convalescence was somewhat impeded by a fæcal fistula which made its appearance on the morning of the fourth day after a severe attack of vomiting the previous night. Fæcal matter and occasionally flatus continued to escape from the wound in gradually diminishing quantity for a month, when the escape ceased and the wound healed. She was discharged on May 26th feeling quite well. On June 3rd the patient presented herself on account of the sinus having reopened. There was a free discharge of inoffensive pus, the patient's health otherwise was excellent.

*Remarks by Dr. CULLINGWORTH.*—Recurrent pelvic peritonitis in the female is, in the immense majority of cases, an indication of the presence of pus either in the Fallopian tube or in the ovary, or in both. It therefore almost invariably calls for surgical treatment, for the anatomical position of the tube is such that pus once poured out cannot drain away as it can from most of, if not all, the other mucous surfaces of the body, whilst in the case of the ovary the imprisonment of the pus is, if possible, even more absolute. The six cases forming the above series happened all to be in the ward at the same time. They were all admitted for acute pelvic inflammation and at least four of the patients were extremely ill. The history showed that in all but one of the cases there had been previous attacks, proving the presence of some chronic source of irritation. No one who saw the cases or who reads the foregoing abstracts, carefully prepared by my house physician, Mr. Banks, can doubt that operative interference was the best method of dealing with the cases and in some of them was probably the only possible means of saving life.

How do the contents of an ovarian cyst become infected? What determines their suppuration? There seems good reason for believing that the most common channel of infection is the Fallopian tube. Given cystic disease of the ovary and suppurative inflammation of the Fallopian tube (whether septic or gonorrhœal), there is strong evidence in favour of the view that the process of suppuration may be set up in the contents of the ovarian cyst by the passage of infective micro-organisms from the diseased tube. Case 1 is a good example of this method of infection in a case of gonorrhœal salpingitis. But this is not the only source of infection. For instance, in Case 2 it is more than probable that the suppurative process in the ovaries was due to contamination from the vermiform appendix, which was found in a condition of the most acute inflammation and so adherent to the wall of one of the cysts as to be apparently embedded in it. It will be noticed that in two of the cases fæces made their appearance in the discharges from the abdominal wound during convalescence: in one case on a single occasion only, in the other (Case 6) during thirty successive days. The liability for temporary fæcal fistulae to occur after abdominal opera-

tions where the intestines have been seriously involved in the adhesions is well known. It is due to the ease with which the intestine gives way when its wall is rendered soft and friable by inflammation and its external support is lost by the removal of parts to which it has been adherent. Under such circumstances the strain produced by a fit of laughter or of coughing or the act of vomiting is quite enough to burst the bowel and permit the escape of flatus and fæces. Fortunately it is an exceedingly rare event for a fistula so formed not to heal spontaneously. It must not be supposed that the fact of there having been an escape of fæces in two out of the six cases is any real indication of the proportion of cases in which this accident ordinarily occurs, for these six cases were all of more than average difficulty and severity and the intestines in most of them participated to a more than usually serious extent in the general pelvic inflammation. One important lesson brought home to us by these histories is the wonderful tolerance of the peritoneum. The peritoneum may be soiled by the spilling of fetid pus and even by the passage of fæces over it for many days together without injury, provided ample means of exit exist by which the offensive material can be quickly got rid of by the intra-abdominal pressure. In every one of the six cases purulent material escaped more or less freely into the peritoneal cavity, owing to rupture of the thinner and more densely adherent portions of the cyst wall during the process of separation, and in no instance did any constitutional harm result. Again, in Case 6 fæces passed over the peritoneal surface for thirty successive days without any perceptible ill effects. It may be said, in reference to the bursting of the cysts, that it was the subsequent irrigation that prevented injury. I am a profound believer in the value of flushing of the peritoneum, but I cannot think that it is effectual to the extent of washing the surface absolutely clean. It is, in my opinion, sound practice to ensure free subsequent drainage for at least some hours whenever pus has escaped, so that any portion that may remain after the flushing and sponging may find an easy way out. The powerful force of intra-abdominal pressure is then usually quite equal to the task of effecting its expulsion. For the same reason free drainage should always be provided when there is the least ground for fearing the escape of the intestinal contents. If they are thus provided with a means of exit they will avail themselves of it without delay and the danger of peritonitis will be avoided. Another lesson taught by these and similar cases is that the method that was here adopted of removing the cysts entirely is infinitely to be preferred to that of merely emptying and draining the abscess cavity and then stitching the cyst wall to the edges of the abdominal incision. The presence of the most formidable adhesions ought not to deter the operator from attempting the more complete operation.

### SOUTH DEVON AND EAST CORNWALL HOSPITAL, PLYMOUTH.

#### TWO INSTRUCTIVE RENAL CASES.

(Under the care of Dr. CLAY, Mr. WHIPPLE and Dr. PRANOE.)

BOTH these cases are important, as the real cause of the patient's serious condition was in Case 1 not diagnosed until the disease was very advanced; in Case 2 the kidney was never considered to be the primary cause of the patient's serious condition. In Case 1 death occurred whilst the patient was still under the influence of the anæsthetic, which was A. C. E. mixture; chloroform had been given at first, but when the patient was anæsthetised A. C. E. mixture was administered instead. The patient became convulsed and cyanosed and pulseless in a few seconds. She had never had fits during her childhood or pregnancy. The left kidney presented the appearance of a pyonephrosis due to calculus, the renal structure had entirely disappeared and the walls of the abscess cavities were quite smooth. The ureter was very thick, but its lumen was small. The pelvis was very much altered and filled up with fibrous tissue. In Case 2 there was nothing during the latter part of the patient's life to lead one to suspect kidney trouble. No tumour could be felt in the loin and nothing was found in the urine. Post-mortem examination showed how it was his condition was overlooked. The ureter was blocked; the abscess cavity had emptied itself, partly into the colon, and partly had made its way into the base of the right lung, where acute miliary tuberculosis had been set up. In both of these

cases there was well-marked compensatory hypertrophy of the other kidney, showing that if the diseased kidney had been removed there would still have been enough renal tissue left to be compatible with life. For the account of these cases we are indebted to Mr. A. Stanley Thomas, house surgeon.

CASE 1 (under the care of Dr. Clay and Mr. Whipple).—F. W.—, aged twenty-nine, married, was admitted on April 12th, 1892, with the following history. Two months previously she had been delivered at full term of a stillborn child. She had enjoyed good health throughout her pregnancy, except during the last two weeks, when she suffered from pains in her legs. She got over her confinement very well and was up and about on the fourteenth day. After that she began to suffer from pain in the left side, which was thought to be due to pleurisy, but not until a month later did she notice anything amiss, when she found that the left loin was very swollen. The urine was examined, and was said to contain pus.

On admission she was extremely thin and pale and looked very ill. Temperature 101°F.; pulse 130. She complained of pain in the left hypochondriac region, which was markedly swollen and extremely tender. Dulness extended in the left flank from the seventh rib in the mid-axillary line downwards to the crest of the ilium; behind, it extended from the vertebral column forwards to within three fingers' breadth of the umbilicus. The swelling was very tense and no fluctuation could be obtained. Urine was acid; sp. gr. 1014; it contained abundant phosphates, no albumen or pus, and nothing was found by microscopic examination. No increase in frequency of micturition.

On April 13th her condition was much the same; temperature 100.4°. She had passed twenty-four ounces of urine in the previous twenty-four hours. It was acid; sp. gr. 1014; no pus. On April 14th, her temperature having been between 100° and 102° since admission and her condition having in no way improved, she was recommended to have the swelling in the left loin explored. That afternoon she was given chloroform; when fully under the influence of this anæsthetic A. C. E. mixture was given throughout the rest of the operation. An incision parallel to the last rib was made in the left loin and very offensive pus was evacuated. A second abscess cavity was then opened above the first and similar pus escaped. Both cavities were irrigated with boracic-acid solution and a large drainage-tube was put into both cavities and the wound was then dressed with carbolic-oiled gauze and wood-wool wadding. The administration of A. C. E. mixture had been stopped for quite a minute when the patient, who had been breathing well all through the operation, became quite suddenly convulsed and cyanosed, the pupils became dilated and the radial pulse, which had previously been good, suddenly ceased and the patient never regained consciousness in spite of every restorative means being applied.

At the post-mortem examination, which was unfortunately not a complete one, the capsule of the left kidney extended from the brim of the pelvis upwards to the seventh rib. In front the colon and small intestines were adherent. The kidney substance was replaced by abscess cavities, the walls of the cavities being smooth, the contents thick fetid pus. The pelvis of the kidney and the perinephritic tissue were extremely thick and the opening into the ureter was very small, but the lumen was not at all dilated. The sac and the remnants of the kidney weighed one pound two ounces. The right kidney weighed eight ounces and was quite a healthy hypertrophied organ.

CASE 2 (under the care of Dr. Franco).—R. E.—, aged thirty, a labourer, was admitted on March 9th, 1892, with the following history. About a year ago he began to suffer from pain in the back and in the legs; he got gradually weaker, but not until early in February of this year did he take to his bed. On March 2nd he had his chest aspirated and a small quantity of pus was withdrawn from the right side. He had no history of any urinary trouble, and there was no history of phthisis in his family.

On admission he was very emaciated and complained of pain in the right side of the chest. He had a very troublesome cough; his expectoration was very offensive, but rather scanty. There was dulness over the right base and diminished vocal fremitus. On auscultation, fine râles and bronchial breathing were heard over this area. Respiration 22; temperature 98.8°. On palpating the abdomen nothing could be felt; patient complained of pain in the back; urine high coloured; sp. gr. 1014, acid; albumen present; no pus or blood. Microscopic examination revealed nothing. There

was a superficial abscess over costal cartilages on the right side.

On March 10th the abscess was opened below the twelfth costal cartilage. It contained gas and most offensive pus. Its cavity ran upwards between the liver and diaphragm. It was washed out and a drainage-tube put in, and then dressed with carbolic oiled gauze and wood-wool wadding.

March 11th.—Had a better night. Has lost all pain in right side. Dressed. Breathes through the opening beneath the twelfth rib. The patient's condition was now thought to be due to an empyema, which had perforated the lung and diaphragm.

12th.—Not so well. Will not take any nourishment.

14th.—Bowels were opened three times. Motions very offensive and liquids resembling pus.

15th.—Patient became comatose and died early this morning. At the post-mortem examination the incision made beneath the twelfth rib communicated with a perinephritic abscess. This abscess had extended upwards between the diaphragm and liver, the former had been perforated and the surrounding lung tissue was consolidated and affected with miliary tubercle. The rest of the right lung was normal, except that there were a few small calcareous nodules at the apex. The left lung also had signs of old tubercle at the apex. The abscess sac was adherent in front to the colon and had ulcerated into it in one place; the colon contained pus similar to that found in abscess. The right kidney weighed 10½ oz. and on section it was found to be riddled with abscesses, the walls of which were rough and irregular; and the contents varied from caseous material to thick yellow pus. The upper part of the ureter was dilated; five inches from the bladder it was kinked or twisted and at this spot the lumen was completely blocked. The left kidney weighed 12 oz. and was composed of quite healthy kidney tissue. There was no other sign of tuberculous disease.

## Reviews and Notices of Books.

*A Text-book of the Practice of Medicine for the Use of Students and Practitioners.* By R. C. M. PAGE, M.D., Professor of General Medicine and Diseases of the Chest in the New York Polyclinic; Visiting Physician to Randall's Island Hospital, St. Elizabeth Hospital, the Polyclinic Hospital, and the North-Western Dispensary Department of Diseases of the Heart and Lungs; Member of the New York Academy of Medicine and the New York Pathological Society, &c. New York: William Wood and Co. 1892.

We do not think that we can do better than quote the substance of some remarks from the author's preface to this work in order to describe its nature, design and general scope. He says that the chief objects in preparing the volume have been to facilitate clinical instruction and enable both the physician and student to obtain in brief the most practical as well as scientific view of the various subjects treated in it. Students in medical colleges and those who visit New York and other medical centres for the purpose of taking a supplementary course in clinical medicine, as well as the busy practitioner, often find that they have not sufficient time at their command to sift out desired information on any given subject from extensive treatises and systems. While such books are necessary and invaluable, it is believed that a shorter work is called for and will prove a valuable aid. Only the chief points in pathological anatomy, for instance, are given, and if further study in this direction is necessary recourse must be had to works specially devoted to the consideration of such subjects. On the other hand, the author has gone more fully than usual into detail regarding treatment, not only naming the drugs found useful but in many instances giving the prescription and dose. It is unquestionable that such books have their use, and the busy practitioner must frequently apply to a practical and compact work in which he can obtain the information he needs in a concise and condensed form, together with such methods of treatment as have been practically tested and

approved. It would be obviously unfair therefore to compare this work, as regards completeness and variety of information, with such treatises as the Dictionary of Practical Medicine by Various Writers, edited by Dr. J. Kingston Fowler, for example; but Dr. Page has succeeded on the whole in his Text-book of the Practice of Medicine in attaining the objects he has set forth in his preface. The book is illustrated, divided into eight chapters, and supplied with a table of contents, and a fairly sufficient, though short, index. The first chapter deals with Diseases of the Heart and Blood-vessels, and the information seems to be well put together and clearly set forth in the sixty-eight pages devoted to this subject. The chapter on Diseases of the Respiratory Organs is full. We notice that the author does not regard croup and diphtheria as one and the same, but as utterly different and distinct diseases. The symptoms of the former are those of catarrhal laryngitis, until stenosis takes place, when they are the same as those of diphtheritic croup. The one disease is a croupous inflammation of the mucous membrane of the larynx prevailing in certain damp, low-lying places exposed to north-east winds, and never infectious or contagious and not usually attended with the more severe constitutional symptoms and swelling of the lymphatic glands accompanying diphtheria. The author's description of and remarks upon pulmonary emphysema are to the point. We are glad to observe that he devotes attention to fibroid phthisis as a separate form or variety of chronic phthisis, but there is reason in Sir A. Clark's objection to its being regarded as invariably tuberculous (bacillary) in nature. The remarks on pleurisy with effusion and empyema are practical and sound. Diseases of the liver are fairly well described, but the description of suppurative disease of that organ is very meagre. In his chapter on Acute Infectious Diseases the author treats in a condensed and practical way of typhoid fever, and has some judicious remarks on the utility of giving large doses of quinine as an antipyretic. He alludes to the failure of large doses of ipecacuanha as a remedy in acute dysentery as the result of their experience of it in Bellevue Hospital in 1868; but we are glad to notice that he adverts to the use of aperients in the early stages of the disease, in which, by the way, he appears to have an earlier recourse to opium and to have greater faith in an opium treatment than the experience of others would indicate. The part devoted to Diseases of the Nervous System is not so full, scientific, and precise as could be desired.

As our readers will have already gathered from our remarks, we regard Dr. Page's book as a good digest of the practice of medicine. It is written in an easy, natural style and the author's aim has evidently been to aid the practitioner in recognising and treating the various diseases he may be expected to encounter in the practice of medicine as it exists to-day.

*Microscopical Observations on the Hematozoon of Malaria, with an Appendix containing a Series of Plates of Illustrations and Descriptions.* By Surgeon PATRICK HEHIR, M.D., F.R.C.S. Ed., Lecturer on Pathology and Clinical Medicine to His Highness the Nizam's Medical School and at the Afsul Gunj Hospital, Hyderabad.

In this monograph the author endeavours to do for malaria in India what has been done for it in other countries. After describing the methods and instruments employed and mentioning that 3281 slide preparations of malarial blood were examined (of which 1490 were from fifty cases systematically and daily examined from the date of entrance into hospital to the date of discharge, cured), Dr. Hehir goes on to describe the various parasitic forms met with; of these he mentions spores, small amoeboid organisms, spherical bodies, hæmatomonas malarie stellata, intra-corporal bodies, crescents, hyaline bodies, spores, rosettes and amoeboid bodies, flagellated organisms and

various pigmented and phagocytic cells. He then gives a description of these various forms and an account of their development. The author agrees with Dr. Vandyke Carter that visible blood contamination may be more constant and uniform than concurrent pyrexial phenomena, and from this he argues that such contamination is fundamental, whilst the fever is rather a contingent event. He considers that the hæmatozoa of malaria have a local destructive influence on the red blood cells, but that they set up fever "by the action of some poisonous substance, possibly a ptomaine, acting as a stimulant upon the heat-generating centres." He also maintains that there is no excessive formation of leucocytes and that the pallor of the blood when drawn is due to a decrease in the hæmoglobin present in the red corpuscles. Quinine does not effect the immediate dissolution of the organism, although it frequently arrests the recurrence of the fever, "showing that the action of the quinine is not altogether direct on the parasite, or at least not directly lethal." The plates, though rough and in one case somewhat eccentric, indicate fairly well the author's ideas of the appearances presented by these organisms.

*Les Anomalies Musculaires considérées au point de vue de la Ligature des Artères.* Par L. TESTUT, Professeur d'Anatomie à la Faculté de Médecine de Lyon. Paris: Octave Doin. 1892.

THE arterial anomalies which are of importance to the surgeon have been fully described in such works as those of Quain, Tiedemann and Henle, and it is most exceptional that any undescribed deviation is now observed which can in any way affect the procedure of the surgeon who has had a fair experience in the dissecting-room and who is at all familiar with anatomical literature. In these works and in scattered papers and monographs by other anatomists some other anatomical peculiarities which have a direct bearing on surgical practice are pointed out, and the frequency of their occurrence often noticed, but muscular irregularities have been more especially studied from the standpoint of the morphologist or the comparative anatomist than from their relations to practical surgery, although this has not been altogether neglected. Professor Testut has therefore done a great service to the practical surgeon who may at any time have to ligature an artery in its continuity by pointing out in a serial order these various anomalies in so far as they affect the ligature of the different arteries and thus filling up, as he truly says, a serious omission in our text-books on operative surgery. The large arteries which he has found to be occasionally covered by supernumerary muscular bands of surgical importance are the brachial, the axillary, the subclavian, the internal mammary, the popliteal, the posterior tibial and the peroneal. As an example of the method in which the author deals with the subject we may refer to the ligature of the subclavian at the base of the posterior triangle. He points out that after cutting through the skin, platysma myoides, superficial and deep cervical fascia, the operator may come upon numerous muscular bundles running in different directions which are not mentioned in ordinary works on practical surgery or most of the students' text-books on general anatomy. These bundles may be due to a forward extension of the trapezius on the clavicle, to a clavicular attachment of the omohyoid or to the existence of a cleido-occipital, a levator claviculæ, a supra-clavicularis or to supernumerary fibres of the sterno-hyoid. Each of these varieties is discussed in detail and the same plan is followed in the case of the other arteries. The author has met with no muscular anomalies which would affect the ligature of the carotids, the radial or ulnar, the iliac, or the femoral or the anterior tibial, and has therefore left them out of consideration. The small quarto of forty pages, published at 8 francs, is illustrated with twelve plates showing forty-one

varieties. These are excellently drawn in chromo-lithography and are mostly taken from Professor Testut's own dissections; they will well repay the scientific surgeon who devotes a little time to their study so as to supplement that everyday anatomical knowledge which is usually considered to suffice.

*A Practical Treatise on the Diseases of Women.* By T. GAILLARD THOMAS, M.D., LL.D. Sixth Edition, Enlarged and thoroughly Revised by PAUL F. MUNDÉ. London: J. & A. Churchill.

DR. MUNDÉ has performed a by no means easy duty fairly well, having recognised the difficult nature of bringing out a sixth edition of the "Practical Treatise" of Dr. Thomas, who, however, granted to the reviser the power to change, omit or add to the original text. This book has long been regarded, especially in America, as one of the most important text-books of the diseases of women on account of its clearness and apparent simplicity. In this edition we have a work combining the experiences of both these distinguished gynecologists, for all the chapters have been largely altered, many of them entirely rewritten, and several new chapters have been added. Great advances have been made since the last appearance of this work in 1881, and we naturally expected to find in this edition more in the way of recording facts than in retaining many of the speculations which encumbered previous editions and in this we have not been disappointed. We think, however, that in some chapters too much of the old matter has been retained; for instance, we find five pages occupied with the subject of the employment of tents, to which is added a short note by Dr. Mundé indicating that Dr. Thomas's present opinion is that "tents of all kinds should be discarded in gynecology, absolutely and completely" and rapid dilatation should always be practised by preference. Dr. Mundé, however, would be sorry to part with the tupelo tent where slow dilatation is required. In the preface it is stated that the work is designed for students and general practitioners, but owing to the differences of opinion sometimes expressed, as on page 491, in describing the treatment of pelvic peritonitis it must be rather difficult for a student to discover the principles underlying the prescribed treatment, seeing that the interpolated notes signed by Dr. Thomas and others more or less contradict the statements bearing the initials of Dr. Mundé. It is upon the whole an excellent treatise, but we consider that in many parts it is too verbose, and that if Dr. Mundé had acted on the authority given him by the author and omitted certain passages it would have been a more acceptable book both to students and to busy practitioners. The work is well got up and the illustrations, numbering 347, are beautifully executed.

*Darwin, and After Darwin.* An Exposition of the Darwinian Theory and a Discussion of Post-Darwinian Questions. By GEORGE JOHN ROMANES, M.A., LL.D., F.R.S. I. The Darwinian Theory. London: Longmans, Green and Co. 1892.

THE present treatise, the author tells us, has grown from two courses of lectures delivered at the University of Edinburgh and at the Royal Institution. These two courses resembled each other in comprising between thirty and forty lectures, but differed largely in other respects; and seeing that the present treatise has grown much beyond the bulk of the original lectures, it has been deemed desirable to publish the whole in the form of three separate works. The first, dealing with the purely historical side of biological science, stands over for an indefinite time; the second is the one now brought out and is devoted to the general theory of organic evolution as this was left by the stupendous labours of Darwin; and the third portion will follow (probably in the autumn season) under the sub-title

"Post-Darwinian Questions." It scarcely needs saying that the work, when completed, promises to afford the most comprehensive survey of the whole subject up to the latest date, from the hands of one of the ablest, most logical and most original of the exponents of the doctrines of Darwinism. This second part dealing with the Darwinian theory consists of 460 pages and is profusely illustrated. That which is to follow on Post-Darwinian Questions will probably demand extended notice, but we do not think that this part calls for any long criticism from us. All acquainted with the author's name and labours will be prepared to find that the facts connected with organic evolution are well arranged and lucidly stated, so as to evolve and lead up naturally and not arbitrarily to the line of reasoning and conclusions he has to set forth. Mr. Romanes says that as the present volume is simply intended to be a systematic exposition of what may be termed the Darwinism of Darwin and is likely to be of more service to general readers than professed naturalists, he has been careful to avoid assuming even the most elementary knowledge of natural science on the part of those to whom the exposition is addressed. Although this may be quite true, and the style adopted is as simple, precise and clear as practicable, and technical expressions have been for the most part avoided, still it has not been possible to do so altogether. The book requires much clear-headed intelligence and continuity of attention on the part of the general reader, who must be possessed of a good deal of elementary knowledge, scientific aptitude and "a love of the thing," if he is thoroughly to appreciate all the facts and the cogency of the reasoning—in the chapter on embryology, for example.

The introductory chapter contains some brief but excellent allusions to the subjective and inductive methods of research, to the revolt since the sixteenth century against the former and the disproportionate value assigned to Bacon's share in the movement, and to what the author terms the bugbear of speculation, which led to the idea that science ought to consist in a mere observation of facts or tabulation of phenomena without any attempt at theorising upon their philosophical import. The minds of naturalists were more or less bound and tied by the chain of these traditional notions, touching the severance between the facts of natural history and the philosophy of it, until the publication of the "Origin of Species" in 1859 set them free. It was in this, as in so many other respects, that it was an epoch-making book. Darwin was the Newton among naturalists, and in his eyes the value of facts was due to their power of guiding the mind to the discovery of principles. He was eminently painstaking and candid, with a sagacity in observation, a penetration in the interpretation of facts and phenomena that amounted to genius. Not facts or phenomena, but causes and principles are the ultimate object of scientific quest. To his predecessors the discovery or accumulation of facts was an end, to him it was a means; and the importance of Darwin's method of scientific speculation and of his exposition of the evidences of organic evolution as a fact and of natural selection as a cause were not circumscribed within the limits of a study of natural history. They had other and far-reaching influences. The late John Stuart Mill, for example, was not a naturalist, but a philosopher, and yet, indirectly, what a difference there would probably have been in his speculative methods of treatment of many subjects if he had lived and commenced to write after, instead of before, Darwin's doctrines had been propounded and investigated as they have now been.

Mr. Romanes shrewdly points out that some naturalists of the present day who have grown up in a Darwinian environment have more or less thoughtlessly adopted some form of Darwinian creed of a dogmatic kind, which, while it usually incorporates the main elements of Darwin's teaching, still more usually comprises serious perversions of their consequences. Be this as it may, Darwinism is only

concerned with the origin of particular forms of life—the origin of species. The theory of descent starts from life as a *datum* already granted, about the origin of which science is not at present, and possibly never will be, in a position to furnish so much as a suggestion. It deals with the evidences of evolution and the scientific theory of natural descent—continuity in natural causation.

The second and third chapters deal with Classification and Morphology and are clearly written and well illustrated. Chapter IV. on Embryology we have already alluded to. Chapter V.—Paleontology—is very well done and interesting, and is naturally followed by one on Geographical Distribution. The two serve to illustrate the general law laid down by Mr. Wallace that “every species has come into existence coincident both in space and time with a pre-existing and closely allied species.” The second section is devoted to the theory and evidences of natural selection and to a consideration of the criticisms on that theory, and the last chapter treats of sexual selection with concluding remarks. An appendix, together with notes and a good index, completes the volume.

The book is an able one and seems to be clearly, candidly and philosophically written; it contains a large amount of interesting and curious information and it is well illustrated, many of the illustrations being quite new. We can only add that we have personally derived both pleasure and profit from its perusal.

## New Inventions.

### NEW CLINICAL THERMOMETER.

FERRIS'S “Perfect Non Plus Ultra” Clinical Thermometer has no contraction in the stem and no chamber to contain superfluous mercury, consequently the whole of the mercury gets thoroughly warmed at once and the temperature is not only recorded more accurately than before but in half the time. The divisions and figures are brought down close to the bulb, so that without increasing the length of the instrument the scale of the thermometer is rendered nearly twice as open as before and is much more easily and accurately read. Ferris's “Perfect Non Plus Ultra” clinical thermometer has a permanent magnified index and a certificate of corrections ascertained by comparison with the standard instruments at Kew Observatory. The Kew corrections are marked on the stem of every thermometer.

## THE ASSOCIATION OF FELLOWS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE annual general meeting of the Association of Fellows of the Royal College of Surgeons of England was held at 5 P.M. on the 30th ult. at the rooms of the Zoological Society, 3, Hanover-square, W. Mr. T. Holmes, Vice-President of the Association, took the chair, and in expressing his regret for the unavoidable absence of the President of the Association, Mr. George Pollock, said that Mr. Pollock had been obliged to leave town on that day for the purpose of attending the funeral of Sir William Aitken at Netley. The minutes of the last annual meeting having been read and confirmed, the hon. secretary, Mr. Percy Dunn, stated that he had received upwards of fifty replies from Members of the Association respecting the postcard which had been issued announcing the annual general meetings, the annual dinner and the candidature of the nominee of the Association, Mr. John Tweedy, for a seat on the Council of the Royal College of Surgeons. Nearly all these replies were expressive of regret at being unable to attend the meeting and of determination to support Mr. Tweedy at the election on the 9th inst. A telegram to a similar effect from Mr. Mayo Robson was also read. The hon. secretary read the auditors' report, which was received and adopted, a balance in favour of the Association being shown.

Mr. Holmes then delivered an address reviewing the proceedings of the Association as comprised in the report which

has been recently issued to its members as well as to the Fellows of the College generally. Amongst other things he dwelt forcibly upon the inexpediency of the action of the Council of the College in coming to a decision upon subjects important both to the Fellows of the College and to the profession at large without consulting their constituents. Such matters, he said, ought to be discussed publicly at the College by the body corporate in the face of the profession and ought not to be decided secretly by twenty-four Fellows in an upper room. He instanced especially the scheme for coöperating with the University of London in examining for degrees and also the scheme for the fulfilment of the five years' curriculum. Referring to a recent assertion that the Association of Fellows was a political body, he repudiated it altogether and said that the Association had nothing whatever to do with politics. The Association had to meet a hostile feeling in certain quarters, but always conducted its business with the strictest regard to the feelings of those who were opposed to it. Mr. George Jackson moved and Mr. J. J. Purnell seconded the adoption of the report and this was carried unanimously. Mr. Alban Doran moved a resolution pledging the Association to use its utmost efforts to secure the return of Mr. Tweedy at the ensuing election at the College. He observed that many able men, after election to councils, never succeeded in understanding procedure and never gained a fair knowledge of by-laws. All who had served on the councils of Societies were aware of this fact. Yet, in order to make a good councillor, skill in procedure and a full knowledge of by-laws were imperative. Mr. Tweedy was one of the very few persons who had a full knowledge of the intricate Charters and by-laws of the College of Surgeons and his ability at public meetings was well known. He would prove a valuable addition to the Council. The resolution was seconded by Dr. W. J. Collins and carried unanimously.

In thanking the meeting for the resolution just passed in his favour Mr. Tweedy said that, as was well known, he had been reluctant to come forward as a candidate, but that he had acceded to the request conveyed to him because he took the warmest interest in the success of the Association, whose only object was to secure the best form of government at the College of Surgeons.

The election of officers for the ensuing year was then proceeded with. Mr. Rivington moved that the present officers and members of the Committee of the Association be re-elected and that the names of Mr. T. B. Kectley, Mr. George Jackson of Plymouth, Mr. Vincent Bell of Rochester, Mr. George F. Helm of Cornwall and Mr. Purnell of Streatham be added to the committee. Vacancies had been created by the decease of Mr. William Adams of Regent's-park and the retirement of Mr. Lawson Tait. It was desirable that the committee should be as representative as possible and it was a great advantage to have Fellows from different parts of the country serving on the committee. It had been suggested to him that he should give an account of his stewardship at the College, but it would be very inexpedient and improper to “reveal the secrets of the prison house.” He could not go beyond the published minutes of the proceedings of the Council. From these it would be gathered that progress was being made. Some might desire that the Council of the College should advance rather faster and less like the traffic on a suburban line, but everything now depended on the Fellows themselves. A most important concession had been made by the Council of the College—viz., that meetings of Fellows apart from the Members would be called for consultative purposes whenever the Council thought it desirable and also on a requisition from a certain number of Fellows. This concession was the cardinal point in all reform and if properly utilised would lead to all the other concessions which the Fellows of the College as a body might think desirable. The motion having been seconded by Mr. J. E. James of London was put to the meeting and carried unanimously. A vote of thanks to the chairman terminated the proceedings.

The annual dinner of the Association took place in the evening at the Criterion. Mr. Wm. Allingham occupied the chair. The attendance was curtailed in consequence of the alteration of the date of the dinner originally fixed for the 23rd ult., the Oxford and Cambridge cricket match, and the funeral of Sir Wm. Aitken. The chairman gave the usual loyal toasts and proposed “Success to the Association.” In responding to the toast of “The Association Candidate,” Mr. Tweedy gave an interesting account of his connexion with the reform movement at the College. The proceedings did not terminate till after 11 P.M.

# THE LANCET.

LONDON: SATURDAY, JULY 9, 1892.

SCARLET FEVER is causing anxiety in the metropolis by reason of the large number of attacks removed to the hospitals of the Metropolitan Asylums Board; and it is not unnaturally assumed that this exceptional number of hospital patients indicates a corresponding excess of scarlet fever amongst the population. If we were to consider fatal attacks alone, the cause for anxiety would not be so great. Thus, the largest weekly numbers of scarlet fever deaths in London during the past month were 29, 28, and 21 respectively in the three weeks ending June 18th, June 25th, and July 2nd, these exceeding the average by eleven, nine, and four deaths for the weeks in question. This is in itself not especially alarming. Still there is cause for anxiety in the fact that we have only just entered on the period when scarlet fever usually commences its seasonal rise. So far as attacks apart from fatal cases of scarlet fever are concerned, there does not yet exist much information as to seasonal activity; but Dr. WHITELEGGE, dealing with 23,000 attacks in nine large towns where compulsory notification existed, has shown that a very rapid rise has commonly set in towards the end of July, that it has continued to increase during the months of August and September, and that the maximum has been attained in mid-October, after which date a distinct decline has set in. During the twelve weeks ending June 25th over 5000 cases of scarlet fever were notified in London, the weekly number of attacks ranging from about 350 to somewhat over 550; and not only so, but the number notified during the last few weeks of that period exceeded by over 100 those notified in the previous four weeks. We are therefore, whilst only at the beginning of a critical seasonal period, in face of a substantial increase in the number of scarlet fever attacks. What this may mean it is at present difficult to say, for the reason already given, that we have no trustworthy experience as to the significance of attacks apart from deaths on which to base any precise opinion.

Another element of uncertainty lies in the circumstance that an amount of isolation in hospital is in progress such as London has never before experienced, and that this isolation is going hand in hand with administrative measures of prevention exercised by the local authorities such as have never before been practicable. During the month of June some 2100 to 2200 fresh cases of scarlet fever were certified, and we now learn that no less than 2460 cases were under isolation in the hospitals of the Asylums Board at the beginning of the present month. This is a remarkable achievement, and if we could believe that all attacks are notified and that the average detention of the patients in hospital was for a period of some six to eight weeks, it would mean that considerably more than one-half of the scarlet fever patients of London have been removed from localities where they would otherwise have become centres of infection, it being largely those

who are better circumstanced in this respect who have been allowed to remain in their own homes. And this is not all. Disinfection of rooms and clothing very generally follows removal to hospital, and much the same measures are adopted in other attacks on the recovery of the patients. Such measures are becoming more and more general, whilst notification provides means of information as to where these measures can and ought to be applied, which has not formerly been available. Further, notification in the metropolis is followed by information to school authorities as to the danger involved in allowing children from infected houses to associate with fellow pupils in school. This measure must be expected to remove a principal means of infection which has hitherto prevailed. Indeed, our experience of scarlet fever prevention under the existing circumstances of the metropolis are such that a forecast becomes unusually difficult; and the measures of isolation now available both in London and at the Gore Farm Camp, to which some 600 convalescents can be removed, give us reason to hope that we have means at hand which may enable the authorities to cope, as they have never done before, even with so rapid a rise in the number of attacks as marks this very critical period of the seasonal activity of the disease.

We cannot close these remarks without uttering a warning. When scarlet fever is thus generally prevalent it becomes a habit to look upon every fresh extension of the disease as one which is taking place in the commonly accepted method by aerial diffusion from person to person, assisted, perhaps, by the infection contained in the clothing of those who have been attacked. There have, however, been several recent occurrences of the disease which have seemed strongly to indicate that milk was serving as the vehicle of the infection. One excellent report has been issued on this subject by Dr. J. KING WARRY on an outbreak in Upper Clapton which was said to be associated with the distribution of milk; and other local prevalences in the metropolis have raised suspicion that the same process was going on elsewhere. Under these circumstances it is of the utmost importance that a careful watch should be kept as to the conditions of health and disease in dairies and milk-shops, and that every health officer and sanitary authority should be on the lookout for possible distribution of scarlet fever through the agency of milk. This leads to a further consideration. The Clapton outbreak, to which we have just adverted, could not be traced to any infection of the milk from a human source; and the milk alleged to have been the vehicle of conveying the disease was found to have been derived from a dairy where exceptional precautions as to health and cleanliness were habitually observed. But some of the cows were found to be ailing, the actual ailment at the time of their examination being essentially limited to cracks and abrasions on their teats, with abnormally high temperatures. Past experience compels the utmost caution as to minor ailments, so-called, in milch cows at such a juncture; and it may be well to consider, quite apart from the spread of scarlet fever through its ordinarily recognised channels when once established, whether such seasonal activity as we are now experiencing as regards the affection in the human subject does not in some measure, at least, find its source and its means of rapid diffusion in a bovine ailment, the

prevalence of which is equally favoured by certain seasonal and climatic influences at this period of the year.

DURING the present week two subjects widely differing in their character, but both of paramount importance, have engrossed the attention of the good citizens of Dublin, the burgesses being engaged in the selection of fit and proper candidates to represent them in Parliament, and academicians in their efforts to do fitting honour to the celebration of the tercentenary of the University of Dublin, identical with its own college, that of the Holy Trinity, popularly known by its familiar name, Trinity College. Whatever historic doubts may exist as to the source whence the "Virgin Queen" derived her inspiration, there can be none that the first letters patent were issued by QUEEN ELIZABETH on March 3rd, 1591, thereby winning for herself the proud title of "Fundatrix Collegii Sanctæ Trinitatis *juxta* Dublinum." The presence of "*juxta*" is a constant cause of surprise to those acquainted with the present position of the College in the very centre of a large and populous city, but unacquainted with its early history. Briefly it may be told how, outside the walls of old Dublin, in the possession of the then existing corporation, were some thirty acres of land which the corporation granted to the college for the erection of its buildings—a fact gratefully borne in mind on this the occasion of the commemoration of its tercentenary by the collegiate authorities; in evidence of which a grace of the Senate has been passed conferring the honorary distinction of LL.D. upon the present Lord Mayor of Dublin, and this compliment has been speedily reciprocated by the corporation conferring the freedom of the city on the present Provost, the Rev. Dr. SALMON. Partly by gifts of confiscated lands and partly, though in a minor degree, by purchase, the University is possessed of a considerable amount of landed property which is let on lease to tenants, who in their turn sublet their holdings. The college found this a satisfactory arrangement, as the "middle man" acted somewhat after the fashion of an agent and collected the rents, and the "middle man" obtained for himself satisfactory profits; but in recent times these profits have to a great extent disappeared, and in some instances have reached such a vanishing point that the direct tenant has surrendered his lease to the college authorities, thereby throwing upon them the onus of collecting the rents from the occupier of the soil. Nevertheless it is pretty generally believed that the collegiate income from this source alone reaches the sum of £50,000 a year, the remainder coming from students' term fees and fees payable for the various degrees.

In the University there are several "faculties," but that of medicine is naturally of principal interest to the medical reader. Until recent years the medical school was at a very low ebb indeed—a fact which can be easily explained. At the time alluded to the University would not recognise any certificates but those issued by its own professors for attendance on the lectures required from candidates who sought the degrees. As a consequence the College of Surgeons refused to recognise such certificates, and required their candidates to produce certificates emanating from other teachers recognised by themselves, so that the student seeking both qualifications had to pay twice over for

the required certificates. To the credit of the University it must be stated that it was the first to recognise this anomalous condition of affairs, and after a long struggle, carried on within the walls of the College of Surgeons, principally by the late Drs. BEATTY, ADAMS and HUTTON, and the present Professor RAWDON MACNAMARA, "free trade" gained the day. Since then the University has progressed by leaps and bounds and, thanks to the enlightened zeal and energy of the Rev. Dr. HAUGHTON, its anatomical halls and chemical laboratories have acquired a deservedly high reputation.

During many years it was the fashion to style Dublin University the "Silent Sister," but so far as medicine in the broadest sense of the word is concerned such a reproach was undeserved—witness the writings of GRAVES, STOKES, ROBERT HARRISON, WILLIAM HENRY PORTER, ROBERT ADAMS and CARMICHAEL, the productions of whose pens are classics in medical literature. We must, however, leave it to others to vindicate from this reflection the *alma mater* of USHER, MOLYNEUX, SWIFT, GOLDSMITH, BURKE, BERKELEY, "TOMMY" MOORE, CONGREVE and a host of *alumni* who have carved for themselves niches in the Temple of Fame.

We may briefly note the preparations made to do adequate honour to this important commemoration; it is obvious that the University itself acted in no niggardly spirit in this direction. So far as entertainments go, on the first day took place the garden party in the Fellows' garden; on the second day the tercentenary banquet in the Leinster Hall, to which something like a thousand guests were bidden; on the third day there was a dramatic performance in the Gaiety Theatre; the entertainments winding up, so far as the University is concerned, with the University ball to be held in the Leinster Hall this (Friday) evening. We must express surprise that the play selected for the dramatic performance was the "Rivals" of SHERIDAN, an author who had no connexion with the University, to the exclusion of the tender-hearted, generous to a fault, simple-minded GOLDSMITH, for the production of whose comedy, "The Good-natured Man," the occasion seemed to be singularly appropriate. Rarely played, it would have afforded no opportunity for invidious comparisons—no unimportant consideration when it is remembered that all the male characters are represented by amateurs, the female characters, however, being played by actresses from Mr. EDWARD COMPTON'S comedy company, at present fulfilling a short engagement in Dublin. Failing GOLDSMITH, why was CONGREVE overlooked, whose "Love for Love" would have had the charm of novelty and unsurpassed dialogue? An excellent prologue to the performance of "The Rivals" has been written by Mr. EDWIN HAMILTON. In addition to these entertainments several Honorary Degrees have been conferred in the various Faculties, the recipients of those in Medicine being H. R. H. DUKE CHARLES of Bavaria, Sir ANDREW CLARK, JOHN SHAW BILLINGS, THOMAS BRYANT, ADOLF GUSSEBROW, JONATHAN HUTCHINSON and GRAINGER STEWART, whilst the College of Surgeons, in honour of the event, conferred its honorary Fellowship on Messrs. BRYANT, BILLINGS, GUSSEBROW, and SNELLEN; the President, moreover, issued upwards of 750 cards of invitation to an "at home" to be held to-day (Friday), upon which occasion his Excellency will unveil the bust to be placed in the College in memory of the late lamented Dr. ROBERT MACDONNELL. On Wednesday their Excellencies gave a garden party at the Viceregal Lodge;

and on Thursday the Commander of the Forces gave one at the Royal Hospital, Kilmainham.

Immediately after the reception of the guests and delegates by the Provost in the Examination Hall, favoured by beautiful weather, a procession in full academic robes proceeded on foot to St. Patrick's Cathedral, to attend the commemoration service; and the crowds which thronged the streets witnessed a sight the like of which they are not likely ever to see again. The University of Dublin is to be heartily congratulated on the great success of its tercentenary commemoration.

THE reference in the Report of the Select Committee of the House of Lords on Metropolitan Hospitals and many subjects connected with hospitals deserves a more detailed notice than we were able to give it in one number. We propose, therefore, to deal specially with a few of these subjects as opportunity may offer. Of these one of great interest is the question of Poor-law infirmaries, their general administration and their medical efficiency. The older members of the profession will well remember the dismal provision for the sick poor in the old workhouses. Nothing could be more unsatisfactory. The nurses consisted of paupers a little less infirm than those whom they nursed. The equipment of the workhouses was deficient in all that goes to mitigate the severity of suffering. The scandal culminated in the case of TIMOTHY DALY who suffered from rheumatic fever in a London Workhouse and whose feet projected several inches beyond the edge of his bed. His death led to the investigations of THE LANCET into the general condition of the sick in workhouses, and these in their turn led to the memorable legislation of 1867 known as Mr. GATHORNE HARDY'S Act and the creation of the Poor-law infirmaries. The establishment of these institutions and of the asylums for infectious diseases created new ideas of the duty of the State towards its sick poor and has altered the feeling of reluctance with which such poor regard state assistance in the form of hospital treatment. Insensibly in twenty years a new set of twenty-four hospitals has grown up with 12,445 beds in them. Nor do we seem to have got to the end of this provision. Many of the workhouses, notably Bethnal Green, are without infirmaries; the sick in them are nursed largely by untrained or pauper nurses.

We are much interested in all the bearings, medical, educational and political of this great hospital system of Poor-law infirmaries. It exceeds already the voluntary hospitals in the number of its beds by about 4000. It is still indeed far behind in the quality of its nursing and in the quality of the medical service supplied to the patients. But having said so much on one side we have much pleasure in noting the high terms in which the Committee speak of the general management and the medical and nursing efficiency of these institutions. We regard this as distinctly creditable to the medical profession. The medical officer of these Poor-law infirmaries is not only the medical superintendent, but he is responsible for the general control of the whole establishment. This arrangement is of course open to the objection actually made that an officer who is responsible for the general control of an establishment with 700 or 800 beds,

with perhaps only one assistant, cannot have any leisure for the proper and adequate treatment of so great an amount of suffering humanity. We cannot deny the force of this argument. But it remains true that no serious faults have been exposed, that the general administration is good and that no complaint of neglect of the sick emerged in the course of the inquiry. We see in this another proof of the administrative faculty which abounds in the profession. It is well known that these institutions are served by many able practitioners, who strangely prefer the appointments with their limited incomes (varying from £300 to £500 a year) to the chances of general practice with its uncertainties, its unpaid bills and its rough and irregular work. All the same we are glad to see that the question of the sufficiency of the medical arrangements of these infirmaries was distinctly raised and that important suggestions have been made for its improvement. It requires little imagination to understand that a medical superintendent and one or even two assistants, with 700 patients on their hands, can have but little time to give to individual cases, and that such a number of sick must include many cases of difficulty, of danger, and of suffering on which the opinion of a medical or surgical consultant should be taken. The provision for such consultation should be systematic as it is in Birmingham. We are told in the Report that some superintendents admitted the necessity for some such provision. Some said it was allowed and paid for by their guardians; others said they found no difficulty in getting hospital surgeons and physicians to come and see such cases without fee. But it is due alike to the superintendents and to the patients that a regular provision for consultations should be made in some form or other. The Committee of the House of Lords are much impressed with the evidence in favour of turning the clinique of the poor-law infirmaries to account for the furtherance of medical education. They allege that there was a remarkable uniformity of evidence in favour of this and of the belief that such an arrangement would not be disliked by the sick; indeed that it would be positively beneficial to them. The Committee were told by many witnesses that it would tend to secure careful examination of cases, to discourage routine in treatment, and that the clinical experience to be gained in a Poor-law infirmary would be different from that of the general hospital, both in respect of its in-patients and out-patients. They ventured to suggest that the Poor-law infirmary appointments would especially be useful to men just qualified, or in the fifth year of their studies which has just been added by the General Medical Council. This proposal is not new. It has been repeatedly before the Medical Council. But, spoken of with so much favour by the Lords' Committee, it is sure to come into fresh and serious consideration. It is one of many proofs that with all their perfection our existing hospitals do not teach the student everything and all classes of disease. The exact way in which the Poor-law infirmary is to be brought into line for educational purposes with the hospitals or with general practice is a matter for much reflection. Such a step would of itself involve a reconstitution of the medical staff. We should sincerely regret any change that would affect the authority of the medical superintendents who have so well managed these institutions. But without doing this it will be possible to increase the medical staff to the advantage

of the patient and the relief of the superintendent, whose importance, we venture to think, would only be increased. We have only room for one more word in regard to these great Poor-law infirmaries. It is one of caution. There is a danger that these institutions may be made too easy and pleasant and so become pauperising. "It would seem," says the Committee, "that the excellence of the infirmaries and their separation from the workhouse are likely to exercise, and in fact do exercise, a distinctly pauperising effect on the poor." "Many patients are artisans in receipt of good wages." There should be no parsimony in dealing with actual pauperism associated with sickness, but there is a note of warning in these sentences of the Report against the encouragement of pauperism which we commend to the attention of all concerned.

whether the apparent increase of crime is not sufficiently accounted for by the increase in population. On this point Mr. MORRISON furnishes us with the following statistics—viz., "Basing our calculations upon the estimated population at the middle of each decade it comes out that in 1860-69 one case was tried annually for every forty-four of the inhabitants of England and Wales; in 1870-79 one case was tried for every thirty-seven inhabitants; and in 1880-89 one case was tried for every thirty-eight inhabitants." It would thus appear that crime has been almost stationary during the last two decades, but that these decades indicate a substantial increase on the previous one.

The quality of the crime is obviously a point even more important than the mere number of offences. Taking murder as the most important of all crimes, we find that in the decade 1860-69 the yearly average of murders reported to the police was 126; in 1870-79 the yearly average was 153; and in 1880-89 the yearly average was 160. Even allowing for growth of population there is here a substantial increase in the gravest offence known to the law. The average annual number of indictable offences, which was 2315 in the decade 1870-79, had risen to 2562 in the decade 1880-89. The annual average number of offences against property with violence, which was 1483 in the decade 1870-79, was 1850 in the decade 1880-89. The annual average of offences against property without violence had, however, shown a decided diminution. The number was 10,701 in the former decade, 8049 in the latter. This decline is attributable to the operation of the Summary Jurisdiction Act, which has removed many offences of this nature from the list of "indictable offences," and so this decline cannot be interpreted as indicating a real diminution in this variety of crime.

Facts tend strongly to show that the predisposition to crime is greatest in the greatest centres of population. Thus one policeman was required in the City of London and in the Metropolitan Police District for every 312 of the population as enumerated in 1881; in the English boroughs one policeman was required for every 697 of the population; in the counties only one policeman was required for every 1150 of the population. Mr. MORRISON draws from these statistics the conclusion that "where there is most civilisation there is also most crime." We entirely dispute the justice of this conclusion. Great cities cannot in any true sense be said to be generally and in all parts more highly civilised than the adjacent country districts. The slums and alleys of great cities furnish the deepest depths of barbarism to be found in the civilised world. Further, great cities are the great foci towards which gravitate the streams of thriftlessness, vice, vagabondage and crime. To say that because great cities furnish an undue proportion of crime civilisation tends to make men criminal is, it seems to us, to advance one of the most dangerous and disheartening of fallacies.

We may, lastly, look at the statistics of the prison population, although, as we have already pointed out, this is a very misleading gauge of the growth or decline of crime. The yearly average of persons committed to prison in the decade 1860-69 was 127,690, in 1870-79 it was 154,145 and in 1880-89 it was 170,827. These figures indicate not only an absolute increase in the committals to prison, but also an increase in proportion to the population. The figures

The short paper in the current number of the *Nineteenth Century* on "The Increase of Crime," by the Rev. W. D. MORRISON, raises one of the most important and also one of the most difficult of social questions. At first sight it might seem a very simple matter to determine whether or not crime is on the increase; in reality it is very difficult. With such important and clearly defined crimes as murder or manslaughter there is not much difficulty. The total number reported to the police, the number of trials, convictions &c., will afford a fairly satisfactory basis for calculation. But we are on very different ground when we seek to determine whether the criminal population is increasing or declining. The average number of persons in our gaols depends upon many conditions apart from a growth or decline in crime; depends, for example, on the activity or negligence of the police, on the severity or leniency of magistrates and other officers of the law, on the prevailing tendency to inflict long or short sentences, and lastly depends to a very important extent upon legislation. Crime is partly "natural"—i.e., there are some crimes that are universally recognised as such by all civilised men; but it is also partly artificial or law-made—i.e., an act may be criminal in one country that is not under legal ban in another. The Elementary Education Act of 1870 and the Criminal Law Amendment Act of 1885 added new offences to our Statute-book, and it is obvious that convictions thus arising could not be fairly reckoned in any comparative estimate of the prevalence of crime at the present day and at some past period. It is thus clear that the question is an extremely complex one and that criminal statistics must be scrutinised with the most jealous care before any confident conclusions can be drawn.

Mr. MORRISON first draws attention to the number of cases tried, whether summarily or on indictment, during the last three decades. The figures are as follows:—

	Yearly average of cases.				
1860-67	...	...	...	...	466,687
1870-79	...	...	...	...	628,027
1880-89	...	...	...	...	701,060

Here we are face to face with an apparent very substantial increase in crime. It is satisfactory, however, to learn that offences against the Elementary Education Acts alone account for more than half a million of cases during the last two decades. The question at once arises

for the reformatory and industrial schools show an even larger increase. The rapid and uninterrupted increase in the police force points in the same direction.

Mr. MORRISON concludes, first, that there is a very substantial increase in crime now in progress in our midst, and secondly, that this increase is almost wholly due to the excessive concentration of masses of population in large cities. Mr. MORRISON'S position and the painstaking attention which he has bestowed upon the elucidation of this important subject entitle his opinion to great weight; but before accepting his somewhat pessimist conclusions we should like to have some aspects of the subject treated which he has not dealt with, or at least not dealt with in a way to exhaust the discussion. For example, to crimes the rule is eminently applicable that for a just appreciation they must be weighed, not counted only; and Mr. MORRISON'S statistics appear to us open to cavil in this respect. Ten little crimes may testify to less depravity in a society than one great one; and until it is made out that the figures from which the writer's inferences are drawn are above the suspicion of equating unequal things, we shall be disposed to cling to the more hopeful view of the modern record of crime which other authorities than Mr. MORRISON are able to adopt.

#### THE INTERNATIONAL MEDICAL CONGRESS OF 1892.

THE opinion we have from time to time hazarded as to the month and week in which this great assembly should meet in Rome has just been confirmed at the last conference held *ad hoc* by the Comitato Centrale. We now know that the last week of September has been officially fixed as that during which the Congress will sit. That this is a matter of vital importance to the success of the meeting no one who is cognizant of the character of the Roman climate in the late summer and early autumn can fail to appreciate. Exaggerated though it be, particularly after the activity of the municipal rediles during the last twenty years in reclaiming outlying spaces and building over intra-mural tracts previously tenanted only by the malarian bacillus, the impression is still a prevailing one that from the close of June to the middle of September Rome is not a healthy place of sojourn—an impression reinforced by the immemorial usage of its inhabitants, who for that interval descend to the seaboard or go up to the mountains to escape the heat and the fever-laden breath of the Campagna. To invite the profession from all parts of the world to assist at the Roman Congress during the days of August would simply have been to court the refusal of nine-tenths of those whose presence might have been counted upon. In full cognisance of this the Comitato Centrale have been well inspired in their selection of the time of meeting, and though the last week of September has its drawbacks, particularly for those surgeons and physicians whose duties require them to be at their posts at the opening of our medical schools, still there is just enough interval between the rising of the Congress and the beginning of the winter session to allow of their assisting at the former and being not too late for the latter. We trust, therefore, that the decision of the Comitato Centrale, arrived at as it has been after much consultation of the convenience of the profession in two hemispheres and in many countries, will be found to collide with

no great number of "previous engagements," and to favour as far as possible the truly representative character of this greatest of international gatherings. "Little more than a year," writes an Italian correspondent, "separates us from the memorable occasion which will confirm Italy's right to sit among the nations who, with fraternal confidence in each other, labour in the name of science. The high importance of this approaching reunion has been recognised abroad not less than in the peninsula, inasmuch that while a powerful phalanx of the physicians and surgeons of the Alta Italia have sent in their adhesions the post brings a daily shoal of letters in which the leading lights of foreign medicine, the scientific academies, the associations, and the institutes of Europe and America announce with the most gratifying expressions of goodwill towards Italy their intention to come in person or to be worthily represented. In the next few days the Comitato Centrale will address an identical appeal to all the physicians of central and southern Italy, an appeal to which the response, I need not say, will be at once unanimous and enthusiastic." The Comitato Locali will before the month is out be not less numerous than those which have for some time been in working order in Lombardy, in Piedmont, in the Venetian territory and in the Emelia. The Italian Government, we may add, coöperates loyally and effectively with the profession in its endeavour to make the Congress as brilliantly successful as any of its immediate predecessors, and will, we trust, enable the great promoter of the gathering, Dr. Guido Baccelli, to complete the mighty undertaking of his life, the Roman Policlinico, in time to show his brethren from abroad how Italy can and will improve upon her memorable past in pathological research and in therapeutic resource. To have crowned the edifice of such an institution in presence of the grandees of medical science and medical art will more than entitle the eminent consultant, who is not less distinguished as a patriot than as a physician, to say "Vixi" and to enhance the pride with which he will echo in Rome the welcome that greeted the profession on the façade of the Congress Hall at Berlin, "Universi Medici Orbis Terrarum Salutamini!"

#### MEDICAL AID SOCIETIES AND THE PROFESSION.

OUR correspondence columns have recently afforded evidence not only of the great and very natural interest taken by our readers in the subject of the bonds into which the medical officers of friendly societies are commonly required to enter upon taking up their appointments, but also of the serious hardship which the observance of the covenanted conditions not seldom entails. It is easy to understand that in a discussion of this kind the disputants should be led to adopt strong views, and in no way surprising if they should be betrayed into expressions of opinion not altogether warranted by the facts or the law, as the case may be. This has, we believe, happened in the course of the discussion which has recently occupied our columns. Some of our correspondents have opined that engagements which would prevent a man from practising on his own account in the neighbourhood in which he has practised as an officer of the medical aid society are in no way binding and may be cast to the winds when the opportunity of infringing them arises. Now if this were sound law it would be very questionable morality, and if adopted as a line of conduct from the first would be such as no casuistry could justify. It may well be that a man who has been tricked or coerced into a position which he never intended to take up, but into which he has been forced either without his knowledge or in spite of his protest, may feel himself at liberty to accept any means of escape which the law extends to him. But any man who should sign an invalid bond knowing it to be invalid and intending, if occasion should arise, to

take advantage of the flaw, would be guilty of dishonourable conduct which no technical justification could excuse or palliate. We think, therefore, that the legal question is not of the importance which some of our correspondents have been inclined to attach to it. The only way in which, without stooping to unworthy shifts, a medical practitioner can defend himself against imposition is by resolutely refusing to undertake any obligations which he will not, when the time comes, be prepared honourably to discharge. But while we adopt this higher ground of morality as that upon which a question of this sort should be decided we have reason to think that some of our correspondents have seriously misapprehended their legal position. We understand that it is quite possible for a bond to be drawn which will bind a man not to take away from an institution with which he has been connected the patients with whom he has there been brought into contact, and which in furtherance of this undertaking will shut him out from practice within a reasonably defined area. Whether a particular bond will or will not be effectual for this purpose must of course depend upon its terms, and if any of our readers who may have such bonds in their possession will furnish us with copies for publication we shall be happy to obtain a legal opinion upon their effect for the benefit of the profession at large. The matter is undoubtedly of great importance, and it would be well for all parties that the legal position no less than the ethical questions involved should be elucidated by full and sufficiently informed discussion.

#### THE PROGRESS OF CHOLERA.

CHOLERA has made some further and substantial progress in South-Western Russia. At Baku on the Caspian the outbreak is of considerable dimensions, and no less than ninety-one deaths, took place there on July 2nd. The port of Petrovsk and the town of Astrakan at the mouth of the Volga have also been invaded, the western shore of the Caspian being thus attacked at three different points. South of the Caucasus the number of places invaded has also increased, and at the present moment Tiflis, Elizabetopol, Shamachi, Erivan and Shusha are seats of the disease. Another line of extension is up the Volga, and this is the more ominous because this is the season of the year when a large traffic up this river commonly sets in. The towns of Tzaritzin and Saratov have already been attacked, and the province of Samara, which immediately abuts on that of Saratov, is also stated to have suffered from such attacks. One of the greatest dangers to Europe will lie in extension of the disease to Black Sea ports, from whence, notwithstanding the restrictions that may be imposed, there will be risk of infection to such European ports as Odessa. In the meantime the Sanitary Board at Sofia has ordered ten days' quarantine upon vessels arriving at Bourgas, Varna, and Balchik from Russian ports in the Black Sea between Soukham Kale and the Turkish frontier. In Russian Turkestan and Bokhara the disease is still maintained, but whilst it has distinctly diminished at Meshed no other serious extension has taken place. On the other hand certain journals in the Caucasus announce that the disease has broken out in the neighbourhood of Bagdad in Mesopotamia. The news which we publish from our special correspondent as to cholera in Paris is disquieting. That form of disease which we are wont to style English cholera often prevails in large centres of population during exceptionally hot weather and Paris has suffered from such weather. Severe diarrhoeal diseases also tend to supervene when sewage-polluted water is being consumed and some parts of Paris and its outskirts are now receiving Seine water which must be regarded as contaminated by sewage. But neither of these conditions is as a rule associated with anything like

the mortality which is persistently maintained around Paris, except when either true cholera or severe enteric fever are the causes of it. According to M. Monod, the energetic Director of Public Health for France, the prevalence to which we advert caused 159 deaths during the three months ending June 30th; it is mainly confined to the loop formed by the Seine west of Paris, and it is positively declared that no case of exotic cholera has taken place. This view has, up to recently, been also supported by Dr. Proust. To these high opinions, if still maintained, we feel bound to defer; but, on the other hand, we believe we are right in saying that the special districts referred to are not the only ones which have received Seine water during the recent drought; that the interior of Paris, where there has been no similar outbreak, has had some share of the same water; and that the mortality is of quite an exceptional character even for the localities attacked. When twelve and fourteen diarrhoeal attacks terminate fatally day by day in a limited area and the disease is not infantile diarrhoea the circumstances of such fatality are sufficient to cause apprehension. Aubervilliers, one centre of the epidemic, has traditions of true cholera which are by no means remote, and, in addition to that district, Courneuve, St. Denis, La Plaine, Ile St. Denis, Suresnes, Courbevoie, Asnières, Clichy, Rueil and Colombes have also been seats of the disease. We trust that the measures which are being taken to prevent further diffusion of the outbreak will be successful and that the inhabitants will take the advice offered to them and boil all potable water so long as it may be necessary to draw it from the Seine. The recent occurrence of alleged cholera on board the *Crofton Hall*, which had to return to Calcutta in consequence of the mortality amongst its crew, has turned out, as we anticipated, to be an outbreak of ptomaine poisoning from unwholesome meat. This is the decision at which Dr. Simpson, the city health officer, and Dr. Forsyth have arrived. We are glad to be able to state authoritatively that, notwithstanding rumours and statements to the contrary, no case of Asiatic cholera has occurred in the Port of London, or, indeed, in any part of the metropolis.

#### MEDICAL PRACTITIONERS AND THE GENERAL ELECTION.

It is certainly a somewhat unique occurrence for a body of medical men to interview a candidate for parliamentary election, with a view to ascertaining whether he is sound on important topics in which they are interested. "Tempora mutantur, nos et mutamur in illis." In these days, when every profession and separate interest has come to press forward its claims on the attention of Parliament, those who are too backward and modest to do so are apt to be forgotten and neglected. It may be owing to this, to some extent, that the medical profession has never received that honourable recognition and distinction from Parliament to which it is so justly entitled from the eminent services it incessantly renders the nation and from the learning and ability of its members. Hence we cannot but highly commend the action of the medical practitioners of Bradford who waited on Mr. Byron Reed, one of the candidates for Parliament in that borough, and laid before him some important questions on which they wished to know his opinions before the polling-day. The action of the deputation was all the more praiseworthy seeing that, following the high traditions of our profession, they sought rather to gain benefits for the public than merely to forward their own particular interests. It is true they uttered a protest against legislation which has recently singled them out from the rest of the population and placed them under penal obligation to render services to the public for which in some instances they receive no remuneration. Medical practitioners are not State officials. If the State

wishes to reap the fruits of medical science it must require the services rendered. The most obvious way of doing this would be by assisting the profession in the acquisition of that knowledge which the State is now coming to see is indispensable to the well-being of the public and by protecting medical men in the practice of their profession. The subjects which Dr. Hime, as the chief spokesman, referred to are of importance and the deputation deserves credit for having drawn public attention to them. A report of the meeting will be found in another column.

#### THE REPEAL OF THE CONTAGIOUS DISEASES ACTS.

THE *Admiralty and Horse Guards Gazette* of the 25th ult. contains, under the heading "Free Trade in Disease," a most able article showing the evils which have resulted from the repeal of the Contagious Diseases Acts, and especially as regards the increase of disease among the men of the army and navy, both abroad and at home. The article deals most severely, but not unjustly, with those persons of both sexes to whom the country owes the repeal of those Acts. Fortunately, the issue is now changed. When the Acts were in force it was contended that all the improvements attributed to the Acts were due to other causes. But now that they have been repealed disease is more rife than ever and is increasing in such a ratio that the attention of the authorities must soon be called to the fact. Whatever may be the political constitution of the majority of the new Parliament and whether the present Ministry will remain or a new one be formed, it will be the duty of some member in the interests of the army, navy, and civil population to call the attention of the House of Commons to the disastrous results of the repeal of the Acts and to ask for an inquiry thereinto. Whether this should be by a committee of the House of Lords or the House of Commons or by a Royal Commission need not be just now discussed. For the present it is gratifying to see that our appeal has been responded to and that a representative of the lay press has taken the matter up, and that we are not left with our medical contemporaries to fight the battle alone. We trust that other representatives of the lay press will exert their power and influence in a cause which does not merely concern soldiers and sailors, but everyone who has at heart the welfare of his fellow-creatures.

#### A GREEK MEDICAL WORK 2000 YEARS OLD.

IN the last number of the *Classical Review* Mr. F. G. Kenyon, of the British Museum, who last year edited the newly discovered papyri of Aristotle and Herondas, describes another similar manuscript recently obtained for our national collection, which contains an ancient treatise upon Medicine by a Greek author, probably of Alexandria. The work, which has apparently hitherto been lost, is of much interest, and the following *résumé* of the state and contents of the manuscript condensed from Mr. Kenyon's report will indicate its importance. The papyrus is of tolerable size, measuring twelve feet, and bears thirty-nine columns of writing, each about three inches in width. Towards the end the writing is more compressed and the concluding portion, which comparatively contains the largest amount of matter, is fortunately in exceedingly good condition, but the other parts of the papyrus are both torn and rubbed and the text frequently barely legible. As to the treatise itself, the first eighteen columns are devoted to quotations from earlier writers as to the origin of diseases and present to us so many quotations from Greek medical authors of the earliest times that if the text can be tolerably well restored it will prove most valuable. Among the writers cited are Euryphon of Chidus, Herodicus, Hippocrates, Timotheus of Meta-

pontum, Philolaus of Croton, Polybius and Menicrates, Dexippus of Cos, Petron and Phillistion, and Alcamenes. In quoting from some of these writers the author tells us he obtained their extracts from a work of Aristotle. Mr. Kenyon suggests this was not an authentic work of that philosopher, but the one cited by Galen, as bearing his name, which was really written by his disciple Menon, and thinks it probable that much of this papyrus text is derived from Menon's work. These quotations appear to cease with authors of the fourth century B.C., and then the more original part of the work is taken up. Unfortunately, just here the writing is very defective, but it can be gathered that much importance is attached to an explanation of the rival views of Herophilus and Erasistratus. The latest author quoted is Alexander Philalethes, who flourished towards the termination of the first century B.C., and the omission of all reference to Galen would seem to show that the recovered treatise was written originally before his time, though this papyrus may be a later edition. It is to be hoped that some of the medical societies may undertake to assist a competent scholar to edit this work, the funds of the British Museum being more properly applied to the acquisition than the publication of such treasures.

#### INFANT INSURANCE AND INFANTICIDE.

WE will not dispute the fact that there is an essential difference between child insurance and baby farming. The distinction, however, it is to be noted, consists in many cases mainly in a primary intention which has now become obsolete. For lack of any visible proof to the contrary we are forced to the conclusion that practical issues must explain the true purpose in either case and thus the terms are commonly found to be really interchangeable. A fresh illustration of their close relationship was afforded by a case recently decided. The defendants, a man and his wife, became possessed of an infant presumably illegitimate some four months ago and received with it a maintenance allowance of £20. The husband took out a policy for the child. Then followed a period of neglect, starvation, disease and general misery, mercifully terminated by the infant's death. To our mind, and especially in view of the history of many similar cases, there is an evident suggestiveness in the association of circumstances here noticeable.

#### THE RECENT BALLOON ACCIDENT.

THE public will hardly be satisfied with the conclusion come to at the official inquiry as to the cause of the fatal balloon accident on June 29th—namely, that no blame attached to anyone. The fact of a disaster having occurred need not, of course, imply intentional neglect, but it certainly could not have taken place under conditions of weather believed to be entirely favourable without some oversight. An examination of the evidence teaches us that as far as is known there was no fault in the original construction of the balloon or in its general management after it ascended. On a previous occasion the aeronaut, Mr. Dale, narrowly escaped a similar fall from the unexpected opening of the valve. This does not seem to have occurred on the present occasion. A part of the neck of the balloon had to be repaired before the ascent, but neither does this fact suffice to explain the accident. The only possible clue to its cause obtainable thus far is connected with the material structure of the balloon. We are told that it was not new, that it was made of cambric, that after the previous ascent it had been wetted, oiled, rolled up and put away; and that when unfolded for use on the last occasion it felt hot. In the fact just mentioned we may probably trace, if not the actual progress of chemical change, at least an assisting circumstance. Moisture and heat are allowed to act for a week upon a quan-

tivity of oiled cambric and decomposition inevitably follows. The question is whether such decomposition would so soon rot the structure as to explain the fatal occurrence. No other but an affirmative answer is, we fear, possible. The neck was not tied, and thus undue pressure by the gaseous contents upon the inflated bag was avoided. Here, however, another question suggests itself. Is it not possible that any dampness of this important part of the balloon could have impaired its efficiency as an exit for surplus gas? Whatever the answer to this query, the fact is clear that after rising some 600 feet the huge bubble burst either from excess of gas pressure or decay of its delicate envelope, or both. A further inquiry into the circumstances is clearly indicated. We would suggest that if instituted it should comprise a careful examination of the condition of the cambric used in this instance, and that it should be partly experimental. Some authoritative utterance as to the materials other than silk which are best suited for balloon construction and the methods of their management is evidently called for as a condition immediately affecting the safety of such ascents as that which has just ended so unhappily.

#### WOOLWICH AND PLUMSTEAD COMMONS.

THE military authorities who, as was stated in a recent issue of THE LANCET, had forbidden cricket and football on the whole of Woolwich Common except in one damp and irregular corner, have somewhat unexpectedly made an important concession which will add largely to the facilities the youths of the neighbourhood at present enjoy for their games. A strip of ground at the top of the common, near the Herbert Hospital, measuring nearly half a mile in length by perhaps 250 yards in breadth, is to be allowed to be used after mid-day—except on the rare occasions when it may be required for parades—on condition that the local board keeps order and sees that a few simple regulations are observed. The military authorities have also shown themselves desirous of meeting the needs of the youths who live a little further to the east by offering for games such portions of that part of Plumstead Common which is still under their control and is not actually required for the evolutions of the troops. Still further to the east a magnificent addition is just being made to the recreation grounds of the people by the opening of Bostall Wood, which will be under the control of the London County Council. In consequence of the facilities provided by the Woolwich Free Ferry all these open spaces, as well as the large tract of beautiful country round Shooter's Hill, Eltham, Chislehurst and the Crays are being more and more utilised for recreative purposes by the inhabitants of Mile End, Bromley, Bow and other parts of East London, who may be seen almost any morning now driving through Woolwich in brakes on their way to spend a "happy day" at some of the numerous rural resorts offered by the north-west corner of the "garden" county, which at the present time is at its loveliest.

#### THE ADVANTAGES OF BODILY EXERCISES.

IN the *Journal of the American Medical Association* for June 4th is an interesting paper by Dr. J. Madison Taylor on the Influence of Bodily Exercises upon Length of Life. He commences by enunciating two propositions: (1) That judicious activities of the body tend to maintain and increase its efficiency; and (2) that the hurtful effects of violent athletic competitions are popularly overrated. The first of these propositions is obvious and he therefore chiefly deals with the second. Against the growing interest in athletic matters there are constantly urged objections to the effect that many perfectly healthy young men are injured beyond repair by strains and shocks to vital organs received in the course of training or competitive sports, even among those who avow much confidence in the value of physical exercise; yet many

declare the pity of it because such havoc is wrought thereby. Instances are cited, rather vaguely it is true, of fine fellows utterly wrecked by contests on land or water, of lives cut short by overtasks at so-called sports. After pointing out how important it is for medical men to define and point out dangers and urgently insist on their avoidance in such cases, Dr. Taylor proceeds to argue that even the best and wisest of medical teachers can err in opinion and cites as an example an assertion of Dr. B. W. Richardson: "I venture to affirm there is not in England a trained professional athlete of the age of thirty-five who has been six years at his calling who is not disabled"; and the same author as saying: "When the artificial system of training ceases, the involuntary muscles, the heart especially, remain in strength out of all due proportion greater than the rest of the active moving parts of the organism." Dr. Taylor maintains that this authoritative statement has swayed the judgment of thousands of thinking men. He has had these views on the damage done to involuntary muscles quoted to him again and again. Such cases he considers are indeed possible and from such causes do they come in the laborious ranks of iron-workers and those who put forth in long days excessive and continued muscular exertion. Among professional athletes the heaviest strains must come, as upon the output of the most concentrated force alone comes to them honest reward. Dr. Taylor has collected the brief histories of a score of these men now living which he thinks at least illustrate how vigorous and sound such men may be even long after the age limit which Dr. Richardson has assigned to them. These histories are interesting and some of them very remarkable and Dr. Taylor is strongly of opinion not only that the judicious pursuit of bodily exercises, either in the line of ordinary avocations, special duties, or sports, tends greatly to maintain and enhance the vigour of both body and mind, but also that the hurtfulness of severe muscular exertion short of profound exhaustion is merely temporary and recoverable and that dangers to internal organs and vital centres are comparatively rare.

#### TREATMENT OF PHTHISIS BY CREASOTE AND GUAIACOL.

DR. F. P. KINNICUTT, in delivering the Middleton-Goldsmith Lecture for this year in New York,<sup>1</sup> chose as his subject "New Outlooks in the Prophylaxis and Treatment of Tuberculosis." He considered very carefully the various methods of treatment which had lately been introduced and gave his experience of those he had tried. One of the most interesting series of records are those cases treated by creasote and guaiacol. Dr. Kinnicutt wished to test the practicability of employing a very large daily dosage of the creasote preparations and to determine, if possible, any advantage which this method might possess over their use in smaller quantities. Several of the patients selected for this treatment presented in a well-marked degree many of the symptoms—namely, hectic sweats &c.—attributed to the toxic influence of the products of the bacillus and were therefore well adapted to test the effect of creasote upon such manifestations. A tabulated report is given of seven cases which were treated with subcutaneous injections of guaiacol, rapidly pushed to a daily dosage of one gramme, and five cases with creasote by the mouth, also rapidly increased to *six grammes* daily. In four of the former cases there was little, if any, appreciable change in the physical signs of disease. In one of them, however, the general condition greatly improved and there was a gain in weight of eight pounds; in one the weight decreased by one pound and three-quarters, in one there was a loss of four pounds, in one the weight remained stationary; in the three remaining cases there was a progressive increase of the pulmonary

<sup>1</sup> Boston Medical and Surgical Journal, May 26th, 1892.

lesions. No influence upon hectic, when present, was observed. Night sweats, however, were affected favourably. In a single case suffering from chronic nephritis (confirmed by necropsy) a marked increase in the albuminuria was observed when a daily dosage of one gramme was reached. The treatment was then discontinued and the albuminuria gradually diminished. In no other case treated either with guaiacol or creasote did any trace of albumen appear in the urine, although examinations were made every other day. In a single case, where the maximum dose of guaiacol was reached, the urine became dark in colour and very similar in appearance to urine containing carbolic-acid products. In the cases treated with creasote two exhibited no appreciable difference in the physical signs. In those there had been a gain of one pound and a loss of three pounds respectively. In the three remaining cases there was a progressive increase of the lesions. The effect of a very large daily dose of creasote upon hectic sweats corresponded to that noted in the use of guaiacol. Entire tolerance of six grammes (over one and a half drachms) of creasote was exhibited by three of the five patients. One complained of slight gastric discomfort when a daily dose of five grammes was reached. Carbonate of guaiacol was also tried. In addition to possessing the advantage of being tasteless and odourless, it seemed to have a beneficial effect on the appetite. The conclusions which Dr. Kinnicutt formed from a careful study of these cases were: That both creasote and guaiacol in certain forms could be given in very large doses with entire tolerance and without injurious effect; that such doses apparently possessed no advantages over much smaller ones and had no greater effect upon hectic and night sweats; that subcutaneous injections of the drug possessed no advantages over administration by the mouth; that whatever beneficial influence creasote might exert in pulmonary tuberculosis could be effected with a comparatively small dosage; and that favourable results could be expected only by its continuance and prolonged employment.

#### THE RESTRAINT OF JUVENILE SMOKING.

It is time that the attention of all responsible persons should be seriously directed to the prevalence and increase of tobacco smoking among boys. Here and there, as we have recently shown,<sup>1</sup> there have been observed expressions of a strong repugnance existing in the public mind against this form of juvenile perversity; but we still lack the support of a general and outspoken objection to its continuance. At the same time we feel assured that no man who has really given any thought to the matter would hesitate in condemning the injurious folly of this practice. Stunted growth, impaired digestion, palpitation and the other evidences of nerve exhaustion and irritability have again and again impressed a lesson of abstinence which has hitherto been far too little regarded. A further stage of warning has been reached in a case which lately came before the coroner for Liverpool. A lad was in the habit of smoking cigarettes and cigar ends, and after an attack of sickness died somewhat suddenly. The post-mortem examination revealed fatty changes in the heart, which there was little doubt, as the verdict held, had been fatally supplemented in their influence by the smoking habit referred to. This of course is an extreme example. It is also, however, after all, only the strongly coloured illustration of effects upon health which are daily realised in thousands of instances. Not even in manhood is the pipe or cigar invariably safe. Much less can it be so regarded when it ministers to the unbounded whims and cravings of every heedless urchin. Clearly there is need of some controlling power here. The parent in certain classes is almost as ignorant of consequences and

probably often quite as apathetic as his boy. Where he can be roused to the active exercise of his authority in repression he should be. In very many cases he cannot, and we have therefore no hesitation in asserting once more our conviction that it is incumbent upon the Legislature, in view of its known pernicious effect upon mind and body during boyhood, to restrict this habit by an age limit which will fall outside this period.

#### CARLILL v. THE CARBOLIC SMOKE-BALL COMPANY.

To those among our readers who are familiar with the ways of the quack medicine vendor the facts proved the other day by Mrs. Carlill in the action which she brought against the Carbolic Smoke-ball Company will occasion no surprise. It seems that the company, which trades in a commodity called the "carbolic smoke-ball," had offered, as an inducement to the public to patronise their shop, a guarantee of £100 that any person using their nostrum should enjoy thereafter immunity from influenza. Mrs. Carlill took the advertisers at their word, bought and used their prophylactic and thereafter suffered, like many of her unprotected neighbours, from an attack of influenza. The promise of immunity having thus been falsified the lady brought an action to enforce the alternative promise of a solatium of £100 and was met with a defence which put forward every possible ground of technical objection to the plaintiff's claim. We are glad to learn that in spite of the ingenuity of their legal advisers the defendants have been held liable to make good their promise. People who are silly enough to adopt a medicine simply because a tradesman is reckless enough to make extravagant promises and wild representations as to its efficiency may thank themselves chiefly for any disappointment that ensues. Still for this folly, which is only foolish and nothing worse, it is possible to feel sympathy when the disappointment comes. It is a pleasant alternative to learn that the dupe has been able, as in the present instance, to enforce a sharp penalty and that the process of reaping a harvest from the simplicity of one's neighbours is attended with dangers of miscarriage which must materially diminish its attractiveness in the eyes of those people who supply the popular demand for quack medicines.

#### CHOLERA IN KASHMIR.

CHOLERA, which existed in several parts of the Punjab during April, was imported into Kashmir along 200 miles of hill road by the men engaged to transport grain to Gilgit, on the frontier. It began in the city of Srinagar in the beginning of May and increased with such rapidity that within fourteen days the deaths per diem from cholera rose from 5 to 50 and then to 150; during the next fortnight the mortality steadily increased till the daily average was 270, even mounting to 300. At the date of our last advices it was slowly decreasing. About 350 new cases were being daily reported, with 140 to 150 deaths. Nearly every part of the city has thus been literally decimated. Within a month 4500 deaths have been registered. The disease is now spreading into the villages, but in a less virulent form. Several European visitors have been attacked and 6 have died. The State Medical Department has exerted itself to the utmost under Dr. A. Mitra in dealing with the cases. Dr. Thomas of the Mission Hospital is dangerously ill at present. He had been much overworked in the house-to-house visitation of the sick. There was a severe epidemic in 1888, when 10,000 patients died. So long as Srinagar remains perhaps the dirtiest city in the world such outbreaks are to be expected. The lesson to be learnt is that sanitation is less costly than epidemics. It is to be hoped that the British officials who are the responsible advisers of the Maharajah will take this lesson to heart. The

<sup>1</sup> THE LANCET, May 14th.

Government of India is responsible for the very expensive frontier policy of Kashmir. But for this large sum of money now spent on the army would be available for works of public utility, such as roads, drainage and a pure water-supply, all of which are now conspicuous by their absence. Surgeon-Colonel Harvey has gone to Kashmir to investigate the question of sanitary reform. It is to be hoped that the Indian Government will see to the resolute carrying out of his suggestions.

#### BROMIDE OF ETHYL AS AN ANÆSTHETIC.

BROMIDE of ethyl has been somewhat extensively employed in Vienna for anæsthetic purposes. In Professor Billroth's clinic it was used 300 times without mishap. Death, however, subsequently occurred in the case of an out-patient who was about to have a very large boil on the arm incised. While anæsthesia was being induced in the usual way the man suddenly became cyanotic and the respiration and cardiac movements ceased. Artificial respiration was persevered with for an hour and a half, but was of no avail. At the post-mortem examination there were found adhesions in both lungs; the heart was fatty and easily torn. The microscope showed that there was fatty and parenchymatous degeneration of the liver and kidneys as well as of the heart. There was no hyperæmic condition of the brain as in death under chloroform. It would seem, therefore, that whatever anæsthetic had been employed the patient might have died; so that no serious degree of blame can be attached to the bromide of ethyl.

#### MR. WATTS' GIFT TO THE NATION.

MEMBERS of our profession will be interested in learning that Mr. Watts, the eminent painter who intends to present to the nation a collection of his works, is now engaged on the picture which is to complete that collection. A short time ago he required medical advice and a well-known consultant was called to see him. The latter diagnosed his patient's case, prescribed for his relief and after some conversation was about to leave the room. Mr. Watts leant forward in his bed and said to the consultant, "Stay a moment—I should like a word with you. I have almost completed the collection of pictures which, as you are aware, I am about to present to the nation. There is but one picture wanting to complete the collection. I have had that picture in my mind for a long time, but I have not had the opportunity of seeing the subject of it until to-day. I want to paint you and when I have done so the collection for the nation will be complete." The gentleman addressed expressed his appreciation of the honour and we have no doubt that the profession generally will concur in this appreciation, seeing that the consultant in question is so representative a member of the body medical as the President of the Royal College of Physicians—Sir Andrew Clark.

#### THE WATER-SUPPLY OF CROMER.

THE Cromer Waterworks Company, in view of the growing popularity of the town, have been engaged during the past two years in sinking a second well capable of giving a supply considerably in excess of that hitherto available. These wells are situated more than half a mile away from the town. Owing to the sandy character of the upper strata great difficulty was experienced in sinking the new well, which varies from 8 ft. to 5 ft. in diameter, and has been carried to a depth of 183 ft. from the surface. The chalk was reached at a depth of 138 ft. below the surface, and, with the object of ensuring the purity of the supply by excluding all percolations from the strata above, the well has been lined to a depth of 151 ft. with brickwork and iron cylinders. The new borehole, which is 20 in. in diameter, extends from the bottom of the well for a further depth of 40 ft. Two head-

ings, each 6 ft. by 4 ft., have been driven a distance of 100 ft., one serving as a connecting link between the new well and the old borehole by means of which the town has hitherto been supplied. The permanent water-level in the new well and the old borehole is 110 ft. from the surface and, as already stated, all the water flows directly from the chalk. The well, with the headings, possesses a storage capacity of about 25,000 gallons and the total yield when the works are in full operation will be at least 200,000 gallons a day, a supply that will suffice for the requirement of the town for many years to come, even at the present rate of progress. A new set of pumps and engine has been erected, which is designed to lift 12,000 gallons per hour, and the entire system is now in duplicate, so that in the event of a breakdown—an eventuality by no means likely to happen—a failure in the supply will, practically speaking, be an absolute impossibility. The water has recently been examined by Professor Frankland, F.R.S., and he reports on samples taken from each well as follows: "The two samples are of most excellent quality for dietetic purposes. They are absolutely free from all evidence of previous sewage or animal contamination, whilst for chalk water they are of very moderate hardness. Cromer may be congratulated on being supplied with one of the best waters in Great Britain." The works have been carried out under the direction of Mr. J. C. Melliss, M. Inst. C.E., of London, and by Messrs: Thomas Tilley and Sons of Walbrook, London. The pumps and machinery have been supplied by Messrs. Robert Warner and Sons of Walton-on-the-Naze, while the buildings at the surface have been erected by Mr. John Newman of Cromer.

#### FORCIBLE REMOVAL TO INFECTIOUS HOSPITALS.

THE case which recently occurred at Fulham and in which a patient was ordered by the magistrate to be removed to the fever hospital on the certificate of Mr. Cooney and against the opinions of Dr. Cayley, Dr. Phillips and others, is likely to be an important one in the history of sanitary legislation. Lord Sandhurst speaks on this subject with much authority, being chairman of the Middlesex Hospital and having been chairman of the Select Committee on Metropolitan Hospitals. Lord Sandhurst has called attention to the facts in the House of Lords, as reported at length in last week's issue of THE LANCET, and in the course of his remarks said that the board of the charity (the Middlesex Hospital) had promptly taken the case into consideration and passed a vote of confidence in Dr. Cayley. His lordship also quoted Sir Andrew Clark as to Dr. Cayley's standing in the College of Physicians and his high authority on such a question as the diagnosis of fevers. Lord de Ramsey, replying on behalf of the Government, said the case was one calling for the supreme control of the Home Office, by which it is understood an inquiry will be made into all the facts of the case. At Fulham a crowded public meeting has been held to express sympathy with the mother of the patient. Resolutions were passed tendering thanks to Dr. Cayley and Dr. Phillips and requesting the Local Government Board to cause a public inquiry to be made into the case, also asking whether the magistrate's interpretation of the Public Health Act does not place far too much power in the hands of medical officers and medical men in general, and whether there is not urgent necessity for an amendment of the law as regards the notification of infectious diseases. The fine of £10 and costs was remitted by the Home Secretary after Lord Sandhurst had made him acquainted with the facts of the case. Though the facts of this case raise questions rather as to the judgment with which the law has been administered than as to the law itself, yet it is well worthy of consideration whether some greater security for sound diagnosis in doubtful cases must not be provided than the certificate of any one practitioner would imply. Indi-

vidual and domestic liberty are sacred things. But the public safety is still more so. The important thing in every serious invasion of private and domestic liberty is to eliminate as far as possible the element of fallibility and to give the poor, who are mostly affected, the same security as the rich. It is only by these means that popular respect for such legislation can be maintained.

#### THE ORGANISATION OF SCIENCE.

WE have received a disclaimer from "A Free Lance" with regard to our criticism of his "Organisation of Science."<sup>1</sup> He is willing that the Linnean Society, whose carnivorous tendency, though contrary to the law of specialism, he appeared to sanction, should deliver up its fauna to its junior, the Zoological Society. His only wish is to further by special concentration of energy the fullest consideration of scientific problems. He also repudiates all intention of limiting by centralisation the vigour of intellectual enterprise. Nothing, therefore, could be more admirable than his purpose. While we gladly admit this however, we must express the opinion that it is one of the most objectionable, as well as most marked and essential, features of specialism, notwithstanding the nice accuracy of its accomplishments, that it tends to a progressive narrowing of the scope of the intellect and a restraint of its free energy, which has often proved fully adequate to the work of investigation in diverse lines of study. Neither would we forget that the very plan of natural subdivision seems to repudiate anything like pure specialism, since every individual department merges within the dim confines of some other.

#### THE DEATH OF THE PREMIER OF BRITISH COLUMBIA.

IN reference to the inquest held on the body of Mr. John Robson, Premier of British Columbia, on the 4th inst., the following particulars of the illness have been furnished at our request by Dr. George Ogilvie. Mr. Robson was sixty-eight years of age and had been suffering from overwork for some time. He came to London on business on June 20th and on that day, when riding in a hansom cab, the tip of the little finger of the right hand was crushed in the hinge of the door. The injured finger was at once dressed at Westminster Hospital and Mr. Robson was able afterwards to keep his appointment at the Treasury Office. The dressing was changed next day at the hospital. He did not again visit the hospital and did not obtain any further advice till he was seen by Dr. Ogilvie on the night of June 26th—i.e., six days after the accident. There had been a rigor on June 23rd, which Mr. Robson attributed to ague, and he did not attach much importance to it, although he felt ill. The following days he suffered from slight nausea and malaise. When first seen by Dr. Ogilvie he had the aspect of a patient suffering from a continued fever. The skin was moist, the complexion sallow, the tongue was glazed and the lips parched. The pulse was weak and irregular; respiration 28, temperature 102°. The physical examination of the thorax and abdomen disclosed nothing which could account for the symptoms. The dressing, which had a faint odour of iodoform, was removed from the finger. The finger nail was loose, the skin covering the tip of the finger was of a dirty-grey colour, and there had been fracture of the tip of the terminal phalanx. An opiate was administered and the patient passed a fair night. Next day the temperature rose to 104°, and Mr. Watson Cheyne was called in consultation. The finger was amputated the same evening. The temperature fell two degrees after the operation, but next day again rose to 104°. The pulse became rapid and intermittent, the respiration was shallow and more frequent,

the breath had a peculiar sweet odour, and the tongue became dry and furred. Later on the temperature fell to 100° and, coma gradually supervening, the patient died on the evening of June 29th—namely nine days after the accident. No post-mortem examination was ordered by the coroner and the family did not desire one to be made.

#### DEATH OF PROFESSOR BIERMER.

THE death is announced of Professor Anton Biermer, who until quite recently was Director of the Medical Clinic in Breslau. He had occupied himself with microscopic investigations, especially of the sputum, and he published papers on the metallic sound in auscultation of the lungs. Previously to his going to Breslau as successor to Lebert he had been Professor of Medicine in Berne.

#### DONATION BOXES IN OUT-PATIENT ROOMS.

WE should be glad to hear from many quarters as to the voluntary contributions of out-patients. At the anniversary court of the governors of the East Suffolk and Ipswich Hospital it transpired that the donation boxes in the out-patient rooms had been very ill supported, only 1s. 7d. being given by 4278 patients. There was a falling off, too, in the Sunday collections.

#### CHRONIC NITRO-BENZOL POISONING.

DR. WARFINGE of Stockholm has reported some cases of chronic poisoning by nitro-benzol occurring amongst workmen employed in a factory where this substance is used and where the workshops are small and badly ventilated. In one case which was treated at the Sabbatsberg Hospital there was severe headache during the first week, followed by lassitude and general debility with fatigue after walking. After some time retching and vomiting with great loss of appetite came on and the bowels became confined, the stools having a reddish-brown appearance. The urine, too, was reddish brown and of a syrupy consistence. There was depression and restlessness at night and subsequently a feeling of formication in the fingers and toes, which rapidly spread to the hands and legs. A blowing sensation was complained of in the feet, which appeared to affect the whole of the body. The headache became more severe and was accompanied by giddiness and impairment of vision with tinnitus in the ears. After this there were tremor in the upper extremities and impaired sensation in the upper and lower limbs with, for two days, impairment of the power of speech. The patient, after three months in the hospital, recovered sufficiently to enable him to resume his work in the factory, but after having been there for four months he was obliged to apply for readmission to the hospital, with somewhat similar symptoms to those existing previously. He presented much the appearance of a person with locomotor ataxy, but, after a month's treatment, recovered.

#### FOREIGN UNIVERSITY INTELLIGENCE.

*Berlin.*—An Extraordinary Professorship in the Philosophical Faculty has been conferred on Dr. Assmann, an eminent meteorologist, who was at one time a medical practitioner.

*Buda-Pesth.*—For the vacancy in the surgical chair caused by the death of Dr. Lumniczky the Professorial Senate have proposed the following names: *Primo loco*, Professor Dolinger and Professor Réczey; *secundo loco*, Professor Navratil; *tertio loco*, Dr. Hugo Schmidt of Pressburg.

*Greifswald.*—Dr. Stöwer has been recognised as *privat-docent* in Ophthalmology.

*Heidelberg.*—Dr. Fleiner, assistant in the Medical Clinic, has received an offer of a Professorship at Innsbrück.

*Prague (Bohemian University).*—An Ear and Throat Clinic

<sup>1</sup> THE LANCET, June 18th.

has been established of which Professor Emilian Kaufmann has been asked to take charge.

*Würzburg.*—Dr. Rudolf Arnim Fick has been recognised as *privat-docent* in Anatomy.

At the tercentenary celebration of the Dublin University on Wednesday last the honorary degree of Doctor of Medicine was conferred upon John Shaw Billings, Washington; Thomas Bryant, President R.C.S.; Sir Andrew Clark, President R.C.P.; Adolf Gusserow, Berlin; Jonathan Hutchinson, London; and Thomas Grainger Stewart, Edinburgh. The degree of Doctor of Sciences was conferred on J. Burdon Sanderson, Oxford; Michael Foster, Cambridge; Sir George Murray Humphry, Cambridge; Julius Kollmann, Basel; Alexander Macalister, Cambridge; Professor Richet, Paris; Sir William Turner, Edinburgh; Wilhelm Waldeyer, Berlin; and others.

The Italian Society of Laryngology, Otology and Rhinology will meet for the first time in Rome towards the end of October next. Among the agenda the following may be noted:—1. Report by Professor F. Massai of Naples on the Phases, Nature and Therapeutics of Laryngeal "Papillomi." 2. The Diagnostic Value of the Perception of Sounds "per la Via Craniense ed Aerea" (cranial and respiratory) in Maladies of the Ear. Reported by Dr. Corrado Corradi of Verona. 3. Diagnosis and Treatment of Affections of the Sinuses annexed to the Nasal Cavities. Dr. Giuseppe Strazza of Genoa, reporter.

The Khedive of Egypt has conferred upon His Excellency Crookshank Pasha, F.R.C.S. Edin., the Second Class of the Imperial Order of the Medjidieh in recognition of the valuable services rendered by him as Director-General of Prisons. The brevet and insignia of the 1st order were presented to Crookshank Pasha on the 21st ult. by His Excellency Ahmet Choucry Pasha, Under Secretary of State, and, at present, Acting Minister for the Interior, together with a letter from His Highness the Khedive.

A COMMITTEE MEETING in support of the "Sir George Buchanan Presentation Fund" was held on Thursday, July 7th, at 5.15 P.M., at 13, Old Burlington-street. Subscribers are reminded of the desirability of their sending in their subscriptions as soon as possible, in order that the committee may know at an early date the amount of the fund which will be at their disposal. Dr. W. H. Hamer and Dr. J. C. Thresh are the honorary secretaries.

The medical profession all over the world will learn with profound regret that Professor R. Koch of Berlin, whose researches have so greatly advanced our knowledge of disease, has of late been incapacitated from work and that there is grave reason to fear that the condition of his health is such as to preclude the resumption of his duties for some time at least.

The Rose Show and Floral Fête which was held at the Mansion House on June 24th and opened by the Princess Christian, accompanied by her daughter, Princess Victoria, was organised by the Lady Mayoress for the benefit of the Royal Hospital for Women and Children in Waterloo-bridge-road. After all expenses were paid the Lady Mayoress was able to present to the hospital the sum of £1050.

The summer dinner of the Irish Medical Schools and Graduates' Association took place on the 4th inst. at Kings-town, Dublin, Dr. Mapother presiding and fifty-one members and guests being present.

The University of Siena, by eighteen votes of its Senatus Academicus out of twenty-one, has just elected Professor Domenico Barduzzi as its rector. Dr. Barduzzi is one of the most distinguished among its clinical staff and takes an effective part in promoting the balneological resources of Italy.

The chair of General Clinical Medicine in the Istituto di Studi Superiori at Florence, left vacant by the death of Professor Federici, has by the unanimous vote of the medico-chirurgical faculty of the Institute, been offered to Professor Grocco of Pisa, a clinical teacher and consultant of high reputation in the latter seat of learning.

LORD REAY presided on Monday at a special meeting of the Royal Commission to consider the granting of a charter to the Gresham University for the purpose of hearing the opinions of M. Couvreur, a Belgian professor, who explained the methods of University education in that country.

MR. GEORGE JOHNSON, M.D., Physician Extraordinary to the Queen, and Mr. Frederic Bateman, M.D., Senior Physician to the Norfolk and Norwich Hospital, were introduced to the Queen's presence on July 5th and received the honour of knighthood.

The annual competition for the Volunteer Medical Association Ambulance Challenge Shield will take place at Wellington Barracks on Saturday, the 16th inst., at 5 o'clock. Those interested in the competition are invited to attend.

At the request of a number of his former students, Professor Grainger Stewart of Edinburgh has consented to sit for his portrait, which is to be painted by Sir George Reid, P.R.S.A.

## CHOLERA NOSTRAS AND THE PARIS WATER-SUPPLY.

(FROM OUR SPECIAL CORRESPONDENT.)

THOUGH prominent Government officials may consider it their duty to maintain that everything is for the best in the best of all possible worlds there is no denying that the epidemic in the suburbs of Paris is a matter of grave anxiety. We are asked to believe that there is no cholera; but to the numerous persons who have died after an illness of only a few hours it matters little whether the cause of their deaths was cholera nostras or Asiatic cholera. We are told, on the best authority, that already some hundred and fifty persons have died. To them, at least, the consequences were equally sudden and disastrous. The dejections of the patients have been examined; an official report was to be published as to the result. This report has not yet appeared. Why has it been held back? Because, we are told, the investigation is delicate and difficult. But some ten days ago I ascertained from private sources that the bacillus of cholera had been found in these dejections; only I was further informed that such germs were always found in cases of cholera nostras. To distinguish them from the true Asiatic cholera germ it was necessary to cultivate the germ and produce successive generations. This has been done, and as nothing is published on the subject it may be concluded that probably the result is not encouraging. Indeed, rumours are already circulating that new theories will soon be afloat as to the etiology of cholera which may tend to show that there is not so much difference as is generally supposed between cholera nostras and true cholera.

The epidemic commenced last April at the prison and asylum of Nanterre, which was originally built to hold 2000 inmates. In practice it has become not merely a prison but a sort of asylum for vagabonds and has contained sometimes as many as 5000 persons; consequently there have been all the evils of

overcrowding. Precautions were taken to supply the inmates with pure water. A very deep well was dug into the chalk and was surrounded with steel tubing, so that no surface water could reach and contaminate the well. Some Seine water, however, is also provided at the prison where it is used for working hydraulic lifts. By some mistake or mismanagement the Seine water, instead of the well water, had been distributed for drinking purposes. The epidemic among the prisoners thereupon broke out, with the result, according to M. Monod, who is the Director of the Public Hygiene Department of the Ministry of the Interior, that some fifty cases of a suspicious description ensued causing forty deaths. From the prison the epidemic spread to the neighbouring suburbs, and soon there were twenty-five deaths to deplore among inhabitants living near the Nanterre prison. The well water provided at the prison contained only 0.0015 gr. of organic matter and the Seine water 0.0018 gr., but Dr. Miquel found in the latter 37,000 bacteria to the cubic centimetre.

The epidemic has spread much further afield, but it still seems connected with the drinking of Seine water. Thus at Argenteuil seventeen cases occurred at the commencement of June, when the water of the Seine was substituted for the water of the Oise. The Consultative Committee of Hygiene of France has passed a resolution demanding that the water companies should not be allowed to deliver Seine water to their subscribers without giving them due warning. This is actually done, but perhaps not efficaciously. The position of the Paris water-supply is as follows. In ordinary times 135,000 cubic metres of water are consumed in the day; but when the temperature rises to about 70° F. there is an increased consumption of water equal to about 30,000 to 40,000 cubic metres more. The water works are then obliged to make up the difference by giving Seine water. Nor is it practical to purify efficaciously so great a volume of water. No sterilising apparatus could deal with such a quantity. Moreover, it is not possible to ration the supply, for while the supply was stopped the pipes would get filled with air, and this is attended with many inconveniences and dangers; and, on the other hand, there would be no water to flush the closets. The best hope of the Parisians rests on the fact that 87 kilometres out of the 102 kilometres of the aqueduct, which will bring the water of the Vigne to Paris, are now constructed. Perhaps this additional supply of pure water will be available next summer; in the meanwhile, the inhabitants are asked to carefully boil their water and to wait patiently. As a temporary measure it has been decided to apply the Pasteur filter to the Wallace drinking fountains, so that prudent persons may go to these fountains and fetch their supply of drinking water. But the number of prudent and thoughtful persons is very limited, so the epidemic continues. Also the waters of the Vigne will only reinforce the Paris supply; the suburbs, where the epidemic most generally prevails, will continue to drink the Seine water. M. Sellier, for instance, who is mayor of Colombes, writes to complain that the treaty with the water company supplying his district is binding for another thirty-five years. There is no clause in the treaty giving the concession for the water-supply which enforces the filtration of the water. These treaties are already some twenty-five years old, and twenty-five years ago the dangers of an impure water-supply were not understood as they are in these modern days of bacteriological science. The districts of Bois-de-Colombes, of Asnières, Courbevoie, Puteaux, Nanterre, Suresnes, Gennevilliers are all in the same predicament. What will be done under these circumstances no one can yet foresee. The companies are legally entitled to supply water which is said to be dangerous to drink for another thirty-five years.

Since writing the above I have been informed on the best authority that the publication of the official report on the epidemic has been suppressed by order of the Prefect of the Seine. This report was drawn up by Dr. Proust, who was one of the representatives of the French Government at the Venice Sanitary Conference. The Consultative Council of Hygiene met at the Ministry of the Interior and heard and adopted this report. It was printed, Dr. Proust corrected the proofs, and it was about to appear in the columns of the *Official Journal* when M. Pourbelle, the Prefect of the Seine, interfered and prevented its publication. He feared that the report would create a disastrous panic. What his arguments may have been can be gathered from the incident which occurred a few days ago at a meeting of the County Council (*Conseil Général*) of the Department of the Seine. M. Vaillant attempted to speak about the epidemic, but was

most violently interrupted by the councillors who represented some of the districts affected. Finally, M. Pourbelle rose and exclaimed that he could not understand the fanaticism of sanitary reformers which led them to make speeches that would tend to reduce the value of house rent in the suburbs of Paris. Then, to counteract the influence of the few words that M. Vaillant had been able to utter, the Prefect of the Seine declared that there was only one commune contaminated. Many leading sanitary reformers are indignant at the attitude adopted by the Prefect of the Seine. It is a good illustration of the difficulties in the way of sanitary reformers. Besides, anyone who has studied the death-rate knows full well that it is not in only one commune, but in twenty-four communes or districts, that cases of a suspicious and dangerous character have occurred. Many of these communes are agreeable semi-rural districts outside Paris, where Parisians who cannot altogether absent themselves from town take lodgings during the summer months. If M. Pourbelle had his own way people would be allowed to leave Paris, where, as a rule, pure spring water is obtainable, so as to dwell in suburban districts where nothing but Seine water is available, and this just at a moment when it seems very evident the Seine water is more contaminated than usual. Paris is wealthy enough and has sufficient resources within itself to bear the loss of a few visitors who might be scared away by the publication of Dr. Proust's report; while its leading position as the first town in France imposes upon it the duty of setting a good example. The evil should be met openly, face to face; everyone should know the truth and then it should be possible to take the proper precautions. Secrecy would be bad policy were it possible, but in Paris it is impossible. The Prefect of the Seine cannot, for instance, prevent the papers relating that Madame Vitté, the wife of a porter of a manure factory in the Rue de la Haie Coq died suddenly on July 3rd after only a few hours' illness; that on the same day, and also at Aubervilliers, Alfred Duval died suddenly and that there were other cases of a suspicious description at the Quatre Chemins; that at Courneuve Madame Chevalier and M. Boulogne, both living in the Rue d'Aubervilliers, died in the same manner; that at St. Denis, at the Avenue de la Plaine, there were other cases within the last day or two. Finally, yesterday, within Paris itself, in the Rue Oberkampf, a case is recorded. A special meeting of the municipal council of Clichy has been held to deal with the question. There is no disguising the existence of the epidemic, the great extent of the area it covers and the suddenness of the deaths it occasions. By suppressing the report of the Consultative Council of Hygiene more mischief and a greater panic will result than could ever have ensued from its publication. There is no attempt made in London to conceal the gravity of the present scarlet fever epidemic; and Paris shows itself behind the ago in resorting to the feeble stratagem of secrecy. I do not believe that any prominent French medical man or sanitary reformer approves of this ostrich-like policy.

Paris, July 6th.

## SOCIETY FOR THE STUDY OF INEBRIETY.

### "Cures" for Inebriety.

THE quarterly meeting of the Society for the Study of Inebriety was held on Tuesday afternoon at the rooms of the British Medical Society, 11, Chandos-street, Cavendish-square, W. Dr. Norman Kerr presided.

THE PRESIDENT said that hitherto temperance reformers in this country had usually worked by straightforward and intelligent methods and had exercised that most valuable quality in reformers and everybody else—patience; and, as the magnificent results of the great temperance movement showed, a very large number of drunkards had been rescued, reformed or cured. But human nature was very impatient, and in these latter days there had arisen a feeling amongst a great many people that the evil of intemperance was growing so rapidly and extending so widely, and that the consequences in the present day and to posterity were so tremendous, that they must find some short cut to temperance, some miraculous method of speedily reaching the goal which neither they nor anybody else understood. Mesmerism and hypnotism were straightforward and open remedies for drunkenness and if applied in the presence of medical men and witnesses they could not be called secret remedies. He wished, however,

specially to refer—as circumstances had arisen to render this very necessary—to a so-called secret “cure” which was named the “double chloride of gold cure” to which allusion had already been made in THE LANCET and other medical journals, and to advocate the merits of which a meeting was convened to be held under the auspices of the Church of England Temperance Society, presided over by Bishop Barry; but, owing to his (Dr. Kerr’s) representations to the Bishop of London and Bishop Barry, that meeting had been adjourned *sine die*. The real but unavowed object of that meeting was to float a syndicate to raise £150,000 in this country in order to purchase the right of using this so-called “cure” in England; £110,000 of this—according to the circular he had sent—was to be given in cash and £40,000 in shares to the vendors. There was to be a commercial company for pushing the golden remedy similar to other companies with which they were familiar. They were told in a pamphlet that “without any effort on the patient’s part” a cure would be effected by the use of this wonderful and infallible remedy as “certainly as night followed day.” Already the decoction had apparently proved, if not a golden remedy, at least a veritable gold mine, for the bottles which contained it (one of which the chairman produced) were sold in pairs and each pair cost 9dols., or 36s. There were twenty-six branches in America for the sale of this “cure.” If the remedy were really a remedy for the victims of intemperance, surely it would have the support of the leading temperance reformers in America; but this, Dr. Kerr showed, was not the case. One writer in the *North American Review*, who had lauded this so-called cure, which he had tried, died in New York, a few months after the appearance of his article, the death of a pauper drunkard. The fact was that this falsely called “remedy” was very dangerous, and was compounded of a number of poisonous intoxicants. They would hear from Dr. Usher of Melbourne, who had been to Dwight, Illinois—the centre of the manufacture of the “cure”—what he thought of it and its effects. Dr. Usher, the chairman incidentally mentioned, was about to publish a new book on “Alcohol and its Treatment.” A distinguished analyst, a member of a great medical corporation in England—whose name the chairman was not at liberty to mention—had made a careful analysis of the so-called “bichloride gold cure.” The dictum of this gentleman on a subject of this kind would, were he (Dr. Kerr) at liberty to name him, be received by all competent authorities without any hesitation whatever. Well, he (the analyst) found neither gold nor chlorides, but what he did find present was: water, 61·31 per cent.; sugar, 6 per cent.; a small quantity of mineral salts, principally lime, probably from herbs; and 27·55 per cent. of pure alcohol as intoxicating as port or sherry and more intoxicating than champagne and claret. And yet old teetotalers, unconscious of the composition of the “gold cure,” had been actually recommending a so-called “remedy” more intoxicating than champagne or claret. Not only was this compound preparation condemned by the whole medical press of America and Britain, but by the whole reputable and respectable medical profession of the United States. Having spent many years in America he could bear this testimony to the fact that although there was not there as here a system of registration, yet there were as honourable members of the medical profession in America as in Britain. The testimony of Dr. C. H. MERR in an American journal as to the “results” of Dr. Keeley’s treatment showed that Colonel Mines a few weeks after his “cure” died of alcoholism; Senator Fair’s son died of heart disease directly attributed to the treatment; Walter R. Earle died a raving maniac a week after his dismissal; Henry Anstey died during treatment; Dr. Miller of Illinois, Luther Benson and Charles Vaughan became insane; ex-Congressman Hopkins also went mad and died soon after treatment. This so-called “remedy” was opposed to the whole true principle of enduring temperance reformation. The first thing to do with the drunkard was to cut off the poison, to stop the supply at once. Teetotalism was essential to the effectual cure of the drunkard. What, after all, was inebriety? It was a complex disease and needed moral, mental and physical treatment. An inebriate to be cured must himself have a desire to be cured, and must exercise a certain amount of will power when the narcotic action of the drugs had been swept away from the brain by the exclusion and prohibition of alcohol, then the little will power left would reassert itself.

Dr. J. E. USHER of Melbourne, Australia, then described a visit he had made to Dr. Keeley’s sanatorium at Dwight. He

was, he said, the first British physician who had visited Dr. Keeley’s place. Three leading physicians from Boston, New York and Philadelphia respectively—representing different societies—had preceded him, remained half a day or a few hours and then returned home. Six weeks later all their friends received circulars intimating that these gentlemen had been remarkable successes in the cure way. Although he had visited the place with credentials from the Government, the Cabinet and lay press of Australia, he had been traduced since he left Dwight. Dr. Keeley (who seemed very uneasy while he conversed with him) told him he had used the “remedy” twelve years and it was very successful. He asked him what was the *rationale* of his treatment; what prescriptions he used. Dr. Keeley replied: “We will not go into that. I know it is all right. If you want to know anything about it, the secretary or chemist will tell you.” The “chemist” turned out to be a sort of page-boy to Dr. Keeley. He (Dr. Usher) was introduced to Dr. Blaine, the “chief of the staff.” The staff consisted of unsuccessful practitioners, who were paid from 3000 dols. to 7000 dols. a year, and they did all the work. Dr. Blaine took him where three rows of men were being injected in the left arm with five drops out of a little porcelain bowl containing a pinkish material—atropine really. Four of the patients wore glasses, and they told him that they could not see three or four days after the treatment, and became blind weeks together. Seventy per cent. of the patients had glasses. They suffered too from giddiness. One patient had been at the institution nine weeks, he said, and was afraid to leave because three of his “pals” who had left ten days before got drunk and had to come back. Another patient remained because he said if he stayed there two or three months an aunt had promised him an annuity, and he “wanted to see the time out.” There was a “Bichloride of Gold Club” in which there were “graduates” and “undergraduates,” so called. They did not appear to be healthy; some of them seemed to be under the influence of an opium drug—atropine. About £40,000 a year was spent in advertising or in subsidising people to advertise the concern, which was now engineered by some of the “smartest” men in America. The thing was most lucrative. Two bottles of the preparation cost 36s. Every man who went to Dwight had to pay 25 dols. down and from 5 dols. to 25 dols. a week; and all this money flowed into the coffers of the company.

The PRESIDENT said he had invited Dr. Keeley to attend that meeting, but he replied that he had that evening to deliver a lecture at St. James’s Hall on “Drunkenness and its Cure,” adding that he would be happy should any members of that Society desire to hear his address to forward tickets.

Dr. MORTON (Kilburn) moved: “That this meeting of the Society for the Study of Inebriety (of which the members are registered British medical practitioners) is of opinion that any so-called ‘cures’ for inebriety the composition of which is not disclosed are unfit to be commended by honourable members of the medical profession, who are bound to place the full details of their treatment before their professional colleagues, a requirement as essential in the interest of the public as it is consonant with the disinterested practice of scientific therapeutics.”

Mr. J. SMITH, late superintendent of the Dalrymple Home, seconded the motion, which was carried unanimously.

Surgeon-Major PRINGLE moved, and Mr. Jabez Hogg seconded: “That this meeting, having been informed by a competent London analyst, who has made a special analysis, that the alleged ‘bichloride of gold cure’ shows no trace of gold or of chlorides and contains 27·55 per cent. of alcohol, condemns unreservedly the prescription of such an intoxicating preparation to an inebriate.”

This too was carried unanimously.

Dr. F. R. LEES moved a vote of thanks to Dr. KERR and thanked that gentleman for the prompt and effectual part he had taken in the exposure of this so-called “cure” of inebriety.

Mr. J. HILTON (United Kingdom Alliance) seconded the motion, which was carried *nem. con.*, and the meeting then terminated.

THE baths of University College Hospital are open between the hours of 2 and 5 p.m. and of 6 and 8 p.m. to patients under the advice of their medical practitioners. Wednesdays will be set apart for female and Thursdays for male patients.

## DUBLIN UNIVERSITY TRICENTENARY.

THE week has been a gala one in Dublin and garden parties, concerts, balls and receptions have filled up every available period. The first stone of the historic edifice of Trinity College was laid in 1591, in Queen Elizabeth's reign. Early in 1593 the institution was opened for the reception of students and the first conferring of degrees took place in 1600. The mayor and citizens granted the site of the Abbey of Allhallows and twenty-eight acres of derelict land, which latter now brings in an annual income of several thousand pounds. Her Majesty Queen Elizabeth gave some Crown rents and a yearly grant of £400 from the Concordatum Fund, which latter ceased in the present century, and the former is worth about £5 yearly. Lord Burleigh was appointed first Chancellor and Archbishop Adam Loftus the first Provost.

The proceedings of the tricentenary celebration commenced on Tuesday, the 5th inst., at the Examination Hall by a reception by the Provost, who welcomed the various guests and delegates. At 11 A.M. a procession was formed in front of the library and museum buildings. A military band led, followed by the students in gowns and caps, then the guests and delegates, including representatives of universities in their robes and of scientific societies. Next the foreign guests and delegates, followed by representatives from Cambridge and Oxford Universities; then three members of the Dublin Corporation, graduates and honorary graduates of the University, professors, junior and senior Fellows, another band terminating the procession. As the guests and delegates passed out of the College gates they were presented with buttonhole bouquets by young girls dressed in fancy costume. The procession passed through various streets, walking four abreast until they reached St. Patrick's Cathedral, where a commemoration service was to be held. A procession of the kind was never seen before in Dublin and attracted immense crowds. The bright colours of the graduates' gowns and the quaint costume of the foreign guests with robes of yellow, orange, fawn, crimson and other shades presented an imposing appearance, and the headgear of some of the guests was of the strangest character. Some of the continental guests were in full evening dress with crosses and orders but without robes, while others wore gowns over military uniforms. One stalwart German, a Heidelberg student, walking with drawn sword, created considerable interest, and many surmises were expressed as to what he represented. Some thought that because he wore high boots and a velvet cap with an immense ostrich feather he belonged to the Order of Foresters. An old gentleman in an immense ruff reminded us of the mediæval period. When the procession had reached the Cathedral and had taken their places the scene was magnificent and unique. The State pew was occupied by the Lord Lieutenant, who wore the collar and star of the Order of St. Patrick. There were eight bishops present, the Archbishop of Dublin and the Lord Primate. The choir moved in procession up the centre aisle to the chancel singing the hymn "All People that on Earth do Dwelt," and the choir and clergy being seated the hymn "O God our Help in Ages Past" was sung. The Archbishop of Dublin read the lesson and the Dean of St. Patrick's preached, the anthem being Blow's "I Beheld and Lo."

At three o'clock the cricket match, Dublin University v. Cambridge University, attracted a good many to the College Park, where a three days' match was being held; and at four o'clock there was a garden party in the Fellows' Garden, Trinity College, where about 2000 people enjoyed themselves for upwards of two hours, among the notabilities being his Excellency the Lord-Lieutenant, Viscount Wolsley, Lord Rosse, Chancellor of the University, Earl Dufferin, Chancellor of the Royal University, &c. To inaugurate the occasion a mulberry tree was planted by Miss Salmon, the Provost's daughter, a sapphic ode by Professor Tyrrell being sung of which the following is a translation:—

"Thee did a kindly hand long stilled in death  
Plant here to reach an old age green and hale,  
Years full three hundred now have passed, but thou  
Survivest all their tale.

"To thwart Death's envy of thy long-lived race  
A maiden doth a youthful sister give,  
Bidding her with thy dusky leaves to twine  
Her kindred leaves and live.

"Mayest thou, new Tree, in dark-green mantle clad,  
No less accomplished scions here survey  
From age to age than those thy sister saw  
Crowned with renown for aye."

In the evening the Fellows' professors, and students entertained at dinner several distinguished graduates, including Mr. Alma Tadema, Professor Sayce, Professor Waldeyer, Professor Hashagen, Professor Gusscrow, Sir G. Humphry. On behalf of the guests, Professor Schiffer of Vienna, Professor Knapp, Professor Oort of Leyden and Professor Cremona of Rome responded for the Universities.

At 9 P.M. there was a performance by the University Choral Society in the Leinster Hall of the Tricentenary Ode, composed by Sir Robert Stewart and written by Mr. G. F. Savage Armstrong. The ode was in every way worthy of the high reputation of the author and composer. The evening concluded by a reception at the Mansion House.

On Wednesday the 6th inst. the conferring of honorary degrees took place in the Examination Hall, Trinity College. All the recipients of the degrees were present, with only one exception. The proceedings were presided over by the University caput, consisting of the Earl of Rosse, chancellor; Rev. Dr. Salmon, provost; and Rev. J. Barlow, senior master, *non Regent*. Sir Robert Stewart performed a selection of music on the organ before the proceedings commenced. At 12 o'clock the procession of those who were to receive the honorary degrees and the College dignitaries entered the hall, the members of the caput being preceded by the College steward carrying the mace. At 3 P.M. there was a meeting in connexion with the graduates' memorial and at the same hour the cricket match between the Dublin and Cambridge Universities entered on its second day. At 3 P.M. there was a garden party at the Viceregal Lodge, in the Phoenix Park, the attendance being large and fashionable, while in the evening the tricentenary banquet was held in the Leinster Hall.

We must reserve an account of Thursday's and Friday's doings until next week.

## ACTINOMYCOSIS.

AMONG the diseases of animals one of the most interesting is that due to the presence of the ray-fungus and consequently known as "Actinomyces"; and as it is also a malady of mankind—though much less frequently observed—its interest is much enhanced, especially as it is in the majority of cases an incurable disorder. Its existence in the human species and also in animals may be more common than is usually supposed; for the presence of the fungus may be overlooked and the pathological changes it sets up may be ascribed to something else. Though for very many years the morbid conditions due to its action were recognised in animals, and chiefly in cattle, yet the discovery of the microphyte is only of recent occurrence and the numerous and diverse names given to these conditions are now merged into that which signifies their true nature. So far as animals are concerned, actinomyces is a widespread and somewhat multiform disorder. It prevails throughout Europe and is common on the American continent and in Australasia. But in Europe its prevalence is singularly diversified; for while in some countries it is frequently seen—as in Bavaria, Saxony, Lombardy, Holland, Denmark and England,—in others—as France—it is comparatively rare. Even in this country its localisation appears to be strikingly partial; for while in Scotland and Ireland it appears to be exceedingly infrequent, in England it is not at all so, and in some parts—as Lincolnshire—it is of very common occurrence among cattle. It is equally curious to note that the form actinomyces assumes is almost special in certain countries. In Germany, for instance, though actinomyces of the pharynx is frequently observed and appears as pharyngeal polyp, lymphomata and lymphosarcomata—soft tumours containing myriads of actinomyces nodules, and which interfere with deglutition and sometimes obstruct the respiration—yet according to reports actinomyces glositis (the *Holzsaenge* or wooden tongue) is the most common form it assumes. It is the same in Holland and Italy; and though in these countries and Germany the bones of the jaws are sometimes the seat of actinomyces tumours (the so-called "osteosarcoma" and "spina ventosa"), yet they are not nearly so often seen as in this country, the United States of America, or Australia; while in France, where actinomyces appears to be almost non-existent, the glositis form has been scarcely recognised, that of the jaws being almost the only one observed. In England the three forms are witnessed, but perhaps the pharyngeal region is that which is most frequently invaded, though the first instance

on record, that reported by Fleming, was one of actinomycotic glossitis. Of course, the disease may affect any organ or tissue and though the jaws, tongue and pharyngeal region are by far the most frequently involved, yet pulmonary and mammary actinomycosis are far from infrequent, and the microphyte has also been found in tumours on the skin and elsewhere, as in the omentum, kidneys, muscles, liver, spermatic cord, vertebrae, &c. The tumours vary considerably in size, being from that of a pea or hazel nut to the volume of the fist or a child's head, and they are irregular or nodulated on their surface; while in section they are rather light-coloured and granular, the granules being of a faint yellowish tint. Each tumour is in reality a kind of fibro-sarcoma studded and interspersed with tuberculiform nodules which are developed around tufts or masses of actinomycetes in different stages of development or regression. As has been remarked, each of these nodules exactly represents, histologically, a Köster follicle—that is, the central portion is more or less caseous and consists of multi-nucleated giant cells, voluminous epithelioid cells, with clusters of actinomycetes, some small groups of these being often made out in the interior of the giant cells; the whole being enclosed in a more or less thick layer or envelope of concentrically arranged fusiform cells, the periphery of which becomes gradually combined with the proper tissue of the tumour. After a certain but variable period these nodules become calcified, and the fungus cannot then be so readily distinguished without recourse to special treatment; but in discharges the minute yellow granules or nodules containing it can always be easily detected by placing a thin layer of the matter on a piece of glass or thin layer of cotton wool and holding it up to the light. With regard to the prevalence of actinomycosis in cattle in different countries, it is impossible to obtain reliable information. If rumour can be accepted, the United States of America has the largest proportion, and it has been imagined that about 5 per cent. of the bovines in England, Germany and Italy are its victims. In France only 95 cases have been noted among 130,000 animals, being 0.72 per 100, or one diseased ox in 1400; and it is seen chiefly in the Mancheau and Normandy cattle, those of Brittany and Limousin being almost exempt, as they show only 1 in 10,000. It is to be remarked, however, that these figures only refer to living animals which exhibit the disease externally. Besides the bovine species, the pig is the only other domesticated animal frequently attacked, and it is somewhat curious that the ovine species appears to be endowed with almost complete immunity. Herbivorous and omnivorous animals—such as the ox, sheep, pig and man—have furnished most instances of it, the carnivora being apparently refractory, though one case is recorded as occurring in the dog. The mode in which infection takes place is not yet thoroughly established, but there can scarcely remain any doubt that it is effected by the introduction of the fungus or its sporules through a wounded or abraded surface; in the great majority of instances, in which the head is involved, the actinomycetes are introduced with the food, and possibly by means of grain, straw, or other kind of herbaceous aliment, and in the form in which the tongue is affected, and in which it runs its course most rapidly, the cases are those of animals grazing about harvest time. Pianna records a case of lingual actinomycosis, in which the lesion was manifestly due to the penetration of a barley-seed barbule into a fistulous wound, as the barbule was covered with the actinomycetes when he examined it; and Jöhne has found numerous fungi on fragments of straw fixed between the pillars of the soft palate in a pig; while at a recent meeting of the Medical Society of Greifswald, Professor Grawitz exhibited the inferior maxilla of a calf that had succumbed to actinomycosis, the fungous masses and bone of which when sawn through were discovered to contain several grains of corn, it being surmised that the actinomycetes had obtained admission to the tissues through the abrasions made by these grains. This mode of penetration will explain the frequency with which the jaws, mouth and pharynx are involved; wounded gums or carious teeth afford a good lodgment for the parasite. In Italy and Bavaria as well as in Pomerania the actinomycotic glossitis has prevailed in an almost epizootic form during outbreaks of foot-and-mouth disease. Inhalation of dust from dry fodder will account for the pulmonary form, and the invasion of other organs may be accounted for in a similar manner. The fungus is in all probability conveyed through the connective-tissue spaces, the blood stream and lymphatics having little or no share in its distribution in the body.

There is no proof that the malady is contagious in the

ordinary acceptation of the term, and if it is at all so it must be in a very feeble degree. The infection of mankind appears to be quite independent of diseased animals, as it exceedingly rarely happens that persons suffering from actinomycosis have had any relations with diseased cattle. Moosbrugger has collected the histories of seventy-five cases, and of all these only one of the persons had been in contact with cattle suffering from the maxillary form, while forty-nine of them had nothing at all to do with cattle. The malady is difficult to produce experimentally, as although it may be successfully developed now and again, yet when a series of inoculations are attempted the result is always failure; so the conclusion arrived at is that the source of infection is the same for mankind as it is for animals, and that the medium of conveyance in both is probably grain of various kinds; as in the majority of cases of human actinomycosis the origin of which has been traced, it has been found that the persons had chewed or unwittingly swallowed a piece of straw, or barley or wheat grains with the hull on. There does not seem to be any reason whatever to interdict the flesh of affected animals as food for man so long as the actually diseased parts are destroyed.

The treatment of actinomycosis is a matter of great importance, of course, and it has generally been considered, in man at least, an almost incurable, if not a hopeless disease. But Raffer, in the *Reforma Medica* of February 4th, has reported four cases of recovery, in which the disease was accessible to surgical measures. These were scraping and the injection of antiseptics into the tumours—these injections consisting of a 5 per cent. solution of carbolic acid in glycerine, and if sinuses were present, cotton wool saturated with this fluid was introduced into them. Veterinary surgeons have for a long time employed tincture of iodine with much success as a local application, but quite recently a very distinguished teacher at the Utrecht Veterinary School has drawn attention to the value of iodide of potassium in every form of the disease when given as a drug; from his experience of this agent in cattle affected with actinomycosis, he pronounces it an infallible remedy and Professor Nocard, at a recent meeting of the Paris Central Veterinary Society, in giving an interesting account of the disease, mentioned instances to prove that this medicament promptly and radically cures actinomycotic glossitis in cases which were formerly deemed hopeless. The dose for the ox began with 6 grammes in half a pint of water once a day to commence with, soon increased to 8 grammes, until signs of iodism began to manifest themselves, when it was continued for a few days longer; amendment gradually ensuing without any local treatment. In some instances 6 grammes were given daily for eight days, and when marked amelioration in the symptoms was noted—which was generally in about eight days—the dose was reduced to 4 or 5 grammes at the most. If iodide of potassium is of such potency in this disease as it affects cattle, why should it not be as useful in man? It is certainly worthy of an extensive trial in the human species in which treatment is so often unavailing, especially in those cases where the affected structures cannot be reached. Should the iodism be rather severe there is no great danger to be apprehended, as with the diminution of the dose of the drug or its cessation the more serious symptoms soon subside. It is to be hoped that in medical practice it will prove itself to be as much a specific for this intractable and grave disorder as it is reputed to be in veterinary practice.

## MEDICAL PRACTITIONERS AND THE GENERAL ELECTION.

In illustration of the fact that medical men are becoming alive to the necessities of bringing their particular case before the notice of the candidates for Parliamentary honours we note that a deputation of medical men waited upon Mr. Byron Reed, a candidate for the Eastern Division of Bradford, to ascertain his views on matters affecting the profession in its relation with the public. The importance of the facts is not restricted to one constituency and we therefore trust the attention of all candidates may be directed to the facts which were urged by this deputation.

Dr. Hime, in addressing Mr. Byron Reed, alluded to the progress of unreasonable legislation which singled out the medical profession for the compulsory performance of certain duties

which the Legislature had come to regard as of great public utility. Now the medical profession objected strongly to the knowledge which they had gained without the assistance of the Government in their medical studies being claimed by the public as their property under any circumstances and whether they were paid for it or not. At the present time a medical man was under legal compulsion to sign a certificate of death for which he received no remuneration whatever. By law the certificate could only be utilised for the purpose of burial, but in practice it was utilised for insurance, for club purposes and many others. The notification of infectious diseases had also been made compulsory on medical men, a thing which was without analogy in other cases. He drew attention to the enormous number of deaths which were not inquired into although they were not certified by any medical man. It was left absolutely optional with the registrar whether he would accept the tale of any informant as to the circumstances of a death and certify for burial or not. Throughout the whole country medical men found it not infrequently happened that if knowing of the circumstances of a death they thought it necessary to refuse a certificate because they considered there had been foul play, yet, when they notified that fact which was the result of their personal knowledge, the coroner might and did constantly grant certificates of burial. In order to justify him in doing so, as a rule, he sent his policeman to make inquiries. He, of course, only received the information from interested parties, and that was one-sided, and supported his (Dr. Hime's) statements.

Other subjects calling for reform were instanced, including the question of medical and post-mortem examinations in medico-legal cases. The inadequacy and injustice of the present method, by which any practitioner, who may be practically the mainstay of the prosecution, can alone and unaided and without any supervision make a post mortem, on the report of which a life may be dependent, were strongly condemned.

Mr. Byron Reed, in reply, expressed his astonishment at the number of facts brought to his knowledge for the first time. They were such as called for the serious consideration of the Legislature, and he promised, if returned to Parliament that any bill bearing upon the medical profession or its relation to the public, either directly or indirectly, should not be carried without receiving his most serious attention, and he would, as far as in him lay, urge this upon those members of the House with whom he had any personal influence.

The deputation thanked Mr. Byron Reed for the interest he took in the matter and the courtesy with which he had received them and retired.

## THE LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY, LIMITED.

A WELL-ATTENDED meeting was held on Monday, June 20th, 1892, at Dr. Arthur Roper's house at Lewisham Hill, for the purpose of establishing a division of the above society for the Lewisham, Woolwich, Greenwich, and adjacent parts of the S.E. district. On the motion of Dr. Purvis, seconded by Dr. Stevenson, Dr. Arthur Roper presided. Dr. Roper briefly stated his opinion as to the necessity and utility of such a society for London and the neighbourhood and called upon Dr. Mead to more fully explain the matter. Dr. Mead then went into the details connected with the formation of the Society and the steps which had been taken to place it on a broad and representative basis, and to secure to each member the fullest possible consideration of his case, either locally, or if he deemed it advisable, by the Central Council and the Emergency Committee, both of which were easily accessible. The Legal Council, consisting as it did of men of very high standing, constituted a court of final appeal of the very highest character and value. As to funds, the Council had ample means at their disposal, and were prepared at once to defend any member whose case was worthy of defence. Dr. J. Maxwell, Dr. Mercier and Dr. Purvis spoke in favour of a Society having its central Council in London, and pointed out that by means of the district Councils local cases could be undertaken and probably amicably settled. Dr. Heron pointed out that there was ample room for such a society. This was shown by the large numbers who had already joined this Society. The wish of the Council

was to work amicably with any society seeking to benefit the profession. London was pre-eminently the place where any important case affecting the profession should be tried and the difficulties of general practice could always find better and quicker solutions there, seeing that the majority of the leaders of the profession resided in London.

It was then resolved that a division should be formed for that portion of the south-east district and parts adjacent to it. Dr. Arthur Roper was elected president, and Dr. Scott was appointed secretary to the branch. In addition to those who had already joined, seventeen new members gave in their names.

## MILITARY SURGERY IN CHILI.

A REPORT has been published of the work done in the San Augustin Hospital, Valparaiso, from Aug. 28th, 1891—when the Constitutional party gained possession of the city after Balmaceda's defeat—to Jan. 15th, 1892, when the hospital was closed. It will be remembered that the fighting had been discontinued four or five days previously, the great battle having taken place from the 21st to the 23rd. When Señor Benjamin Edwards took charge of the hospital as administrator on Aug. 28th the building was empty and he had to make the best arrangements he could in the disorganised state of the town for the reception and care of the wounded who were being brought in from the field of battle. The medical service had to be organised. Dr. José Rivero was appointed chief medical officer and a staff of surgeons and dressers was soon got together, a good deal of assistance being obtained from the surgeons of the English, French, German and United States vessels at anchor in the harbour.

During the period the hospital was open 1008 patients were treated, not reckoning those who were passed on to other hospitals on ambulances within the first week or two. Of this number 936 were discharged cured or improved and seventy-two died. In 132 cases there were two or more wounds, and in five there were four bullet wounds. The rifle used seems to have been the Mannlicher, which has a small, highly polished, steel-tipped projectile with a very high velocity and a gyratory motion. The wounds were as a rule small and not dangerous to life, though sufficiently serious to put a man *hors de combat* for several weeks. The orifices of entrance and exit were very small and generally cicatrised quickly, with very little suppuration. When the path was merely through muscular tissue healing generally took place without any trouble, just as in a subcutaneous wound—that is, if care had been taken to remove all foreign bodies. The orifice of entrance had clean edges and a diameter much smaller than that of the ball. The orifice of exit was very different and was of various shapes, according to the bony or tendinous tissues the ball had met with. Owing to the outer casing with which the bullet is furnished it generally preserves its form and so produces far less injury to the tissues than the leaden bullets used in the Franco-German war, which frequently broke or became splayed out when they struck a bone. Extraction is too, of course, a much easier matter than with the old-fashioned bullets. In many cases where considerable osseous lesions were produced the wounds healed well and rapidly.

There were twenty-four cases of hospital gangrene attributable to the impossibility of maintaining rigorous aseptic conditions, and doubtless accelerated and aggravated by the drinking habits of the patients. The wounds of the upper extremity are returned as 23 per cent. of the total wounds; those of the lower extremity being 42 per cent. The mortality of fractures of the femur was 25 per cent. The head of the femur was removed five times, with three deaths. The mortality of wounds of the thorax was 54.5 per cent., which compares favourably with that of the Franco-German war, which was over 60 per cent., or that of our troops in the Crimea, which was nearly 70 per cent. There were ten cases of wounds of the abdominal walls, all of which recovered, and sixteen penetrating wounds, of which six recovered, thus giving a mortality for all abdominal wounds of 62.5 per cent., as against 87 per cent. in the Franco-German war and 92 per cent. in the English army in the Crimea. The mortality of the cases of fracture was 6.96 per cent., the number of operations 46.03, and the number of cases where conservative surgery was successful was 47.01 per cent.

METROPOLITAN HOSPITAL SUNDAY FUND.

THE following list is a continuation of the contributions received at the Mansion House up to Thursday last in aid of the Metropolitan Hospital Sunday Fund:—

	£	s.	d.
St. Peter's, Vero-street (Rev. W. Page Roberts) .. ..	823	3	7

N.B.—The congregational collections are mostly an improvement on last year, but the gross receipts must be less for 1892 unless donations are sent to the Lord Mayor to form some equivalent to the £5000 sent in 1891 by the late Duke of Cleveland.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

*Lewes Urban District.*—Mr. J. G. Braden has a fairly favourable report to give for last year. The death-rate was 15.1 per 1000 living; but the decennial average is 17.6, and this is very properly regarded as too high for a town like Lewes. The drainage of Lewes is receiving and calls for attention. But the progress made is slow and in the Cliffe portion of the district, which lies low, there are indications that amendments are needed. The town water is good and arrangements are being made to ensure its being abundant. The hospital was not used last year, although a number of scarlet fever attacks occurred. In only two instances did multiple cases arise and it is implied that the attacks did not occur under circumstances actually calling for removal to hospital. In short, the Lewes hospital seems to serve rather for emergencies than for any sustained isolation of infectious cases.

*Coventry Urban District.*—Coventry is an old city and has sanitary difficulties to contend with, but during the last five decennial periods the general rate of mortality has gone down from 27 to 18.5 per 1000. Last year it stood at 19.6. House property and its defects constitute a substantial hindrance to sanitary progress, and Dr. Mark Fenton urges prominently the need for the adoption of more efficient measures for the improvement of the dwellings of the poor. An increased water-supply and better arrangements for the scavenging of refuse are also needed. The city isolation hospital has all along been satisfactorily worked under Dr. Fenton's supervision. In 1874, when it was first opened, twelve patients were admitted, but since then the annual admissions have reached and even exceeded 200. Every effort is made to prevent the spread of infection by means of isolation, and in this connexion it may be mentioned that whereas the zymotic rate for the ten years ending 1881 was 3.3 per 1000, it was only 1.7 in the decennium terminating last year.

*Worsbrough Urban District.*—The death-rate of this little urban district of less than 10,000 inhabitants reached 23.7 per 1000 last year, the excess being due to measles, scarlet fever, influenza, and whooping-cough, diseases which had not been brought about by defective sanitary circumstances. Unfortunately, little could be done as to removal of scarlet fever cases to the Barnsley hospital. Dr. M. T. Sadler makes certain suggestions as to improvement in scavenging and as to overcrowding. Otherwise sanitary matters seem in a fairly satisfactory state.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6378 births and 3348 deaths were registered during the week ending July 2nd. The annual rate of mortality in these towns, which had been 17.8 and 17.3 per 1000 in the preceding two weeks, further declined last week to 17.1. In London the rate was 16.8 per 1000, while it averaged 17.3 in the thirty-two provincial towns. The lowest rates in these towns were 9.4 in Brighton, 13.6 in Leeds, 13.7 in Blackburn and 13.8 in Hull; the highest rates were 21.8 in Oldham, 21.9 in Manchester, 22.4 in Sunderland and 22.5 in Preston. The 3348 deaths included 486 which were referred to the prin-

principal zymotic diseases, against 514 and 477 in the preceding two weeks; of these, 170 resulted from measles, 108 from diarrhoea, 78 from whooping-cough, 55 from diphtheria, 46 from scarlet fever, 34 from "fever" (principally enteric) and 5 from small-pox. No fatal case of any of these diseases occurred last week in Gateshead; in the other towns they caused the lowest death-rates in Brighton, Bradford and Burnley, and the highest rates in West Ham, Birkenhead, Preston and Sunderland. The greatest mortality from measles occurred in Sheffield, Birkenhead, Birmingham, Leicester, Halifax, West Ham and Sunderland; from scarlet fever in Swansea; from whooping-cough in Sunderland, Croydon, Wolverhampton and Preston; from "fever" Birkenhead; and from diarrhoea in Plymouth, Leicester, Sunderland, Preston and Norwich. The 55 deaths from diphtheria included 38 in London, 3 in Leeds and 2 each in West Ham, Birmingham and Bolton. Four fatal cases of small-pox were registered in London and one in Halifax, but not one in any other of the thirty-three large towns; 35 cases of this disease were under treatment in the Metropolitan Asylum Hospitals and 5 in the Highgate Small-pox Hospital on Saturday last. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2211, against numbers increasing from 1226 to 2066 on the preceding fourteen Saturdays; 331 new cases were admitted during the week, against 213 and 284 in the previous two weeks. The deaths referred to diseases of the respiratory organs in London, which had declined from 304 to 181 in the preceding seven weeks, rose again to 185 last week, but were 27 below the corrected average. The causes of 59, or 1·8 per cent., of the deaths in the thirty-three towns were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Brighton, Portsmouth, Cardiff, Blackburn, Sunderland and in nine other smaller towns; the largest proportions of uncertified deaths were registered in Salford, Oldham, Halifax and Sheffield.

#### HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 17·7 and 19·3 per 1000 in the preceding two weeks, declined again to 18·0 during the week ending July 2nd, but exceeded by 0·9 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 8·6 in Perth and 9·1 in Greenock to 20·3 in Glasgow and 20·8 in Aberdeen. The 502 deaths in these towns included 31 which were referred to measles; 23 to whooping-cough, 9 to scarlet fever, 9 to diarrhoea, 7 to diphtheria, 4 to "fever," and not one to small-pox. In all, 83 deaths resulted from these principal zymotic diseases, against 66 and 85 in the preceding two weeks. These 83 deaths were equal to an annual rate of 3·1 per 1000, which exceeded by 0·6 the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had been 27 and 35 in the preceding two weeks, declined again to 31 last week, of which 27 occurred in Glasgow and 3 in Edinburgh. The deaths referred to whooping-cough, which had been 27 in each of the previous two weeks, fell to 23 last week and included 19 in Glasgow. The 9 fatal cases of scarlet fever showed an increase of 6 upon the number in the preceding week; 5 occurred in Glasgow and 3 in Edinburgh. The deaths from diphtheria, which had been 2 and 8 in the previous two weeks, were 7 last week, of which 5 were recorded in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had declined from 124 to 80 in the preceding three weeks, rose again to 89 last week, but were 17 below the number in the corresponding week of last year. The causes of 57, or more than 11 per cent., of the deaths in these eight towns last week were not certified.

#### HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 31·6 and 27·4 per 1000 in the preceding two weeks, further declined again to 24·6 during the week ending July 2nd. During the thirteen weeks of the quarter ending on Saturday last the death-rate in the city averaged 31·3 per 1000, against 18·9 in London and 17·8 in Edinburgh. The 165 deaths in Dublin during the week under notice showed a decline of 19 from the number in the preceding week and included 20 which were referred to measles, 1 to whooping-cough, 1 to "fever," 1 to diarrhoea and not one

either to small-pox, scarlet fever, or diphtheria. In all, 23 deaths resulted from these principal zymotic diseases, equal to an annual rate of 3·4 per 1000, the zymotic death-rate during the same period being 3·1 in London and 2·2 in Edinburgh. The fatal cases of measles, which had been 27 and 24 in the preceding two weeks, further declined to 20 last week. The deaths referred to whooping-cough, which had been 5 in each of the previous two weeks, declined to one last week. The 165 deaths registered in Dublin last week included 25 of infants under one year of age and 30 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a decline from those recorded in recent weeks. Four inquest cases and 4 deaths from violence were registered; and 60, or more than a third, of the deaths occurred in public institutions. The causes of 16, or more than 9 per cent., of the deaths in the city last week were not certified.

## THE SERVICES.

### CHOLERA AT LAHORE.

THE outbreak of cholera among the medical students at Lahore is said to be of a severe type. Four cases have proved fatal since June 8th, among the victims being a European lady student. A few fatal cases have also occurred among the native patients in the upper wards of the Mayo Hospital.

### GOOD SERVICE PENSION.

It is notified that, on the recommendation of the Government of India, Her Majesty's Government has been pleased to confer a good-service pension on the undermentioned officer from date specified:—In place of Colonel C. S. Maclean, C.B., C.I.E., I.S.C., who succeeded to colonel's allowance on Dec. 14th, 1891, Surgeon-Colonel Archibald Hamilton Hilson, M.D., I.M.S.

### EMPLOYMENT FOR ARMY RESERVISTS.

Medical officers are quite as much interested, of course, as other officers in the well-being of soldiers leaving the Army for the Reserve, and they will be glad to learn therefore that the recent appeal by the War Office to the railway companies promises to be successful. It has been intimated to Mr. Brodrick, Financial Secretary to the War Office, that the companies will be prepared to give about 2000 vacancies annually to Army Reservists of good character. This, taken in connexion with their employment as postmen, which will be hereafter open to soldiers who have served with the colours, is a move in the right direction, and the departments concerned are to be congratulated on having tried successfully to benefit the soldier's position by increasing the opportunities for his employment in civil life.

### SICKNESS IN THE MEDITERRANEAN FLEET.

With regard to the alleged sickness in the Mediterranean fleet it is pertinent to remark that, according to past experience, an increase in the number of fever cases at this season is to be expected. Much of the sickness in the summer is attributable to the heat and local causes, aided by indiscretions of diet on the part of individuals; that which is of a serious character is due to typhoid fever and to another form of fever, the exact nature and causes of which do not seem to have been fully ascertained. Malta and Gibraltar have of late years been healthy, we believe.

### THE WANT OF CIVIL SURGEONS AT INDIAN STATIONS.

We recently called attention to the alleged dearth of doctors in civil stations of Bengal according to the lay papers of that country. Our contemporary, the *Indian Medical Gazette* for last month, alluding to the same subject, says that there is a general impression prevalent that the medical needs of the community at these stations is not sufficiently realised by the Government; localities not remarkable for their healthiness are left with insufficient medical provision.

### EXPERIMENTS WITH SNAKE POISON.

As our readers are aware, the annual loss of life from snake-bite in India is very large. The committee for the management of the Zoological Gardens in Calcutta are constructing a snake-house to contain specimens of all the principal poisonous snakes of the country, in connexion with which it is proposed, as we have already informed our readers, to fit up a small laboratory for conducting investigations bearing upon the pathology of snake-bite and cognate sub-

jects. The Government of Bengal has addressed the Government of India on the subject. If the latter would make a grant of Rs. 5000 towards this object the Lieutenant-Governor of Bengal will endeavour to make up the required balance from provincial funds. As it is understood that Dr. D. D. Cunningham, F.R.S., will take an active part in organising and promoting the necessary inquiries and carrying out the necessary experiments, it is to be hoped that the project will be carried to a successful issue. The various alleged remedies for snake-bite from time to time brought to notice might then be tested.

#### MOVEMENTS OF THE MEDICAL STAFF.

The retirement on retired pay of Surgeon-Lieutenant-Colonel C. E. Dwyer has been cancelled. Surgeon-Lieutenant-Colonel Blood has resumed duty at Winchester from sick leave. Surgeon-Major W. Campbell has assumed medical charge of the camp at Bisley. Surgeon-Lieutenant-Colonel D. B. Brown has rejoined at Piershill, from leave. Surgeon-Major A. A. Lyle has joined at York, from Chester. Brigade-Surgeon-Lieutenant-Colonel R. H. Carew has proceeded from Meera Meer to Kashmir on sick leave, and Surgeon-Lieutenant-Colonel J. D. Gunning from Bareilly to Mussoorie. Surgeon-Lieutenant-Colonel Gabbett has obtained sick leave from Madras. Brigade-Surgeon-Lieutenant-Colonel Riordan is proceeding to England from Cyprus on leave. Surgeon-Lieutenant-Colonel Barrow is expected in England from Hong-Kong, on relief. Brigade-Surgeon-Lieutenant-Colonel T. D. O'Farrell is placed on retired pay. Surgeon-Lieutenant-Colonel Supple has resumed his duties as senior medical officer in Jersey. Surgeon-Captain W. H. P. Lewis has taken up duty at the Arsenal, Woolwich. Surgeon-Captains Sparke, Hall and Burke have respectively left Warley and Colchester on leave. Surgeon-Captain J. J. C. Watson has proceeded to Bisley Camp from Aldershot and D. O'Connell has rejoined at Aldershot from leave. Surgeon-Captain S. R. Wiles has been transferred from York to Chester. The following officers have obtained sick leave to England from Burmah and Bombay severally:—Surgeon-Captains Green and Holyoake. The leave of Surgeon-Captains C. C. Reilly and J. S. Black from Bengal has been extended. Surgeon-Majors Feltham and Asbury have been granted leave to England from Madras. Surgeon-Captain Sexton has joined at the Curragh for duty and Surgeon-Captain Lensham has proceeded to Dublin. Surgeon-Captains H. Thompson and Hanley are under orders for foreign service. Brigade-Surgeon-Lieutenant-Colonel Ignatius McDonogh O'Farrell, F.R.C.S.I., is placed on retired pay (dated June 16th, 1892).—Surgeon-Captain R. C. Johnston, M.B., is placed on retired pay (dated July 6th, 1892).—Surgeon-Lieutenant-Colonel C. E. Dwyer has been appointed to the Recruiting Staff in London.

#### ARMY TITLES AND RETIRED MEDICAL OFFICERS.

An agitation is, we understand, being set on foot to procure for army medical officers who were on the Retired List prior to the issue of the Warrant conferring the new titles the right to assume the titles now enjoyed by their colleagues on full pay. As a considerable number of these officers are liable to be recalled to service on "an emergency," the application is, in their case at any rate, a reasonable one and seems to deserve favourable consideration, as, if it should be refused, complications as to seniority would arise which the concession would promptly avert.

#### INDIAN MEDICAL SERVICE.

The Commander-in-Chief is pleased to make the following appointments:—5th Bombay Cavalry (Sind Horse): Surgeon-Captain J. G. Hojel to the medical charge, vice Surgeon-Captain T. E. Dyson, transferred to the Civil Department.—7th Bombay Lancers (Baluch Horse): Surgeon-Captain J. B. Jameson to officiate in medical charge, vice Surgeon-Captain J. L. T. Jones, on furlough.—2nd Bombay Infantry (Grenadiers): Surgeon-Captain C. T. Hudson to officiate in medical charge, vice Surgeon-Captain A. Milne, transferred temporarily to the Civil Department.—Surgeon-Captain B. D. Basu is posted to general duty, Sind District.

Surgeon-Captain H. I. Pocock, serving in the Bengal Command, has been appointed to the civil medical charge of Roorkee, in addition to his military duties.—The following changes of station have recently taken place:—Surgeon-Majors: C. H. Swayne, Dublin to Londonderry; P. M. Ellis, to Aldershot; P. J. O. Sullivan, Bengal to Dublin; H. Grier, Nova Scotia to Aldershot; A. Harding, Bombay to Aldershot; E. H. Myles, Swansea to Devonport; G. F. A. Smythe, Dover to Canterbury; W. O. Wolsey, to

Chester; P. H. Fox, Madras to Ballincollig. Surgeon-Captains: M. W. Kerin Cork to Dublin; J. G. W. Crofts, Edinburgh to Home District; M. O' C. Drury, Bombay to Aldershot; H. A. de Lom, Dover to Bombay; A. Perry, Home District to Ceylon; H. J. Fletcher, Bengal to Stoneleigh; G. G. Adams, Horfield to Cirencester; J. M. F. Shine, Bengal to Dublin; W. H. Bennett, Madras to Lonford; P. C. H. Gordon, Edinburgh to Ayr; A. L. H. Dixon, Bombay to Aldershot; P. J. R. Nunnerley, Chester to Stafford; C. Garner, Bermuda to Devonport; J. D. Deacon, Ballincollig to Cork; G. A. Wade, Jamaica to Devonport; C. W. R. Healey, Lichfield to Bengal; W. E. Hardy, Colchester to Dover.—The undermentioned Surgeon-Lieutenants have been transferred from Aldershot as follows:—W. G. Beyts, to Edinburgh; S. H. Withers, to Golden-hill Fort; L. A. Mitchell, to Pembroke Dock; J. Henessy, to Horfield; C. B. Martin, to Alnwick; Surgeon-Lieutenant J. M'Laughlin, Sierra Leone to Bathurst; R. Crofts, Sierra Leone to Lagos.

*Bengal.*—The services of the undermentioned Officers of the Bengal Medical Establishment are placed temporarily at the disposal of the Bengal Government:—Surgeon-Captain C. E. Sunder, M.B.; Surgeon-Captain A. H. Nott, M.B.; and Surgeon-Captain J. T. Calvert, M.B.

Surgeon-Major Owen, I.M.S., Medical Officer on Lord Roberts' Staff, has been appointed Civil Surgeon at Ajmere.

The Governor in Council is pleased to appoint Surgeon-Major J. S. Wilkins, D.S.O., to act as Civil Surgeon, Kaira, in addition to his own duties, during the absence of Surgeon-Captain W. H. Quick on privilege leave.

Surgeon R. Baker, M.A., M.D., and Surgeon-Major H. M'Calman, M.D., respectively delivered over and received charge of the Batnagiri Gaol on June 4th, 1892.

*YEOMANRY CAVALRY.*—Ayrshire: Surgeon-Captain W. J. Naismith, M.D., to be Surgeon-Major (dated July 2nd, 1892).

*VOLUNTEER CORPS.*—*Artillery:* 2nd Cinque Ports (Eastern Division, Royal Artillery): The undermentioned Surgeon-Lieutenants to be Surgeon-Captains:—F. M. Wallis and F. H. Shaw (both dated July 2nd, 1892).—*Rifle:* 1st Volunteer Battalion, the King's (Liverpool Regiment): James Charles Bradshaw, Gent., to be Surgeon-Lieutenant (dated July 2nd, 1892).—1st Volunteer Battalion, the Suffolk Regiment: Surgeon-Lieutenant S. S. Hoyland to be Surgeon-Captain (dated July 2nd, 1892).—(2nd Berwickshire) Volunteer Battalion, the King's Own Scottish Borderers: Surgeon-Lieutenant A. D. Vardon resigns his commission (dated July 2nd, 1892).—1st (Pembrokeshire) Volunteer Battalion, the Welsh Regiment: Surgeon-Lieutenant W. H. Lloyd to be Surgeon-Captain (dated July 2nd, 1892).—2nd (Renfrewshire) Volunteer Battalion, Princess Louise's (Argyll and Sutherland Highlanders): Surgeon-Captain W. G. Stevens to be Surgeon-Major (dated July 2nd, 1892).

## Correspondence.

"Audi alteram partem."

### "TOOTH CULTURE."

To the Editors of THE LANCET.

SIR,—In his interesting lecture on "Tooth Culture," Sir James Crichton-Browne enumerates four causes of caries; among them he includes imperfect mastication. He thinks "that the greater prevalence of dental caries in these days is probably in some measure dependent on the softness and pulpiness of the food on which we for the most part feed." I have for some time been strongly of opinion that this is the great cause of caries among the moderns. He points out that soft food means comparatively little mastication and use of the teeth, that the flow of the saliva is thereby diminished and that in consequence, the teeth not being properly cleansed by an abundant flow of saliva, nor by the scrubbing action of the parts engaged in mastication, particles of food are lodged about the teeth and gums and by their decomposition injure the teeth. Few can doubt the reasonableness of that view, but I venture to think that imperfect mastication favours dental caries in another and even more potent way—namely, by interfering with the proper development not only of the jaws, thereby causing over

crowding of the teeth (an acknowledged cause of decay), but of the teeth themselves; and it goes without saying that an ill-grown tooth is more liable to decay than one well developed. This fact is well attested by the early decay of the puny wisdom teeth. That imperfect mastication prevents the teeth from properly developing I can testify from observation, and the manner in which this result is brought about is obvious. With the movements of mastication the jaws become more vascular, there is a large access of blood to the dental arteries, the teeth move perceptibly in their sockets and their blood-supply is greatly increased. They are in fact outgrowths of the jaws, so that it is absolutely impossible to get well-developed teeth in an ill-developed jaw. The teeth in such a jaw may indeed be large, but careful examination of a section of them shows them to be ill-developed. One of the most noticeable effects of imperfect mastication on maxillary development is atrophy of the alveolar processes and early shedding of the teeth. Examine the mouth of a woman—say, from fifty to sixty years old—in a London hospital. It will very often be found that most of the teeth have dropped out and that only two or three remain, projecting far out of their sockets. Such teeth are of course more than useless in that they completely prevent the proper closing of the jaws, which, together with the muscles of mastication, remain practically in a state of disuse. No wonder that alveolar absorption proceeds apace, that the gums are spongy, and the whole interior of the mouth in a loathsome state, a state to which Sir James Crichton-Browne's apt quotation from Shakespeare but too truly applies. Among poor women the teeth are seldom worn down to any appreciable extent, so little have they been used, and indeed among civilised people one never finds the same degree of attrition met with in the teeth of ancient skulls, and this indicates an amount of mastication scarcely less than that of the ruminant. I have little doubt that by a proper use of the jaws in mastication not only might overcrowding be largely prevented, but a healthier development of the individual teeth ensured also and dental caries very considerably diminished. Of the many writers upon the teeth whom I have consulted from time to time Mr. Coleman is the only one who has insisted upon the point I urge—viz., that ill-growth of the teeth, resulting from imperfect use, is a cause of decay. He, however, it is only fair to say, is most emphatic. I would observe in conclusion that the atrophy of the jaws among civilised peoples is only in part the outcome of heredity, that it is in the main acquired by the individual himself, for Weismann, even though he may not have proved that acquired characters are never inherited, has yet made it quite clear that they are not inherited to the degree generally supposed. If therefore an individual were from early childhood to adult age to use his jaws to the same extent as his primitive ancestors used theirs they would develop, if not to the size of the ancestral jaw, certainly to an extent which would surprise many. I look forward, Sirs, to the time when "gymnastics of the jaws" shall be added to other forms of exercise. Meanwhile let us foster the instinct to bite hard things so clearly displayed by children and let us teach the laity to get rid of the "bogey" that the cracking of nuts—the best possible exercise for the jaws and teeth—is injurious to them.

I am, Sirs, yours faithfully,  
Gulford-street, W.C., July 5th, 1892. HARRY CAMPBELL.

To the Editors of THE LANCET.

SIRS,—Will you kindly allow me to remark in reference to Sir James Crichton-Browne's address on Tooth Culture, reported in your issue of July 2nd, that his statement that the "gastro-intestinal mucous membrane of the embryo" forms the "pulp and sacs of the teeth" is not quite correct. Embryologists are generally agreed that the mouth is no part of the primitive alimentary canal, but is formed by an involution of the parts of the face, the enamel being formed from the oral epithelium and epiblastic in origin; whilst the pulp and sac of the tooth, arising from the sub-mucous connective tissue of the mouth, are developed from the meso-blast. The gastro-intestinal mucous membrane is derived from the hypoblast. The teeth have long been known as dermal appendages.

I am, Sirs, yours obediently,  
F. J. BENNETT, M.R.C.S., L.D.S.,  
July 5th, 1892. Assistant Surgeon, Dental Hospital of London.

## "SOME PRINCIPLES TO BE OBSERVED IN THE CLOSURE OF ABDOMINAL INCISIONS."

To the Editors of THE LANCET.

SIRS,—In your leading article upon the above subject (p. 33) you urge that too much attention cannot be paid to the closing of abdominal scars to prevent their subsequent yielding. In the first group of cases you refer to ordinary laparotomy wounds. In these there can be no doubt, if a firm cicatrix is to be ensured, care must be taken to unite all the divided tissues accurately, peritoneum to peritoneum, muscle to muscle, skin to skin. To do this I think it is only necessary to pass the sutures deeply through the parietes on each side of the wound, being careful that the needle properly transfixes each structure. If this rule is attended to there will be no occasion to use the buried sutures, which are tedious to apply and often cause after-trouble.

So important do I consider it to be to bring the muscular surface together that I have long taught the importance, in ordinary abdominal sections, of making the incision slightly to one side of the middle line, so as to ensure the division of the muscle in preference to dividing the tendinous linea alba, which rarely unites firmly, and I have frequently noticed by this latter incision that there is much more tendency to bulging of the cicatrix. I consider it also most essential in all cases to have a well-fitting belt applied before the patient is allowed to sit up. In the second series of cases you allude to—viz., those in which a permanent opening into a mucous canal is to be obtained—I am glad to find you condemn the practice of suturing the parietal peritoneum to the skin. For the last three or four years I have ceased to adopt this course, as I am convinced that it is not only an unnecessary waste of time, but that it is positively harmful, as the cicatrix thus formed is not nearly so firm as when the divided surface of the wound is brought into apposition with the visceral peritoneum. When speaking on this point at the medical societies I have always insisted upon this.<sup>1</sup> As to the means of fixing the viscus to the skin, this must vary according to circumstances, but in the greater number of cases I do not consider it necessary to stitch the visceral peritoneum to the skin. The circumstances which should influence one in this matter may briefly be considered: first, when it is desired to form a permanent fistulous opening, as in gastrostomy and jejunostomy; secondly, in some cases of intestinal obstruction, when it is desired only to drain the distended bowel for a short time to enable a patient to recover strength before a more radical operation is performed; and thirdly, in those cases in which an artificial anus has to be formed. In the first set of cases I am strongly in favour of slinging the stomach or intestine by means of four sutures, placed in the form of a parallelogram, through the serous and muscular coats, passing through the abdominal parietes, two sets on each side of the wound and then through an oval plate with a central opening, the threads being tied on the plate in pairs. Finally, the portion of the viscus enclosed in the parallelogram is drawn through the wound and central opening in the plate and fixed in position by transfixing it with a harelip pin. This operation was described by me at the Clinical Society's meeting and is also fully described in my work, "Surgical Diseases of the Stomach and Intestines." In the second series of cases the plan adopted and so well described by Mr. Greig Smith in his work on Abdominal Surgery should be adopted and in the third series it is not necessary to stitch the viscus to the wound. Every purpose may be attained by drawing a loop of intestine through the incisions in the parietes and passing a suture through the parietes on one side, then through the meso-colon in sigmoidostomy or lumbar colotomy, and finally through the parietes on the opposite side of the incision, the suture being fastened over a bone bar on each side. By adopting this plan there is no possibility of any portion of the omentum or small intestine being forced out of the wound alongside of the knuckle of intestine, the only other sutures necessary being one at each end of the incision, passing through the parietes in the ordinary manner.

I am, Sirs, yours faithfully,  
FREDK. BOWREMAN JESSITT, F.R.C.S.  
Buckingham Palace Mansions, July 6th, 1892.

<sup>1</sup> THE LANCET, vol. II, 1891, p. 987.

**"RHEUMATOID ARTHRITIS AND RHEUMATIC ARTHRITIS."**

To the Editors of THE LANCET.

SIRS,—In referring to Dr. King's letter on this subject in your issue of June 11th, which professes to deal directly with certain statements of mine occurring in a paper read at the Royal Medical and Chirurgical Society, permit me to examine some of his arguments. At the very outset he destroys the sense of the whole context of one portion of my remarks by a misquotation—namely, by the omission of the word "hereditary" in the passage "it [rheumatoid arthritis] is a constitutional disease of debility, invariably having a hereditary history of phthisis or gout or both." I spoke of rheumatoid arthritis "occurring in cases with a strong hereditary history of gout, phthisis or struma," using the word struma to indicate tuberculous affection of any organ or part except the lung. There are so many symptoms present, either acquired or hereditary, sufficient to account for the debility that to investigate and ultimately prove the presence of the bacillus in these would merely corroborate still further my opinions, whereas its absence, while perhaps being somewhat disappointing in cases apparently markedly tuberculous, would certainly not shake my opinion of a wasting and debilitating disease, if certain clinical proofs were not wanting. Dr. King further thinks that acute rheumatism should have greater prominence as a cause of rheumatoid arthritis. Why "comic" that in chronic rheumatic arthritis the young seldom suffer? Does Dr. King think a patient must be old before he can have a chronic complaint? Lastly, in his treatment of giving salicylates in rheumatoid cases, when suffering from increased pain and swelling, it would be interesting to know whether the rheumatic element was conspicuously absent.

I am, Sirs, yours faithfully,

HUGH LANE,

Surgeon to the Royal Mineral Water Hospital, Bath; Hon. July 4th, 1892. Med. Off. to the Royal United Hospital, Bath.

**DEATH UNDER CHLOROFORM.**

To the Editors of THE LANCET.

SIRS,—In THE LANCET of May 21st Dr. Colvin Smith records a death under chloroform which affords a striking example of the danger of pulse feeling in chloroform administration. The patient was breathing well, but, owing probably to the pharynx being full of blood, was rather cyanosed. Although cyanosed he was supposed to have fainted. Simply because the pulse could not be felt ether was injected, and "other steps were at once taken to stimulate the heart." It is clear from Dr. Colvin Smith's account of the case that the heart was refusing to convey any more chloroform to the brain at this time—i.e., while the cyanosis lasted. If the patient had only been left alone, and the safeguard action of the vagus had not been frustrated by the injection of ether, the stoppage of the heart would have saved his life.

I am, Sirs, yours obediently,

EDWARD LAWRIE.

Hyderabad, June 14th, 1892.

**"THE MEDICAL PROFESSION IN PARLIAMENT."**

To the Editors of THE LANCET.

SIRS,—Apropos of the first leading article in THE LANCET of June 25th I enclose the following extract from Col. Lowry's address to the electors of Trinity College, Dublin:—"Next in point of number are the medical graduates. I have always felt that the medical profession has a special claim upon the representatives of the University; for, unlike the legal profession, very few of its members have seats in the House of Commons. It is within my own knowledge that the dispensary medical officers in Ireland have long had reason to complain of their position in regard to both their duties and their pensions. I shall, if elected, give my special attention to the interests of this large and important body." The lawyers want to make a convenience of the electors by making the University a stepping-stone to the bench. Every University doctor should support the advocates of his own profession, as I do, though I am afraid some of them support the lawyers.

I am, Sirs, yours faithfully,

THOMAS MOORE SUNTER, M.D. T.C.D., M.D. Oxon.

Spring grove, Isloworth, July 4th, 1892.

**"STEELE v. SAVORY" FUND.**

To the Editors of THE LANCET.

SIRS,—We beg to forward herewith a third list of donations and subscriptions to the "Steele v. Savory" fund, and in doing so you will permit us to make known through THE LANCET that the Members of the College of the United Services, the Indian Medical Service in particular, have evinced throughout great interest in the justice of the claims put forward by the Association of Members. Surgeon-Lieutenant-Colonel Calthrop, of Mian Mir, Punjab, Bengal Presidency, has issued an appeal and undertaken to receive subscriptions on behalf of the fund and the first instalment was received by the last mail. Surgeon-Lieutenant-Colonel North writes: "I gladly enclose my guinea, and if the sovereign had only cost Rs10, as it should with us, instead of Rs16, I would gladly have sent two, but I shall be happy to contribute further in the righteous cause of the members of the College, and pray communicate my best thanks to the plaintiffs who have been fighting our battle."

We remain, Sirs, faithfully yours,

JABEZ HOGG, } Joint  
W. G. DICKINSON, } Hon. Secs.

July 6th, 1892.

**MEDICAL DEFENCE UNION, LIMITED.**

To the Editors of THE LANCET.

SIRS,—As there appears to exist some misunderstanding as to the position and progress of the Medical Defence Union, Limited, will you allow us to give the following particulars, which will enable the profession to properly judge as to the stability of the Company, its capacity for doing the work of medical defence and for meeting the wants of its members:—

Number of Members.				
1888.	1889.	1890.	1891.	1892 to June.
442	834	1446	1828	2366

Amount of Guarantee Fund.				
1888.	1889.	1890.	1891.	1892 to June.
£538	£1249	£2173	£2826	£3489

The Executive Council of the Union is composed of an equal number of London and provincial members and the meetings are generally held alternately in London and Birmingham. Members of the Union are drawn from the metropolis in large numbers, as well as from all parts of the United Kingdom. One of the secretaries resides in London, one in the Midlands, and in this way cases of emergency can be dealt with with the utmost promptitude and despatch and personal advice given to members resident in London when required.

We are, Sirs, your obedient servants,

LESLIE PHILLIPS, M.D., } Hon. Secs. Medical  
A. G. BATEMAN, M.B., } Defence Union.

July 4th, 1892.

**GREAT YARMOUTH HOSPITAL.**—The annual report for the past year shows that 332 in-patients and 3857 out-patients were treated during the twelve months. The year's income had more than covered the expenditure, leaving in hand a surplus of £220 19s. 11d. The invested funds amount to £16,120 6s. 7d.

## THE FRENCH WORKMEN'S SANITARY CONGRESS.

(FROM OUR SPECIAL CORRESPONDENT.)

ON the afternoon of July 3rd the Congress commenced its labours, which during the first meeting were for the most part of a formal character. The credentials of the delegates had to be verified and the various commissioners elected. M. Prudent Dervillier, a member of the Paris Municipal Council, was appointed chairman. In opening the proceedings he explained that the general programme of the Possibilist Party had been debated at the ten preceding National Congresses and was now so well established and understood that the time had come to deal with practical questions instead of abstract theories. It was the duty of the working classes to study earnestly even dry and technical questions, for on their votes depended the solution of these problems. During the present Congress questions relating to the health of the working classes had been selected for debate.

Workmen, it was true, did not possess the technical knowledge required to deal with these problems, but they had appealed to the Professors of the Faculty of Medicine, who had acquired this knowledge. These eminent men of science were separated from the working classes by many material and social considerations, but they were at one with the working class in seeking to elucidate scientific truths independently of all class interests. As Possibilists the organisers of the Congress wanted to profit by the knowledge of these scientific truths, to demand in the name of science, of humanity, of public health, such laws as shall guarantee to the working classes pure unadulterated food and wholesome dwellings. The workers would then have more intellectual and physical strength; they would then be better able to grapple with those great social and economical problems that went to the root of all the evils from which society suffered.

M. A. Lavy, Deputy for Montmartre and general secretary for the Congress, read the correspondence, showing how widely the object of the Congress had been approved. A few reactionary papers had blamed the workmen for abandoning their scarecrow revolutionary policy. They had abandoned none of their aspirations, but wanted to render workmen fitted for a better future by improving the material conditions under which they now lived.

Some discussion ensued as to whether delegates from the Society of Veterinary Surgeons and from the philotechnic associations should be admitted. These delegates had important communications to make in respect to the teaching of hygiene and the control of the supply of meat. It was ultimately decided that as the delegates did not represent labour organisations they would be welcomed as guests and might submit communications, but could not assist as delegates. As instructors and as guests the representatives of all scientific societies were most welcome—as delegates they could not be accepted for they were not labour representatives.

On the second day M. Lavy, Deputy, was elected chairman and announced that the municipality of Rochefort-sur-Mer had voted a subvention to send delegates, and that delegates had arrived from St. Etienne and from Lyons. He had also to welcome Mr. James Holmes of the Leicester Trades Council. In reply Mr. James Holmes explained that the workers of England took great interest in the Congress and would have sent a numerous deputation but for the general elections. If the first necessity was to obtain good wages the second was to be able to lay out those wages advantageously. The Congress by dealing with the question of the adulteration of food would help to solve this latter part of the labour problem. Some discussion arose as to whether the delegates of a society of cooks could be admitted, because two employers of labour were members of that society. This association is called l'Académie de Cuisine, a title which amused and found favour with the Congress, and it was decided that, as the immense majority of the members were workers, they should be allowed to send delegates to represent their "art" in the Congress.

The discussion was now opened on the first question—the food of the working classes. M. Roland, representing labour organisations of the Port de Flandres districts, said they did not believe much would be done to better the quality

of the food workers were in the habit of buying. Here and there individual tradesmen would endeavour to act honestly, but the intervention of the State was much preferable to individual effort. The scientific lectures delivered in preparation of the Congress proved that many workers did not earn enough to buy the amount and quality of food necessary to keep them in health. Some suggested total abstinence as a remedy, though it had been shown how often the drinking of water was the cause of typhoid fever. Others proposed vegetarianism, while some employers of labour had gone so far as to suggest that the fasting experiments of Succi might indicate how working-men could live cheaply. Against all these proposals he protested energetically and urged that the real remedy rested in the establishment of a minimum rate of wages based on scientific calculations as to what was necessary to keep workmen in good health. Official science had condemned vegetarianism and total abstinence. But, even if the workmen had sufficient wages to procure meat diet and wine, what was to prevent them from being poisoned by, for instance, the bad alcohols added to the cheap wines? He deeply regretted that the French Chambers had not voted in favour of the proposal to create a State monopoly in alcohol. He thought that the municipalities might open depôts for the necessities of life—meat, bread, &c.—and, as there would be no trade interest to serve in adulterating these articles when they were sold by the elected representatives of the community to the community, there would then be a fair prospect of getting wholesome food.

The delegate of the third arrondissement of Paris complained of the facilities existing for the practice of adulteration. Why was theft of this description so easy? Bread contained 40 to 42 per cent. of water when it should not contain more than 30 to 32 per cent. Then the baker also succeeded by various manoeuvres in giving light weight. The workers had no practical means of preventing this daily robbery of their class. Butchers gained 125 per cent. per annum on the capital they engaged in their trade; and competition, the panacea for all evils, according to the teaching of the orthodox economists, had not improved the situation. The number of butchers and bakers was daily increasing, but the prices continue to rise. The real competition wanted was that of municipal butcheries and bakeries who would sell in the interests of the public and not of trade.

Dr. Paul Brousse, Municipal Councillor and representative of the Epinette district, discussed the qualities of the food required so as to maintain the human equilibrium and showed what was proved to be chemically necessary. Money would not always secure this, and even those who could afford luxuries might be underfed or poisoned through the bad quality of what they bought. Pastry might be coloured with copper or arsenic and bread poisoned with the lead coming from the paint adhering to the wood of old houses sometimes used to heat the ovens. Competition had made matters worse. Bakers spent in shop windows and ornamentations to attract customers what they ought to spend in the flour for their bread. People had to pay for the big shops, the flaring gaslights and the big advertisements, and thus did not get their money's worth in food. He agreed with the previous speakers that they wanted the establishment of public services for the necessities of life. But it would not be wise to rest, as it were, hypnotised by this grand conception. Pending the municipalisation of those trades on which public health depended—water, bread, meat, &c.—they must endeavour to obtain stricter laws against adulteration. Alphonse Karr had wittily remarked that if he were to rob his grocer he would certainly be sent to prison, but if he proved that his grocer had robbed him by selling him an adulterated article the grocer would only be fined. If in his indignation he went and killed the grocer he would be arrested, convicted of murder and guillotined, but if he was killed by the grocer selling him an article adulterated with poison the grocer would again escape with a fine. In the Middle Ages, Dr. Brousse urged, adulteration was classed with the coinage of false money, and the culprits were in both instances hanged. Doubtless the municipal analytical laboratory would help to moralise trade, but he suggested that articles of food—such as for instance a cask of wine—should be accompanied by a sort of bill of health, or passport, on which its history should be recorded, so that as it changed hands it might be seen by whom its original quality and character had been altered.

Madame Bertier pleaded for good food for workwomen. It was a deplorable fact that the majority of the workwomen of

Paris were anæmic. How could they give birth to healthy children? Where would France find the soldiers for its future battles? A few workwomen earn enough—they are the exception, and the workwomen who were strong and well fed had such personal charms as enabled them to obtain money from other sources than labour. Even when a workwoman, in consequence of very exceptional taste or skill, could earn enough to buy wholesome food she had not time remaining to cook it properly. Had the underpaid and underfed workwomen of Paris the right to be mothers when they had neither the time to tend their children nor the health to bear them? It was now proposed to enforce rest on Sunday, but this meant no rest for women. Early on Sunday morning the women had to go to the washhouse with the week's dirty linen; then they had to come home and cook and the afternoon was spent in mending the clothes. Sunday was often the hardest day of the week. But there were no two measures in nature—women wanted food and leisure as well as men. She urged that women ought not to compete with men by doing the same work for less wages. A law should be passed making it illegal to employ any woman for less than half a franc per hour. Women might then work three hours in the morning, three hours in the afternoon, gain three francs (or 2s. 5d.) per day, and yet have some time remaining to attend to domestic duties. This Madame Bertier thought should be the very lowest scale of wages the law should sanction.

A communication from M. Tessignier and coming from the Society of Veterinary Surgeons was then read. M. Tessignier insisted on the quality of meat. This was more important than the quantity. In France the soldier was allowed 300 grammes of meat. This was not enough and yet the workman often did not get as much. Then it was bad meat—not absolutely unwholesome, but flesh of old, tired cattle—meat that loaded and embarrassed the stomach without strengthening the system. The meat might be wholesome when it came from the slaughter-house, but it was often unwholesome by the time it was sold. Horse was sold for beef, dog for mutton; accidents and illness resulted, but attracted no attention unless they occurred on a wide scale. Then measures were taken, but they were only temporary in their effect. Yet the workman's only capital was his health. Such laws as existed for the inspection of meat were aimed against great epidemics rather than against evils that occurred but in detail. Nor did the Legislature define the meaning of the word "corrupt" and the verdicts given were most contradictory and uncertain. What is condemned in one town is allowed in another. Municipal by-laws, though often the result of very serious study, are obscure and incomplete. As the Congress represented the working classes, who were the principal sufferers, it must insist on better and more clearly defined laws. A better watch must be kept over private slaughter-houses. In these small places horse was easily substituted for beef and dog for mutton. In all towns with more than 5000 inhabitants private slaughter-houses should be abolished and a public slaughter-house erected. Then there should be a fully qualified veterinary surgeon attached to each public slaughter-house. At present inspectors of slaughter-houses were appointed in consequence of their political opinions and with no regard to their technical knowledge. Some of the meat which is condemned in Paris is forthwith sent to provincial towns, where the inspection is less severe. It is also very difficult to detect bad meat when the worst parts have been previously and carefully removed. It is therefore necessary that there should be a large staff of thoroughly qualified veterinary inspectors and that the law affecting the control of the meat-supply should be strengthened, more clearly defined and rendered uniform.

The Congress then adjourned, as it was close upon midnight.

## BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

### *The Medical School.*

THE union of Queen's and Mason Colleges for the purposes of medical teaching is now an accomplished fact and the result is looked forward to with hope and confidence in the future. The gain will undoubtedly be to the students from every point of view, for the amalgamation will produce a solid and substantial basis which must effect strength. At a meeting of the Council, held on the 5th inst., the following

three vacancies in the faculty of medicine were filled up: To the Professorship of Medicine, Dr. R. Saundby; to Ophthalmology, Mr. Priestley Smith; and to Dental Surgery and Pathology, Mr. F. E. Huxley. These appointments will give general satisfaction.

### *Scalding Fatality.*

"What dire events from trivial causes spring" is probably no more forcibly exemplified than in the cases of burns and scalds. Oftentimes miners have been known to walk home after being badly burnt and to die very soon afterwards. With children, too, it is well known what a small amount of burning is sufficient to place their lives in great danger. An instance lately happened to illustrate this in the case of a woman on whom some hot water was thrown by another woman. The patient walked to the General Hospital and was detained there. After a few weeks erysipelas set in; the patient is now dead, and her assailant stands charged with manslaughter.

### *White Cross Society.*

A meeting of this Society was held in the Town Hall on June 30th and was well attended; the Bishop of Wakefield occupied the chair. Among the speakers was Dr. Malins. A vigorous effort is being made to extend the influence of this movement in the town. No nobler objects of a social kind could be aimed at than those this Society seeks to enforce—greater purity among men, a chivalrous respect for womanhood, and a higher tone of public opinion. The want of these attributes in society of the present day is an obvious fact to all reflecting persons, and any attempt to remedy such a condition of affairs will be welcomed with all sincerity.

### *The Society for the Prevention of Cruelty to Children.*

This Society is seeking to enlist public support by holding meetings in and around the town, where sympathy in its work and efforts is earnestly solicited. The records of our criminal courts show the prevalence of the evils and dangers attending the growth of the young in our community. With regard to the protection of infants and children there is still abundant room for progress and the efforts made by this Society cannot fail to be productive of good.

July 6th.

## LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

### *Hospital Saturday in Bootle.*

THE institution of Hospital Saturday has been found to be a most important adjunct of Hospital Sunday. Many persons are prevented by the nature of their avocations from attending church or chapel, while many probably do not attend though quite able to do so. In Bootle last year an experiment was made of a somewhat original idea. Boxes resembling hospital cots were placed in the streets in conspicuous localities; these realised a sum of £227. This year the experiment has been repeated with even better results, £308 having been received. This happy thought seems worthy of adoption elsewhere.

### *The Candidature of Dr. B. W. Richardson.*

It is much to be regretted that Dr. B. W. Richardson, who would have been such a valuable acquisition to the House of Commons, was not induced to try for some seat which he was more likely to win. His candidature for Walton was from the very first hopeless, but there must be elsewhere in the country seats where his political and other views would be more acceptable, and it is to be hoped that we may yet find his name added to those of the other gentlemen who will represent the medical profession in the new House of Commons.

### *The Water-supply of Liverpool.*

On the 14th inst. the Duke of Connaught and Strathearn will inaugurate a most important event to Liverpool—the opening of the new water-supply from Vyrnwy Lake. At the first census in 1831 the population of Liverpool was considerably less than half of what it is now and local reservoirs sufficed for the water-supply. But for years past these have been wholly inadequate and the residents have been put to most serious inconvenience by the authorities reducing the water-supply to a few hours a day of service sometimes and frequently to half-service. It is very satisfactory and very creditable to the sanitary authorities that it did not lead to an epidemic of

typhoid fever. The constant service is on now and we have every reason to hope that it will be continued in future without any break. The formation of the aqueduct for conveying the water a distance of seventy-seven miles from the lake to the heart of Liverpool has been a great engineering feat, comprising the formation of tunnels, reservoirs, and water towers along its course. The carrying of the water under the Mersey was the most formidable part of all, requiring almost superhuman efforts to overcome the difficulties. The work has been costly, of course, but the money will be well spent in providing the city with an abundant and never-failing supply of good water.

July 6th.

## NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

### *The Newcastle Royal Infirmary.*

A PUBLIC meeting in response to a requisition of citizens was held last week under the presidency of the Mayor to consider the proposal of the house committee to erect new buildings to perpetuate the memory of the late Dr. Bruce, the eminent antiquary and philanthropist of this city. It was stated at the meeting that a new infirmary would probably cost something like £100,000 and that under the existing depressed state of trade it would be hardly wise at present to ask for such a sum. At the same time a new infirmary was admitted want, and the feeling of the meeting was that a commencement might be made in the way of building a new wing or pavilion to be called the "Bruce wing." This would, it was stated, cost from £5000 to £7000. Dr. Philipson, in seconding the motion for the erection of the proposed Bruce wing, stated that the present building was in parts over 150 years old; and when they reflected on the changes that had taken place in the institution from time to time he thought it would be felt that the time had come when very decided action should be taken with respect to the infirmary if its position and prestige were to be maintained. It was also resolved to erect the new infirmary, if it can be so called, upon the present site, which in the opinion of many is open to serious objections; indeed, our medical officer of health was hardly, I think, satisfied with the existing space. Mr. Alderman Newton, surgeon, raised the question as to the allocation of the students' fees between the teachers and the treasurer of the infirmary, but the point was ruled out of order by the Mayor. It is right to mention, as regards the internal economy of the infirmary, that there is a growing feeling here among the profession that some reforms are necessary in the interests of subscribers, the profession, and indeed of the public. For instance, it is thought that relief is given far too readily to casuals well able to pay, that the honorary medical appointments are too exclusively held in connexion with the medical college and that the said appointments are held for too long a period. There are many other points giving rise to discontent, which, however, may be referred to at another time.

### *Raby Castle Sanitation.*

The *Northern Echo* states that Lord and Lady Barnard, who only lately succeeded to and took possession of Raby Castle, will not resume residence there again for some months, until the sanitation of the castle is thoroughly overhauled. The castle is a very ancient pile; some few years ago its condition was a subject of consideration by the sanitary authority.

### *The Bequests of the late Dr. G. Y. Heath of Newcastle.*

The *Newcastle Journal*, in reference to the munificent bequests of the late Dr. Heath (first announced in these "Notes" a few weeks ago), states that the Royal Keper Grammar School has been also favoured to the extent of about £5000 to found a medical scholarship from the school to the Newcastle College of Medicine. The Keper Grammar School at Houghton-le-Spring, near Sunderland, is so named from the fact that in 1574 a Mr. John Heath, in conjunction with the then rector, the celebrated Bernard Gilpin, gave certain tithes which formerly belonged to Keper Priory near Durham for the foundation and maintenance of the school. It should be stated that the will of the late Dr. Heath, if proved, has not, at all events, yet been made public, so that there may be other educational surprises in store.

### *Presentations.*

Dr. Carlyle, Langholm, has been publicly presented with

his portrait (painted by Sir George Reid, President of the Royal Scottish Academy), the occasion being the completion of fifty years' medical practice in the town.—Dr. Smith of Ryton has been presented by his pupils of the ambulance class with a handsome hall clock.—Dr. Wm. Slater of Newcastle has also received a presentation.—Dr. A. D. Mucintyre of Conselt has been the recipient of a testimonial, subscribed for by the railway servants' ambulance class at Conselt and Blackhill.

Newcastle-on-Tyne, July 6th.

## SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

### *Complimentary Dinner to Mr. Charles Smith, of Kinnairdy, Banff.*

ON July 2nd Mr. Charles Smith, M.R.C.S., was entertained at dinner by his professional brethren in the Palace Hotel, Aberdeen, on the occasion of his celebrating his jubilee as a medical practitioner. Over sixty gentlemen sat down under the chairmanship of Dr. Angus Fraser of Aberdeen. The toast of the evening, "The Health of the Guest," was enthusiastically pledged, and Mr. Smith in reply gave a highly interesting account of medical practice fifty years ago and its gradual development and improvement. A few days previously Mr. Smith was met by the leading inhabitants of the district where he has so long and ably conducted practice and was presented with a very handsome testimonial.

### *Health of Aberdeen.*

The state of health last week was very satisfactory, except for an epidemic of measles at Torry, one of the fisher quarters of the town. Scarlet fever is on the decrease, and diphtheria is represented by two cases, while there are no cases of puerperal or typhus fever.

July 6th.

## IRELAND.

(FROM OUR OWN CORRESPONDENT.)

### *Dublin University Tercentenary.*

DUBLIN is very busy this week on account of the celebration of the tercentenary of Trinity College. The first of the festivities was commenced on Monday evening by Dr. Kidd, President of the Royal Academy of Medicine, and Mrs. Kidd giving an "at home" at their residence in Merrion-square. A very large number of guests were present, who spent a very enjoyable evening. Music added to the attractions of the evening, the principal vocalist being Mr. Barton McGuckin.

### *Royal College of Surgeons.*

The Honorary Fellowship of the College will be conferred on the 7th inst. upon the following gentlemen—viz., Thomas Bryant, President of the English College of Surgeons; John Shaw Billings, Surgeon-General, United States Army; Professor Adolphus Gusserow, Berlin; and Hermann Snellen, Rector Magnificus, University of Utrecht. A meeting of the College will be held on July 11th, convened by requisition, to take into consideration the whole question of advertising and to decide, if possible, what is within the limits of professional propriety. His Excellency the Lord-Lieutenant will on Friday, the 8th inst., unveil the memorial bust of the late Dr. Robert McDonnell, the eminent surgeon and physiologist, and former president of the College.

### *Irish Medical Schools and Graduates' Association.*

The annual dinner of the Association was held recently in the Royal Marine Hotel, Kingstown, the chair being occupied by Dr. Mapother, of London, in the absence of the president, Mr. Dick, C.B., Director-General R.N. The chairman, in proposing the toast of the guests, specially alluded to Professor Hæshagen and Mr. Bruce Joy, the eminent sculptor. Mr. Bruce Joy, he said, was the son of one of the most popular Fellows of the College of Physicians and the sculptor of the bust of their beloved and lately deceased colleague, the great Robert McDonnell. The chairman, in giving the toast of "The Irish Medical Schools and Graduates' Association," mentioned that the Society could now boast a membership of 700, and concluded by alluding to the grievances of Irish graduates in regard to certain hospital appointments, which were, however, gradually being removed. The toast

of the chairman (Dr. Mapother) by Sir Charles Cameron terminated the proceedings.

#### *Health of Ireland: March Quarter.*

The births registered amounted to 26,978 being 1.2 under the average for the corresponding rate of the ten years 1882-91. The deaths were 30,660, equal to 26.4, and the highest rate recorded for any quarter since registration was established (in 1864), and is 22 per cent. in excess of the average rate for the March quarter of the past ten years. This increase in the mortality principally occurred among persons of advanced ages. The high mortality was due to the prevalence of influenza and pulmonary affections and to the severity of the weather. Measles and whooping-cough were prevalent in the Dublin and Belfast districts, but there was a considerable falling off in the deaths from typhoid fever in the Dublin registration district. It may be mentioned that the Dublin Corporation have agreed to schedule whooping-cough and measles among the list of infectious diseases to be notified.

#### *Report on Dublin Hospitals.*

The thirty-fourth annual report of the Board of Superintendence of the Dublin hospitals has been presented to the Governor of Ireland. The Board have visited the hospitals to examine into their condition and to ascertain if proper care were bestowed on ventilation and on the proportion of inmates to space. They report that the nursing organisation is now generally efficient and have suggested that due provision should be made for the nurses' comforts as far as possible and that their food-supply should be carefully attended to. They also express a hope that an institution connected with the hospitals should be endowed and equipped for pathological, chemical and bacteriological research. They state that such an establishment is urgently needed in the interests of medical science, for medico-legal investigations and for the benefit of the community at large.

July 5th, 1892.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

#### *The Choleric Epidemic.*

SOME weeks ago I had occasion to refer to an outbreak of cholera nostras at Nanterre, a western suburb of Paris. The epidemic has since extended its ravages to adjoining suburbs situated in the west and north-west of the metropolis and a certain number of cases have been met with in Paris itself. From April 5th (the date at which it commenced) to June 25th the epidemic has been fatal in 159 instances. That the number of persons attacked has not been very considerable is apparent from the heavy mortality reported from such centres as Nanterre (44 deaths out of 55 cases) and Argenteuil (13 out of 19). In my previous communication I promised to send you the results of the bacteriological examination of the organs of the Nanterrois who succumbed at the Hôpital Beaujon. These researches, conducted by M. Netter, a very competent authority, are now completed, and it appears that a bacillus discovered in the intestines presented great similarity to the micro-organism of true cholera. Both the Conseil d'Hygiène and the Comité Consultatif d'Hygiène Publique have investigated the matter and these bodies are unanimous in regarding the consumption of Seine water as the efficient factor in the production of the outbreak. They strongly urge the authorities to submit this dangerous stuff—Seine water—to the process of boiling previously to supplying it to those of their customers who are condemned to the ordeal of consuming it. The excessive heat which has lately prevailed has doubtless stimulated the growth and multiplication of the numerous micro-organisms contained in water the periodical distribution of which in Paris is a crying scandal and a reproach to those responsible for the physical well-being of the inhabitants of *la ville lumière*. Meanwhile I think I am justified in stating that the outbreak in question is *not* cholera morbus, and that intending visitors to this gay centre of pleasure need be under no apprehension of contracting the severe form of diarrhoea which is always more or less in our midst at this time of year, provided they refrain from drinking unboiled and unfiltered Seine water.

#### *Recrudescence of Typhoid Fever in Paris.*

*L'eau de Seine* and enteric fever are old and staunch allies, and the turning-on of the water is equivalent to the turning-

on of the disease the existence of which is a disgrace to a Hnuismannised city like Paris. Is it to be wondered at then that cases of typhoid fever should be beginning to pour into the hospitals in increasing numbers? Dr. Monod reports to the Comité Consultatif d'Hygiène Publique that the number of persons with this disease admitted into the Paris hospitals from June 24th to June 30th was ninety-five. On the morning of June 24th there were under treatment in the wards of our hospitals 185 typhoid fever patients; on the evening of the 30th ult. these figures had increased to 235. If these poor sufferers were under treatment for wounds inflicted by roughs in the streets loud demands would soon be forthcoming for the repression of such lawlessness. But when death and disease are distributed through the medium of pipes amongst our population the dire results are accepted as a matter of course and no outcry is emitted by the public against such a scandalous régime. The patient long suffering of the Paris public is simply beyond British comprehension.

#### *Inter-University Courtesies.*

At the usual monthly meeting, held last week at the Sorbonne, of the General Council of the Paris Faculties it was decided to present a congratulatory address to the University of Dublin on the occasion of the tercentenary festivities which are being held this week in the Irish capital. Our distinguished confrère, Professor Lannelongue, was delegated to speak at the banquet in the name of the Paris University. Professor Lannelongue's visit to Dublin will doubtless have the effect of further interesting the hospital surgeons of that city in his sclerogenic method of dealing with tuberculous lesions.

#### *An Anti-Cancer League.*

In March last Professor Verneuil suggested to his colleague Professor Duplay the idea of forming an association the *raison d'être* of which should be the elucidation of the real nature of carcinoma. The idea has now been acted upon, and a committee has been appointed to further the development of this deserving enterprise. The committee includes such well-known workers as Duplay, Trasbot (of the Veterinary School of Alfort), Metchnikoff (of the Pasteur Institute), Reclus, Ricard and Brault, with M. Masson (the publisher) as treasurer. These gentlemen have just issued an address to the public exposing therein the objects of the League and asking for subscriptions in aid of researches. An appeal for collaboration is made to pathologists, clinicians, histologists, microbiologists, veterinary practitioners and even geographical explorers. Congresses will be periodically held in order to discuss the progress made in bringing to light any information concerning cancer, a journal will be published as the organ of the League, and, when funds permit, prizes will be offered for any discovery bearing on the subject. I can only wish the enterprise success in its arduous mission.

Paris, July 6th.

## BERLIN.

(FROM OUR OWN CORRESPONDENT.)

#### *The Twentieth Congress of German Medical Men.*

THE twentieth Congress of German medical men met at Leipzig on the 27th ult. It was attended by 104 delegates, representing 149 societies. Dr. Graf of Elberfeld presided. Dr. Busch of Krefeld reported the proposals of the business committee regarding the relation of medical men to trades unions. At the second meeting of the Congress Dr. Branser of Ratisbon reported on the relation of medical men to the offices for the insurance of the aged and infirm. The well-known Berlin gynaecologist, Dr. Martin, proposed that the business committee of the associated societies of medical men should be instructed to describe the circumstances of the medical profession without reserve in the papers every year at the time when the pupils of high schools are examined for the certificate which admits them to the universities, and urgently to warn all those who have no special aptitude for study, particularly those who look to medicine as a means of earning a livelihood. This proposal was rejected by a majority of one, and the declaration that, considering the difficult circumstances of the medical profession, the increase of the number of medical men is out of all proportion to the increase of the population, was adopted in its stead.

#### *Cholera.*

The Government organ, the *North German Gazette*, writes:

"In order to prevent misunderstandings or alarming conclusions, to which the news of measures to ward off cholera may lead, it may be stated that there is no reason for uneasiness either for the present or for the future so far as it can be foreseen, because our frontiers are separated by vast spaces from the region where cholera is now raging, and the pestilence has not shown the slightest tendency to spread in the direction of central Europe. Moreover, the sanitary measures in question are of old date and so arranged and prepared for that they can be completely enforced the moment they become necessary. The danger of an unobserved introduction and spread of the pestilential germ on German soil therefore seems absolutely excluded."

*Dr. Snell.*

The eminent alienist, Dr. Snell, director of the Hildesheim Asylum, near Hanover, died on the 12th ult., aged seventy-four. He was the first in Germany to use agriculture as an element in the treatment of insanity. He is succeeded by his assistant, Dr. Gerstenberg.

*Professor Anton Biermer.*

Professor Biermer, till lately director of the Medical Clinic in Berlin, died the other day at Schöneberg, near Berlin. He wrote on sputum, leucocythæmia, the anatomy of bronchiectasis, pneumothorax, the diseases of the bronchi and of the parenchyma of the lungs, asthma bronchiale, typhus abdominalis, the causes of epidemics, especially cholera, metallic tinkling &c. He taught at Würzburg, Berne, Zurich and Breslau. His successor in Breslau is Professor Kast, formerly of Hamburg.

*Ozone and Influenza.*

At the general assembly of the German Meteorological Society, which met at Brunswick last month, Dr. Eydram of that city communicated that he had measured the ozone of the air during the last twelve years, latterly in and near Brunswick. He had found that at the time of the recent influenza epidemics the amount of ozone in the air was extremely small, hardly 10 per cent. of the normal amount.

*Miscellaneous News.*

The number of medical students in Berlin University this half year is 1448.

Professor Schnaer of Zurich has been called to succeed Professor Flückiger in the chair of Pharmaceutics in Strasburg.

Dr. Fritz Moritz has been promoted to the rank of professor and appointed director of the medical consulting clinic of Munich University.

Professor Fischer of Würzburg has accepted a call to Berlin.

Dr. August Haupt has published a book entitled "Soden am Taunus" (Soden at the Foot of the Taunus Mountains), giving full information about the climate and the waters of that beautiful watering-place.

The Royal Medical Academy of Belgium has elected Professor Du Bois-Reymond of Berlin a corresponding member.

The Society of Prussian Medical Officials will hold its general assembly in the Langenbeck House here on September 5th and 6th.

A committee of scientific men of all nations, including Du Bois-Reymond, Helmholtz, Waldeyer, Hückel and Billroth, has published an appeal for contributions to a monument of Ernst von Brücke in Vienna. Contributions may be sent to Professor Exner, 17, Schwarzspanier Strasse, Vienna, till the end of this month.

The magistrates of Berlin have ordered that all articles sent for disinfection to the municipal establishment for that purpose must be packed in strong chests lined inside with sheet-metal.

Berlin, July 5th.

## EGYPT.

(FROM OUR OWN CORRESPONDENT.)

*Visit of the Khedive to the Government Hospital.*

ON May 19th the young Khedive paid his first visit to Kasr-el-Aini Hospital, devoting an hour and a half to careful and intelligent inspection. He talked with some of the patients in Arabic, explained some new inventions to his aides-de-camp in Turkish and conversed freely with members of the hospital staff in English, French and German. He was much interested in certain operation cases, such as tracheotomy and gastrostomy, in the arrangements for

disinfecting and washing the private clothes of patients, in an excellent machine for sterilising milk, in a German bandage cutter and roller, which allows 5000 bandages to be made daily by one man for the provincial hospitals, and in the new bacteriological laboratory just opened under Dr. Kaufmann's care. His Highness was also interested in seeing cultures of cholera, diphtheria, &c., and in hearing of experiments on rabbits to secure immunity from tetanus. He has since spoken in the highest terms of appreciation of the work done by the English there.

*Cairo Drainage Scheme.*

It may be remembered that in 1889 the Egyptian Government considered its finances sufficiently satisfactory to be able to entertain the cost of draining the capital, thus doing away with some of the existing cesspools and endeavouring to reduce the rate of mortality among the natives. Accordingly Mr. Baldwin Latham was invited to visit Cairo, and he prepared here a carefully worked out scheme. But Egypt has no power to spend her own money upon any new work without the unanimous consent of six Powers, and France at once, though standing alone, refused the necessary permission. After many ineffectual attempts to overcome this difficulty, France eventually agreed that Cairo might spend half the octroi tax of the city, provided that a Commission appointed by England, France, and Germany should unanimously decide upon a good scheme. The French further insisted that if the three engineers were not unanimous a Belgian arbitrator should be appointed. In February last the international trio met in Cairo. They were Mr. Law, chiefly known for engineering works in Brazil; Herr Hobrecht, the designer, constructor and chief engineer of the Berlin sewers; and M. Guérard, the engineer of the Port of Marseilles. Thirty plans already in existence were laid before the Commission and all were judged incomplete or inapplicable to Cairo; but three were praised above the others and therefore the Government prize of £300 has been divided among them. One of the successful competitors is Mr. John Price, sanitary engineer to the Government, and he has also been given the grade of Bey. The Commission then elaborated their own scheme, which they calculate should not cost more than £500,000. But as they did not attempt to enter into any details it will require some months' hard work to determine whether this estimate is a correct one. The Commission recommend, as was anticipated, the system *tout à l'égout* and the formation of a large sewage farm in the desert to the north-east of the town. They propose to divide the city into four great zones, through each of which should flow a main sewer to receive by gravitation the sewage of the zone. These four sewers are all to end in one station, about half a mile to the north of Cairo. Hence the sewage should be pumped to a certain height, from which it should be forced as rapidly as possible through a succession of cast-iron pipes till it reaches the desert land to be irrigated. They particularly insist that the flow through these pipes is to go on continuously by day and night, without disinfection or contact with air. They also veto the manufacture of poudrette, into which the cesspool contents are at present converted in a secluded spot in the desert. They rather cleverly propose to utilise the Khalig by building one of the main sewers under its bed. This Khalig is an open drain running through some of the most crowded parts of the city; it is much older than the Mussulman religion and has nothing to do with it, but unfortunately the religious devotees here are of a contrary opinion and resent any attempt to close it. The commissioners finish their report by noticing the faulty position of the intake of the water-supply from the Nile, and by decreeing that houses unfurnished with proper water distribution shall not be permitted to be in connexion with the new sewers. They recommend further that public latrines shall be provided in greater number, that the mosques and native drinking fountains shall be improved, the levelling and metalling of streets in the native quarters and the opening out as far as possible of new streets to act as ventilating shafts for the crowded districts. Mr. Latham's hydraulic scheme was rejected by the Commission on the grounds of its cost (£500,000) and of its requiring complicated machinery at twelve stations in the town itself, where the sewage must be collected and disturbed. Here it may be remarked that Mr. Latham's scheme was to carry away 15,000,000 gallons of sewage per day, while that of the Commission is to remove eight times as much; it must therefore be that the former scheme was

very expensive or that the new one is extraordinarily cheap. The Commission arrive at their high figures by calculating a sewage flow of 0.4 litre per second per hectare, while for rainfall they allow 3.4 litres; that is, their daily allowance is for nearly nine times more rain than sewage, yet they distinctly point out that the annual average rainfall of Cairo during the last ten years is an inch and a quarter. It is suggested that they have proposed to design their sewers in consequence of one tropical shower of rain, with hail and thunder, which fell during seventy minutes last December. This is as bad as one of the competitors for the Government drainage prize, who assumed that we had a tropical rainfall to provide for. Then, again, the Commission find that Cairo consists at present of an area of 1630 hectares, and they elect to calculate that there are 400 people to each hectare. This gives us a density of population 63 per cent. over and above the 374,000 we now have. There are some arithmetical errors in the report which may have been caused by linguistic difficulties. But we must be grateful to the Commission, for without them Cairo would still have to wait for its preliminary plans, for which the Public Works Department has now been granted a credit of £2000. \*Deducting the cubic cesspool contents which are removed from the better houses in Cairo, there still remain some 100,000 cubic metres of sewage every year which soak away into the subsoil water. On the other hand, out of some 56,000 houses in Cairo there are only 4300 which receive good water from the water company; the remainder are dependent on wells and on water-carriers, who bring the water from wherever they think fit. There are thus some thousands of native houses in Cairo which either have no water at all or are dependent entirely on wells dangerously contaminated by sewage. It is to be hoped that Fiend Cholera is not aware of these facts. The natives seem to enjoy an extraordinary immunity from enteric fever, but their great mortality is largely dependent upon other filth-producing diseases, such as diarrhoea, dysentery, diphtheria, bilharzia and lung diseases. The English inhabitants of Cairo, who take a little trouble about their drinking-water and sewage removal, live as healthily as in London.

Cairo, June 21st, 1892.

## ROYAL COLLEGE OF SURGEONS OF ENGLAND.

### THE ELECTION TO THE COUNCIL.

THE fourth election of Fellows to fill vacancies on the Council of the College, under the new regulations, voting by means of proxy papers being now permitted, was held in the Library of the College on the afternoon of Thursday, the 7th inst., from two to four o'clock and resulted as follows:—

THOMAS SMITH ... ..	285	(including 2 plumpers).
JOHN TWEEDY ... ..	237	" 21 "
ARTHUR EDWARD DURHAM	203	" 8 "
F. HOWARD MARSH ... ..	200	" 0 "
Henry Morris ... ..	188	" 8 "
Jeremiah Macarthy ... ..	106	" 9 "
William Anderson ... ..	90	" 1 "
Alexander Oberlin MacKellar	86	" 3 "
J. Warrington Haward ... ..	77	" 18 "
George Cowell ... ..	75	" 4 "

Mr. Thomas Smith and Mr. Durham were therefore declared to be duly re-elected, and Mr. Tweedy and Mr. Howard Marsh to be elected, members of the Council. More interest was taken in the election than was the case last year, for 149 Fellows attended and voted in person; more were also present at the announcement by the President of the result of the poll. With regard to the use of proxy papers, it appears that 437 were applied for, but only 367 were returned; last year 322 valid proxy papers were sent in and 119 personal votes were recorded.

Mr. H. B. Robinson and Mr. E. C. Stabb acted as scrutineers of the ballot.

### IMPROVEMENTS AT THE COLLEGE.

Those of our readers who visited the College on Thursday and went into the museum must have been much impressed with the important improvements effected by the addition of the new rooms. Proceeding through the doorway on the right after entering the College, the visitor sees the entrance

of the new large museum across the old hall, now much enlarged by the removal of the room formerly used by the conservator of the museum. This new large museum is a very spacious room, lighted from above and at the north end, and well designed for the exhibition of specimens. The ground floor is chiefly devoted to the use of those wishing to study human anatomy, and arranged on tables of special design are the numerous preparations so well known for their excellence (the work of Mr. Pearson), which formerly occupied the ground floor of the western museum. The tables are so arranged that shelves can be drawn out on which the student may place his book so as to be opposite the specimen which he wishes to "read up" and seats are provided. Around the room in glass cases are arranged osteological preparations and part of the large collection of crania in the possession of the College. There are two galleries in this museum, both of which are to be occupied by pathological specimens as they are added. At present there are many important preparations—the overflow of the older rooms. The arrangement when fully carried out will be very satisfactory, for, after entering the first gallery in the old western museum, the preparations can be most usefully studied in a definite order from the left, the series being so arranged that the student passes from group to group in their order and, returning into the old museum, ends the tour of the galleries on this floor at the old entrance. He can then ascend and follow a series in continuation of the other, arranged in a similar manner in the two galleries above. The anthropological series on the ground floor of the larger of the new museums is continued in the glass cases on the ground floor of the smaller and in the wall cases on one side of the western museum. The middle gallery of the small museum is occupied by teratological preparations and the top gallery by the illustrations, by means of photographs and water-colours, of various diseases. The series of invertebrata have been placed in six table cases in the western museum, the four following table cases next in order being used for the specimens illustrating the development of the human skeleton. The cases in which the series of invertebrata have been placed have been relieved and painted in chocolate—a matter which is worthy of mention, as this colour makes the preparations show much more clearly and is less trying to the eyes, and indicates what is evident throughout, that the furnishing of the museums and arrangement of specimens have been carried out under skilled and practical supervision.

## Medical News.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS IN IRELAND: CONJOINT SCHEME.—The following candidates have passed the First Professional Examination:—

J. C. Baskin, J. W. Benson, W. J. Beveridge, G. E. Cairness, D. F. Clarke, H. F. Conyngham, G. Corcoran, W. M. Cummins, G. G. Delap, J. C. Edge, E. A. Fenton, T. Fitzgerald, R. Glynn, E. M. Hamilton, P. P. Harold-Bary, W. J. Healey, C. E. Hodgson, C. E. Horrell, W. E. Jolliffe, W. M. Jones, C. A. Kenny, C. D. Martin, H. B. S. Montgomery, J. Morrissey, J. A. McInn, M. O'Brien, W. H. Odlum, J. J. O'Reilly, T. J. Perkins, T. J. Poirer, F. J. Purcell, A. S. Sampay, E. W. Scully, J. N. Shea, E. W. Siberry, Miss L. F. Strangman, Miss M. S. Strangman, R. H. Walpole, F. C. Wright, and A. H. O. Young.

THE COATBRIDGE MEDICAL FEES CASE.—On the 1st inst. Sheriff Berry issued an interlocutor reversing the decision of Sheriff-Substitute Mair in the case of Dr. Macphail v. the Coatbridge Town Council. The local Police Act constituting Coatbridge into a burgh contains a clause compelling doctors to report all contagious diseases and providing for their being paid 2s. 6d. for each report. A dispute arose between the medical man and the Council as to whether measles and whooping-cough were included; and the Council eventually adopted the Infectious Diseases Notification Act. The medical men maintain, however, that under the local Act they were bound to report and the Council to pay for the reports of these two diseases. Sheriff Mair gave effect to this contention and the Council appealed to Sheriff Berry, who finds that the defenders, the Local Authority of Coatbridge, having adopted the Infectious Diseases (Notification) Act, 1889, and not having taken steps to apply the Act to measles and whooping-cough, are not now liable to pay to the pursuer fees for cases of these diseases reported by him.

**NEW INFIRMARY, LEWISHAM.**—The Bishop of Lichfield performed the ceremony on Saturday of laying the foundation stone of a new infirmary, to be erected by the Lewisham guardians, at an estimated outlay of £60,000.

**SUPERANNUATION ALLOWANCE.**—Mr. George Cheesman, L.R.C.P. Edin., M.R.C.S., lately district medical officer of the Southampton Incorporation, has been granted a superannuation allowance of £132 19s. 8d. per annum.

**GUY'S HOSPITAL MEDICAL SCHOOL.**—The Right Rev. Randal T. Davidson, D.D., Lord Bishop of Rochester, distributed the medals and prizes at Guy's Hospital Medical School on Wednesday last, July 6th. The dean of the school read the report for the past year and a vote of thanks to the Lord Bishop was moved by the treasurer and supported by the senior physician and senior surgeon.

**MEDICAL MAGISTRATES.**—The names of the following gentlemen have been placed on the Commission of the Peace—namely, John Parsons, L.R.C.P., F.R.C.S. Edin., L.F.P.S. Glasg., and George Stringer Pullon, M.D., C.M. Edin., for the Borough of Barnsley, James Thomson William Baird, M.B., C.M. Edin., and Hugh Moss, M.D. St. And., M.R.C.S., for the Borough of Congleton, and James Aitken Myrtle, M.D., C.M. Edin., for the Borough of Harrogate.—John E. Jones, M.D. St. Andrews, M.R.C.S. &c., of Brynffynon, Dolgelly, having, on the recommendation of W. R. M. Wynne, Esq., the Lord-Lieutenant, been placed on the Commission of the Peace for the county of Merioneth, made the usual declaration and subscribed the necessary oaths and qualified as a magistrate for the county at the Trinity quarter sessions held at Dolgelly on June 28th.

**THE SANITARY INSTITUTE.**—The forthcoming annual congress of this institute will be held at Portsmouth, commencing on Monday, Sept. 12th, and continuing throughout the week. The inaugural address of the president and the sectional and general meetings will be held at the Town Hall, but the Health Exhibition will take place in the new drill hall and include sanitary apparatus and appliances in connexion with the congress. The Duke of Connaught and Strathearn has consented to become the patron.

**PRESENTATIONS.**—Dr. Grant of Ellon has been presented by the St. Andrew's Ambulance Classes, Ellon, with a handsome microscope and case.—Mr. Charles Smith, M.R.C.S., of Kinnairdy, Marnoch, has been presented by his friends, on the occasion of his professional jubilee, with an illuminated address and a purse of 292 sovereigns.—Mr. Richard T. Williams, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., who for several years past was assistant to Mr. J. R. James of Cwm Avon, having left that town, has been presented by his friends and well-wishers at Cwm Avon with a well-executed illuminated address and a costly box of surgical instruments.

**SCHOOLS OF SURGERY: ROYAL COLLEGE OF SURGEONS, IRELAND.**—The following prizes have been awarded for the summer session:—Operative Surgery: G. Hamilton, gold medal; O. W. Elsner and T. C. Perry, equal, silver medals. Practical Chemistry: H. E. Bardley, £3 and medal; H. F. Conyngham, £1. Practical Histology: E. A. Meeke, £3 and medal; E. C. Hodgson, £1 and certificate. Materia Medica: E. T. Moore, £3 and medal; E. A. Meeke, £1 and certificate. Pharmacy: R. M. Hamilton, £3 and medal; H. B. Montgomery, £1 and certificate. Medical Jurisprudence: T. T. O'Donnell, £3 and medal; L. F. Corbet, £1 and certificate.

**INTERNATIONAL CONGRESS OF PHYSIOLOGISTS.**—The second International Congress of Physiologists will be held at Liège (Belgium) from the 29th to the 31st of August. An exhibition of physiological apparatus will be arranged. Those taking part in the Congress, the directors of physiological laboratories and makers of instruments, recommended by members of the Congress, will be at liberty to exhibit. The exhibition will be opened two days before the Commencement of the Congress and be closed two days after its conclusion. Professor Fredericq, director of the Physiological Institute of the University of Liège, has kindly offered to place his institute at the service of members desiring to give demonstrations, or to show scientific apparatus. Those intending to be present at the second congress should communicate with Professor Léon Fredericq, Liège or to Mr. C. S. Sherrington, St. Thomas's Hospital, London, before the 1st of August.

**THE DENTAL HOSPITAL OF LONDON.**—The medical staff and Lecturers of this institution have issued cards of invitation to a conversazione, which is to take place on Wednesday, July 13th, at 8 P.M., at the Royal Institute Galleries, Princes Hall, Piccadilly. At 8.30 P.M. there will be a prize distribution by Professor St. George Mivart, F.R.S.

**THE METROPOLITAN HOSPITAL.**—Lord Sandhurst presided at the recent annual dinner in aid of the funds of the above hospital. He defended the conjunction of a provident dispensary and a general hospital, and assured the public that unless they subscribed more liberally to hospitals they would need to apply to the State or to local funds for support.

**NEW COTTAGE HOSPITAL, HORSHAM.**—On Saturday the deeds of this hospital were delivered to the trustees and the building declared opened. It is well situated in the Hurst-road, provides eight beds in three wards, besides three each in the special male and female wards, and has been erected at an outlay of upwards of £1700, the whole of which is covered by subscriptions received and about £200 a annual subscriptions are promised towards its maintenance.

**THE LORD MAYOR AND THE WELSH EISTEDDFOD.** The Lord Mayor of London visited Bridgend on Monday to open the annual Eisteddfod in aid of the Local Cottage Hospital. His Lordship was received by the Eisteddfod Committee and the members of the Local Board at the railway station and presented with an address of welcome; he was afterwards escorted to the Eisteddfod Pavilion by an imposing procession, where he declared the Eisteddfod opened.

Notes, Short Comments & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."

We cannot undertake to return MSS. not used.

CARPENTER AND DUKES DEFENCE FUND.

We are informed that the appeal made in connexion with this fund has not been responded to in so free a manner as could be wished, considering the principle involved. Dr. Carpenter's family have generously declined to take any part of the subscriptions till Dr. Dukes is fully released from his share of the debt. The following additional subscriptions have been received:—

The Croydon Medical Reading Society	£10 0 0	Dr. Beard .. ..	£1 1 0
The Editors of THE LANCET	3 3 0	Dr. Mickle .. ..	1 1 0
		Mr. C. G. Woodd ..	1 1 0

A CORRESPONDENT cautions practitioners in engaging gentlemen to fill the post of locum tenens to first consult the Medical Register or to obtain some proof of their being registered.

Mr. C. F. Beadles.—The paper will appear in an early number.

ROMANCE IN THE PROFESSION.

To the Editors of THE LANCET.

SIRS,—I have chosen the above title for this communication as it certainly is the most romantic event that has occurred in my practice, now extending over thirty years. I must premise by stating that the patient alluded to had, through no fault of his own, failed in business and was utterly unable to cancel his indebtedness to me of a sum amounting to nearly £50.

Last Wednesday evening a lady and gentleman called to see me and on entering my consulting-room I found they were complete strangers. The first sentence of the latter revealed his nationality and it was evident he hailed from America. As near as I can remember the following conversation ensued. "I think, sir," said he, "you attended Mr. — and his family." "That is so," replied I. "Well, sir, I am under considerable obligation to them, as when my wife here, who is a connexion of theirs, was a little girl and left an orphan they were very kind to her for years and I have never forgotten it. Now, the other night, sir, I went there to supper and as I had been out all day I was considerably tired out and in the evening I was resting on the sofa and I have no doubt they thought I was asleep. Well, sir, I heard all their conversation and Miss — was telling my wife of all your attention and kindness to them—how you under Providence had saved her life and what sorrow they felt at not having been able to recompense you. Well, sir, they talked so much about it that before I got off that sofa I said to myself, 'That doctor shall be paid.' Now, sir, would you kindly look at this?" Here my visitor held out a malacca cane, the handle of which was carefully enclosed in a morocco case. On opening it I found the cane had a beautifully carved ivory handle, which was studded with jewels, consisting of small rose diamonds, eighty or ninety in number, worked into fanciful shapes representing small birds, fish, &c., and here and there a ruby, emerald and amethyst. It was a

beautiful piece of art-work and I quite believe it cost, as he said, £50. He told me he had taken it for a debt in the East fifteen years ago. He then went on to say that if I admired it he hoped I would accept it as a recompense for my attendance upon Mr. — and his family. I, of course, expressed my admiration at the good feeling and sympathy called forth by his proposal and was leaving the room to show the cane to my wife when he stopped me, saying, "Doctor, I have another proposition to make to you. I own a number of plots of building land in the most rising city of —, in South America, where I reside, and if you would prefer it I will give you a plot worth £100 now (and if you stick to it it will soon be worth double). You shall have the deeds sent to you and have it properly transferred on my return from my holiday here, and whichever you like to choose, the stick or the land, I shall be pleased to leave to you entirely." My friend kindly left the jewelled cane in my possession until the morning; but considering the number of burglaries going on in the suburban districts I decided on becoming a landed proprietor in the United States.

I am, Sirs, yours faithfully,

London, July 4th, 1892.

LONDONIENSIS.

P.S.—A kind but possibly envious friend has just informed me that an Englishman cannot hold land in America without residing there for three months. If this is so, I shall be pleased to show you the stick some day.

MEDICAL AID ASSOCIATIONS AND FRIENDLY SOCIETIES.

To the Editors of THE LANCET.

SIRS,—Your lay contemporaries, several of them—most notably *The Times*, *City Press*, *Rock*, &c.—have in a very outspoken manner referred to the great injustice done to the profession by hospitals and dispensaries which admit patients to their benefits without any inquiry at all as to the applicant's ability to pay the modest fee which an ordinary general practitioner asks nowadays. If free medical treatment or treatment for 1d. per week is permissible, even though recipients can afford to pay a proper fee, the *City Press* asks why legal advice should not be afforded on the same terms? I have two newspapers—viz., the *Kidderminster Shuttle*, with an account of the "Proceedings of Council versus Medical Aid Officer," and in the conclusion of the report it is mentioned that several of the members of the General Medical Council stated openly that they held "strong private opinion" on these "medical aids." The President asked the counsel who defended Dr. Martin, "How would the members of your (the legal) profession like associations formed for the purpose of obtaining legal advice and assistance on similar terms?" Mr. Corbett (in the absence of Mr. Lawrence) replied: "I am certain of this, sir, that if such an association were formed we [i.e., the Incorporated Law Society] should endeavour to deal with it promptly." This expression of opinion was met with the ejaculation, "Hear, hear!" from the members of the Council. Those associations have no wage limit; they admit anyone, they rob the outside medical men, they build premises and they save money at the expense of the slavish toil of their medical officers. In small towns they do infinitely more harm to the general practitioner than any of the hospitals or provident dispensaries. The General Medical Council is the only body to satisfactorily deal with this question.

I am, Sirs, yours faithfully,

July, 1892.

A. T. H. D.

To the Editors of THE LANCET.

SIRS,—So much has lately been said in disparagement of Medical Aid Associations that I should feel obliged by your allowing me, as medical officer to one of these associations, to place before your readers the other side of the question.

I fail to see the difference between the working of these associations and that of the club practices of medical men throughout the kingdom. It can only be a question of larger number, the fees paid by members being in both cases identical; and I think I may safely say that, as medical officers to associations, in the majority of cases, do not entertain private practice, they devote more time to their club patients than private practitioners are able to do. And this was a powerful incentive to the starting of Medical Aid Associations; and as to medical men holding these appointments, to my mind it is far better than accepting an assistantcy at an absurdly low salary, or opening a dispensary in the slums and giving advice and medicine for sixpence and sometimes less. Unfortunately, in our profession the supply is greater than the demand, and we cannot therefore choose for ourselves, especially when one is without sufficient capital to embark in private practice in a good way. In your issue of June 18th a question was asked by "A Hospital Surgeon" relative to Medical Aid Associations appointing unqualified assistants. Very few associations provide unqualified men, and the tendency now is to substitute qualified assistants for them; but how do we differ in this respect from private practitioners? Apologising for the length of this letter,

I am, Sirs, yours faithfully,

June 21st, 1892.

"AUDI ALTERAM PARTEM."

To the Editors of THE LANCET.

SIRS,—I hear of a patient lying ill not far from me who is attended by a club doctor, but waited upon by a trained hospital nurse. We move so quickly nowadays that I daresay in a year or two this will be the usual state of things, now that bishops and ex-ministers are so eager to join the nearest friendly society.—I am, Sirs, yours truly,

July 4th, 1892.

M.B.

## THE LEEDS INFIRMARY.

A CORRESPONDENT signing himself "Chapeltown" complains of the 'wrong uses the infirmary is put to. A new wing has been opened, and, as the writer says, "the hat is being sent round" for £5000 a year additional to maintain its efficiency. He objects to the abuse of the out-patient department—to boards of guardians compounding with the infirmary for the treatment of fractures, dislocations, &c., for payment of which the law has already provided as "extras" to the medical officers; to the infirmary continuing the after-treatment of cases taken there in the first instance as emergencies; to employers of labour sending their workmen there for small injuries &c. We are too familiar with such complaints, which are reasonable, and which tend very much to damp true charity for fitting cases.

*Kappa*.—We recommend our correspondent to purchase either Fry's or Lowe's "London Charities," which will give him all the information he requires.

*Justitia*.—Such a certificate should have been submitted to the coroner.

*Medicus* is thanked for his communication.

## FIFTY-THREE MARBLES SWALLOWED AND EVACUATED WITHOUT INCONVENIENCE.

To the Editors of THE LANCET.

SIRS,—J. K. M.—, a boy of sixteen, was admitted on Nov. 10th, 1891, into the Cardiff Infirmary, under Dr. Wallace, on account of, as he stated, having swallowed fifty-three marbles, which he could not get rid of. My thanks are due to Dr. Wallace for his kindness in allowing me to publish this, I believe, unique case. The boy informed me that he had with former experiments on himself swallowed as many as twenty-three marbles and brought them up again without missing one of them. The reason why he took this extraordinary number was that he had suffered on the date of admission heavy losses at a very exciting game of marbles with a friend and with a view to recover his lost property he bet his more skilled (in marble playing) adversary that he would swallow fifty "alleys." The patient won his bet, but was unable to resume the play on account of his inability to reproduce his "commonsens" and "taws." On admission there was a distinct fulness in the epigastrium, which felt, as Mr. Morland, the present house surgeon, remarked, like a thick bag full of small cobbles. On inverting and shaking the boy the rattling as of a receding wave on a pebbly beach could be heard for yards around. The only allusion to a similar phenomenon that I know of is in the celebrated case related to Mr. Pickwick by Mr. Hopkins of St. Bartholomew's Hospital, where twenty-five beads in a child's stomach made "a devil of a noise, like a small hail-storm." On Nov. 11th the patient passed seventeen marbles per anum at 8.30 A.M., and at 7 P.M. on the same day he passed twenty-nine. The remaining marbles were passed next day and the patient was discharged. The marbles weighed ten ounces, and consisted mostly of "commonsens" and a few "top" or "bottle alleys" and two "bloods." A small boy in one of the narrow streets near Drury-lane Theatre informed me that one of the "alleys" was what was called a "buck"—a species of great value on account of being very hard and rebounding well. It is interesting to note that the first batch of seventeen was passed with hardly any feces within twenty hours of being swallowed and they must have passed through the ileo-caecal valve in single file; for several of the marbles were three-quarters of an inch in diameter, the whole number forming a single column thirty-five inches long. In the museum of the Royal College of Surgeons there are many articles reminding one of an ironmonger's shop, but which were got from the bodies of either insane or hysterical individuals and the motive in all these cases was very different from that which prompted the subject of this case to swallow his marbles. I am, Sirs, yours faithfully,

J. THOMAS,  
Late House-Surgeon to the Cardiff Infirmary.

## HOSPITAL FOR THE PARALYSED AND EPILEPTIC.

*Erratum*—On page 47 of our last issue, owing to an obvious error in the transcription of the notes of our report, Sir James Paget was made to say: "It would be a great happiness to him if he could help the progress of the Hospital by speaking of the great good which he had accomplished." The passage should of course have read, "the great good which it [i.e., the hospital] had accomplished."

A.—We cannot defend C.'s conduct supposing it to be as represented. Consultants should set an example of professional propriety.

*Verax* does not give any address.

## THE M.D. WASHINGTON.

To the Editors of THE LANCET.

SIRS,—A young medical friend has asked me to make inquiries regarding the Washington M.D.—how it is obtained, if a previous university training is required, an examination held, and what are the fees. Several practitioners in his neighbourhood have lately called themselves "Doctor" and looking up the Medical Directory he found that this newly acquired distinction was the Washington M.D.

I am, Sirs, yours truly,  
AN ENQUIRER.

July 3rd, 1892.

## ADVERTISING IN VICTORIA, BRITISH COLUMBIA.

THE following is a batch of advertisements from the *Victoria Daily Times*. We trust that public professional opinion will take note of this style by way of caution:—

"Dr. Hugh Watt, M.C.P.S.Ont., and B.C. Late of Cariboo. Office and residence No. 303, Douglas-street (Dr. Milne's old residence)."

"Dr. G. L. Milne. Office—30, Douglas-street. Telephone at office, No. 10. Telephone at residence, No. 208."

"Dr. Sproule, B.A. Dublin University. Surgeon and Physician. Allopath and Homœopath. Late Surgeon British Royal Mail Steamers. Electricity used when suitable. Rooms 1, 3 and 4, Clarence Hotel, Victoria."

"Dr. Ernest Hall, L.R.C.P. and C.M. Edin. Specialty—Eye, Ear, Nose and Throat. Jewell Block, corner of Yates and Douglas-streets."

"Drs. Hall and Leitch. Offices: Friar Block, 60, Douglas-street. Dr. F. W. Hall, M.D., C.M.; Dr. H. D. Leitch, M.D., C.M., M.C.P.S.O., F.T.M.S. Specialty—Diseases of Women and Diseases of Rectum. Lately attending Woman's Hospital and Post-Graduate School and Hospital, New York."

"Homœopathy. Dr. John Hall, 98, Yates-street, over Cochrane and Munn's Drug Store. Chronic and Children's Diseases a specialty. Office hours from 1 to P.M. only, excepting Sunday and holidays."

*Surgeon-Major Naismith, M.D., Ayr*, is thanked for his communication, but we regret that it is too long and technical for insertion in our pages.

*Athenæum* should forward an application to the Lord-Lieutenant of the county for the purpose in question.

*Mr. C. Elliot*.—No.

## THE OPIUM HABIT.

To the Editors of THE LANCET.

SIRS,—A medical man takes a practise in a small country village and finds opium taking extensively practised. The drug, both solid and as laudanum, is apparently sold *ad lib.* by the village chemist to anyone who asks for it. Is the medical practitioner justified in doing nothing, notwithstanding that he has several patients suffering from the effects of opium taking, who are anxious to get rid of the habit and probably would do so if the temptation did not lie at their door? And supposing a death certificate to be signed as due to opium eating, would there necessarily be an inquest? I enclose my card.

I am, Sirs, yours faithfully,

July 4th, 1892.

OPIUM.

## THE VILLAGE NURSE.

To the Editors of THE LANCET.

SIRS,—I should be very glad if any of your readers having experience in such matters would kindly give me hints as to the best method of instituting a "village nurse," one to attend the sick of all classes in a country village; whether it is better to obtain the nurse by advertisement or from a nursing institute. And, also, if there exists any society which assists in providing village nurses.

I am, Sirs, yours faithfully,

July 5th, 1892.

RUSTICUS.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Messrs. Allen and Hanburys, London; Dr. Ascham; Messrs. Arnold and Son; Mr. Baines, Birkdale; Mr. Baird, London; Messrs. The Croonian Lectures

ON THE

CHEMISTRY AND THERAPEUTICS OF URIC-ACID GRAVEL AND GOUT.

Delivered before the Royal College of Physicians of London,

By SIR WM. ROBERTS, M.D. LOND., F.R.S.

LECTURE IV.

CHEMISTRY OF URATIC PRECIPITATION CONTINUED.—BEARING OF THE INVESTIGATION ON THE THERAPEUTICS OF GOUT.

*Topography of Uratic Deposits.*—The topographical distribution of uratic deposits through the various organs and tissues of the body exhibits certain well-marked characteristics. These deposits are found almost exclusively in structures belonging to the connective-tissue class—in cartilages, ligaments, tendons, and other fibrous structures, and in the cutaneous and subcutaneous connective tissues. On the other hand, uratic deposits are conspicuously absent from the muscular tissue, and from the substance of the brain, liver, spleen, and lungs. The tissues which are liable to uratic precipitations are, however, not equally so in the different parts of the body. The cartilages, ligaments and tendons in and about the joints which are bathed with synovia are much more obnoxious to these deposits than are cartilages and fibrous structures situated at a distance from joints and which are not bathed with synovial fluid. It is further to be noted that uratic deposits favour the more superficial and cooler parts of the body, especially the upper and lower extremities, and are more rare in the deeper and warmer interior parts of the trunk. It may be inferred from these particulars that the influences which coöperate to determine the site of uratic precipitations are of several and quite different kinds. I do not propose to discuss this subject comprehensively, but to refer only to two points which seem capable of a chemical or physical elucidation. These are the influence of the proportion of sodium salts in the several organs and tissues and the influence of synovia.

1. *Influence of the Proportion of Sodium Salts.*—We have seen that the dominant factors in uratic precipitation, as studied in the laboratory, are the proportion of urates and the proportion of sodium salts contained in the medium.<sup>1</sup> The highest tendency to precipitation is reached when there is a concurrence of these two factors in maximum intensity. A medium may be rich in urates, but if it be at the same time poor in sodium salts its tendency to precipitation is very feeble, and *vice versa*. This fact has a direct bearing on the topography of uratic deposits. For supposing the system of a gouty man, on the eve of an outbreak, to be throughout equally impregnated with urates, it is obvious from the experimental evidence before adduced that uratic precipitation would take place earliest and most copiously in those parts which were richest in sodium salts, and take place latest or not at all in those parts which were poorest in sodium salts. Let us now examine the distribution of sodium salts in the body and seek to ascertain if there be any correspondence between the liability to uratic deposits in the several tissues and organs and the proportion of sodium salts contained in them. In the subjoined table I have arranged the results of analysis on this point. The materials available for comparison are not so full and precise as could be desired, but their general significance is, I think, quite unmistakable. In order to render the comparison more complete and instructive I have included in the table not only the results with respect to the solid organs and tissues, but also those with respect to blood-serum and its derivatives—lymph and synovium.

TABLE XVIII.—Showing the Percentage of Sodium Salts in the several Fluids, Tissues and Organs of the Body.\*

Blood-serum..	..	..	0.70 per cent.
Lymph ..	..	..	0.80 "
Synovia ..	..	..	0.80 "
Cartilage ..	..	..	0.90 "
Fibrous tissue ..	..	..	0.70 "
Blood-corpuscles ..	..	..	0.20 "
Brain ..	..	..	0.20 "
Muscle ..	..	..	0.08 "
Spleen..	..	..	0.04 "
Liver ..	..	..	0.02 "

\* The figures in this table are to be taken as approximate numbers. Most of them are deduced from analyses cited in Gamgee's "Physiological Chemistry." The figures for synovia and fibrous tissue are deduced from the author's own analyses of the synovial fluid and tendons of the ox, the amounts being reckoned as chlorides. A more recent analysis of human lymph by Munk and Rosenstein (Maly's Jahresbericht, Band xx., p. 40) gives the sodium salts as 0.80 per cent.

An inspection of the table shows that the tissues which are liable to uratic deposits are very much richer in sodium salts than the tissues and organs which are not thus liable. The remarkable immunity from uratic deposits enjoyed by the muscular tissue, by the brain, liver and spleen, may be inferred to be due, for the greater part at least, to their poverty in sodium salts. Turning to Table XIII., we see that the solvent power of a medium for sodium bi-urate increases in correspondence with its lessening proportion of sodium salts. Brain has only about one-fourth the percentage of these salts as compared with cartilage and fibrous tissue, and muscle only one-tenth. This difference signifies (roughly) that brain has four times more power and muscle ten times more power of dissolving sodium bi-urate than cartilage and fibrous tissue; and therefore, respectively, four and ten times more power of resisting its precipitation in their substance. It might probably be truthfully said, on this ground, that brain, muscle, liver and spleen could not become the sites of uratic deposits until the connective tissues had been in this respect exhausted. It is true that the immune tissues and organs have a quicker circulation than cartilages and tendons, and this doubtless contributes importantly to the difference, but it scarcely fully accounts for it, otherwise we should expect that the skin, which is abundantly supplied with bloodvessels, would share this immunity. The prepotency of the cartilages and fibrous tissues to induce uratic precipitation must obviously operate in a conservative direction and serve to protect the more vital organs of the gouty from similar precipitations, where they would produce more deadly effects.

2. *Influence of Synovia.*—The connexion between synovia and gouty deposits is evidently very close and special. Synovial fluid has itself been repeatedly found heavily laden with crystals of sodium bi-urate. In the great majority of the less severe cases of gout the deposits are exclusively confined to those cartilages, ligaments and tendons which are in actual contact with synovial sacs or synovial sheaths. With regard to the articular cartilages it may, I think, be demonstrated that the uratic precipitation actually takes place from the synovial fluid and is not self-originating in the cartilaginous substance. Vertical sections of gouty cartilages are very convincing on this point. If such sections are examined under the microscope, it is seen that the deposit hugs the synovial surface of the cartilage and that it becomes progressively sparser and sparser towards the deeper layers, the central and deepest parts being usually quite free from deposit. This mode of distribution moreover implies that the process of deposition, so far as concerns the cartilage, is a purely passive one and is no wise active and vital in its initiation. We may suppose that the urate dissolved in the synovia penetrates by liquid diffusion into the superficial layer of the underlying cartilage and that when the critical moment arrives precipitation takes place simultaneously in the synovia and in the cartilage. On this view the after consequences are entirely secondary and are due to the reaction of the tissue against the presence of a foreign body lodged in its substance. It may interest you to know that this process can be artificially imitated in the laboratory and that a counterfeit gouty joint can be produced in the articulations of a dead animal. I here show you samples of such counterfeits. They were prepared in the following manner. Tarsal bones of a pig were suspended in wide-mouthed phials charged with a saturated solution of sodium bi-urate made in hot water and then cooled. The phials were chloroformed, corked and placed in the warm chamber or at the temperature of the room. Re-precipitation of the bi-urate takes place in two or three days. If the bones are now

<sup>1</sup> The proportion of calcium and magnesium salts is always too small to have any appreciable influence on the occurrence of uratic precipitation.  
No. 3594.

examined, the articulating ends are found to be encrusted with a chalky matter, which cannot be wiped off with a towel or removed with a nail-brush. They present an exquisite imitation of the plastered appearance of a gouty cartilage. If vertical sections of such cartilages (previously hardened in absolute alcohol) are made and examined with the microscope, the deposit is seen to be situated in the substance of the tissue, close beneath the synovial surface of the cartilage and to be composed of a dense felt of fine needles of bi-urate. The deeper layers of the cartilage are not affected. It may be inferred that the deposits which occur in the ligamentous and tendinous structures of gouty joints are produced in the same way as those found in the cartilages, and that the precipitation takes place, chiefly at least, from the synovial fluid bathing them, and that they are not due to primary morbid changes in the structures.

Two questions may now be asked: First, Why does gouty precipitation take place preferentially in synovia rather than in its cognates, the serum of blood and lymph? Secondly, why do the joints differ so much from each other in their liability to attack? I will discuss the two questions together, as the arguments often dovetail into each other. It may be that there is, as Sir A. Garrod suggests, some special attraction in the joints for uric acid. There are, however, other factors which come into play. Synovia is a comparatively motionless fluid, while serum and lymph are in ceaseless motion. As a still pool crystallises into ice sooner than a running brook, so likewise, supposing serum, lymph and synovia to be equally impregnated with urates and sodium salts, the tranquillity prevailing within the synovial cysts would give to synovia a priority in uratic precipitation over the restless blood-serum and lymph. Then as regards the varying liability of the different joints to gouty attacks, it may be pointed out that the synovial pouches and sheaths are shut sacs, standing apart from each other and isolated from the general panmixia of the circulation. It might consequently be expected—indeed it is an observed fact—that the synovial fluids in different joints should present differences in the relative proportion of their constituents. Some are certainly more concentrated than others; and we can easily believe that they are not quite identical in their degree of impregnation with urates and with sodium salts. In this way the several joints might come to vary considerably in their liability to uratic precipitation.

Frichs<sup>2</sup> has contributed some interesting particulars on synovia in animals. His observations indicate that synovia varies both in quantity and quality under different modes of life. He found that stall-fed horses and oxen, leading an idle existence, had twice as much synovia in their joints as similar animals roaming in the meadows or doing work. Moreover the composition of the fluid varied in the two cases. In the idle animals the synovia was more watery and contained less albuminoid matters but, and this is significant, a larger proportion of mineral salts, which consist almost entirely of sodium salts. We might conjecture from this fact that if horses and oxen were liable to uratic precipitations the idle stall-fed animals would be more subject to such deposits than the same animals leading a more active life. Perhaps we may discern herein one reason why men who lead a sedentary life are more subject to gouty deposits than men who take active exercise.

*Interpretation of the Appearances found at the Necropsy of Gouty Subjects; Re-solution of Gouty Deposits.*—Before leaving the subject of the topographical distribution of gouty deposits I should like to say a word on the need of caution in interpreting the appearances, both positive and negative, observed at the necropsy of gouty subjects. The incidents of the gouty diathesis, especially in the early periods, pursue a markedly interrupted course. Long intervals of months or years often elapse between the arthritic outbreaks. During these intervals the blood of the gouty recovers its purity more or less completely and approximates in its content of uric acid to the blood of a healthy person. The solvent relation of the bodily fluids to the material of uratic deposits is simply a question of saturation and subsaturation. If the lymph or synovia at a certain spot becomes saturated, or rather supersaturated, with sodium bi-urate, precipitation of that substance will inevitably take place into the contiguous fibrous tissues. And if after such an event the lymph or synovia recovers its purity and becomes approximately free from bi-urate, as in

due course usually comes about, a process of slow resolution will of necessity set in. For, as has been before demonstrated, sodium bi-urate, although very sparingly soluble, is by no means insoluble in these media. The rate and amount of re-solution of uratic deposits must necessarily vary greatly in different cases, according to the degree of subsaturation attained by the bodily fluids, the massiveness and penetrability of the deposits, and the length of time during which the favourable conditions endure.

If regard be had to the often long survivorship of gouty persons and the interrupted course of the arthritic incidents, it seems highly probable, in the lapse of a long life, that deposition and re-solution of uratic matter may take place once and again in a gouty joint. There are undoubted instances, of which Sir Dyce Duckworth<sup>3</sup> records one observed by himself, where no uratic concretions have been found after death in joints which had at some previous period undergone typical gouty attacks. The presumption in such a case is, not that deposits never existed, but that they had been redissolved in the intervals of amendment. Uratic concretions in the pinna of the ear have sometimes been actually observed to come and go and come again. There is no reason why the same thing should not occur within the joints, and such vanished concretions might leave behind them permanent changes in the cartilages and bony structures as tell-tale evidence of their former presence. On the other hand, the discovery after death of uratic deposits in a joint is not always to be regarded as a certain proof that the joint had passed through an inflammatory gouty attack. The observations of Moxon and Fagge seem to warrant this conclusion, and they reasonably suggest that when the precipitation of the urates takes place slowly and by degrees there may be no accompanying inflammatory outbreak to mark the event.<sup>4</sup> The experimental evidence before adduced indicates that when lymph or synovia is impregnated with sodium bi-urate to or above 1 part in 6000 the medium is supersaturated and precipitation either actually occurs or is impending. On the other hand, when these fluids contain less bi-urate than 1 part in 10,000 the medium is under-saturated and there resides in it a certain power of redissolving uratic deposits, and of course the nearer the medium is to freedom from urates the higher rises this solvent power. It may further be inferred that the solvent action will be most effective in the case of deposits situated in textures like the fibrous tissues, which have a comparatively free lymph flow, and conversely that it will be least effective in textures like the cartilages, which have a sluggish lymph flow. This is probably the reason, or chief reason, why the cartilages figure more prominently than the fibrous structures in the morbid anatomy of old gouty joints. Probably both tissues were originally infiltrated with bi-urate crystals in equal degrees; but the fibrous structures afford greater facilities for their re-solution in the periods of amendment than the cartilages, and hence the greater persistence of the deposits in the latter tissues.

*The Mode in which Uric Acid produces its Injurious Effects.*—A problem of great interest in regard to the elucidation of gouty manifestations is the mode or modes in which uric acid produces its injurious effects. The main question is whether these effects are exclusively due to the *mechanical damage* consequent on its precipitation as sodium bi-urate in the tissues, or whether, in addition, uric acid circulating in the blood in a state of solution is capable of acting as a *true poison*. With regard to the incidents of regular gout the mechanical theory seems to offer a natural and complete explanation. The crystalline urates precipitated in the cartilaginous and fibrous structures of the joints necessarily act as foreign bodies; they excite irritation, clog the lymph channels, exercise pressure on the tissue elements and impede their nutritive operations. These effects sufficiently account for the inflammation, pain and swelling which ensue, and explain the remoter degenerative changes which follow after. Nor need we look beyond physical conditions to account for the diversity witnessed in the local manifestations. It is easy to understand that depositions occurring within the tense unyielding structures of the joints would produce widely different results from similar depositions in the loose subcutaneous tissue or in the rim of the ear. It is equally easy to understand that the suddenness or slowness of the precipitation, its copiousness or scantiness, would necessarily cause great variation in the intensity and character of the

<sup>3</sup> Treatise on Gout, p. 68.

<sup>4</sup> Fagge and Pye-Smith's Handbook of Medicine, p. 674.

<sup>2</sup> R. Wagner's Handwörterbuch d. Physiol., Bd. iii., pt. 1, p. 403

local disturbances. So easy and natural is this explanation that we might even predicate, from our general knowledge of pathological cause and effect, that if similar depositions of crystals of carbonate of lime, or of any other inert substance, were to take place in the same localities there would follow very much the same train of morbid sequences as are witnessed in connexion with uratic precipitations. It is in the explanation of the phenomena of irregular gout that the mechanical theory of the action of uric acid seems inadequate, and it is to meet this lack that the theory of a poisonous action has been set up and is invoked. The visceral disturbances and manifold neuræses which trouble the gouty have not yet been anatomically traced to uratic precipitation, and there seemed no other way of explaining their occurrence, if they were to be linked with uric acid at all, except by assuming that uric acid was possessed of toxic properties.

The acceptance of this view appears to me on several grounds to be extremely difficult. There is, first, the complete absence of direct experimental proof. Animals have been made to ingest large quantities of uric acid with their food, and urates in solution have been freely injected into their veins without eliciting any signs of poisoning. In the next place, the idea that uric acid is poisonous seems opposed to broad biological analogies. Uric acid is the physiological homologue of urea; each of these bodies constitutes in its separate domain the final term of nitrogenous metabolism. Now, it cannot be said, without an abuse of terms, that urea is a poisonous substance,<sup>5</sup> and it would be strange if its homologue, uric acid, differed from it in so important a particular as the possession of toxic properties. The theory appears not less improbable when examined from a nearer point of view. The system of the gouty man is at times surcharged with uric acid. On the eve of an outbreak the fluids of his body, in parts at least, must be impregnated with bi-urate to saturation; for of course no precipitation can occur until this point is reached. Yet with fluids saturated with urates such persons often betray not the slightest sign of poisoning and enjoy complete immunity from symptoms of every kind until overtaken unwarned by the sudden precipitation which provokes the arthritic attack. Again, the manifestations of irregular gout are so extremely diverse in seat and character that it is hard to believe that they can be produced by one and the same toxic agent. Sometimes they implicate the stomach, sometimes the liver or heart or lungs and oftenest of all the nervous system. This diversity is, however, easily explicable on the supposition that the disturbances are not caused by uric acid in a state of solution acting as a poison, but are really due to actual precipitation of crystals of bi-urate into the connective and fibrous structures of the implicated organs or into the fibrous sheaths of the nerves which control their functions. Observations at the bedside and in the dead-room lead to the inference that uratic precipitation is very variable in its mode of incidence. In certain conditions the crystals descend in sudden and copious showers, which provoke a sharp inflammatory reaction, as in the regular arthritic seizures. In other conditions the crystals fall in gentle sprinklings, sufficient perhaps to excite irritation if the implicated tissue be a sensitive one, but not enough to cause downright inflammation. The peculiar pricking pains in the joints which some gouty persons invariably experience after partaking of certain wines are highly suggestive of the occurrence of these slighter precipitations. Now if these slighter precipitations instead of falling on the joints fell upon the membranes of the brain or upon the fibrous sheaths of the nerve roots this would, I submit, afford an adequate explanation of the phenomena of irregular gout. Of course it may be objected that no such slight precipitations have actually been found. But have they been looked for? Has the microscope been used in the investigation? In prosecuting such a search it would have to be borne in mind that such precipitations would be apt to be fugitive, and that negative results would have to be interpreted with caution. For it is obvious, in the case supposed, that when the

stress of saturation of the fluids with urates was relaxed and the blood again recovered its power of dissolving these compounds these slight deposits would be speedily removed by re-solution, and not a trace of them might remain at the necropsy. We scarcely realise how imminent a slight but widespread precipitation of the crystalline bi-urate must not unfrequently be in the gouty system. It was shown in the preceding lecture that when the serum of the blood is impregnated with sodium bi-urate to the extent of 1 part in 6000 supersaturation is attained and precipitation is then, of course, imminent. It was also pointed out that Sir A. Garrod had proved by quantitative analysis that the blood-serum of the gouty man is sometimes actually impregnated with uric acid to this extent. These two facts taken together indicate that the explanation here suggested of the phenomena of irregular gout stands on a strong basis of *a priori* probability and thus dispenses with the necessity of assuming that uric acid and its compounds are endowed with poisonous qualities. This mode of viewing the subject enables us to bring the diverse morbid effects of uric acid into uniform line. Uric acid and its compounds are deleterious simply because of their sparing solubility in the bodily media. It may be said that the final cause of uric-acid gravel is the sparing solubility of free uric acid in urine, and in like manner it may be said that the final cause of gouty precipitations is the sparing solubility of sodium bi-urate in blood-serum, lymph and synovia.

#### BEARINGS OF THE INVESTIGATION ON THE THERAPEUTICS OF GOUT.

In dealing with the therapeutics of gout I shall confine myself to those points which have a chemical bearing and which can be brought into touch with the results of the foregoing investigation. According to the views developed in these lectures the mischief done by uric acid in gout is contingent on its precipitation as crystalline bi-urate in the tissues or in the fluids of the body. Within this limited scope the study of the treatment of gout resolves itself into a study of the means we possess of controlling the factors which promote or hinder this precipitation. These means may be divided into those which belong to the domain of diet and regimen and those which consist in the administration of medicinal substances.

##### I. DIET AND REGIMEN.

*Restricting the production of Uric Acid.*—It has been shown that one of the main factors in determining uratic precipitation is the percentage of urates in the medium. Other things being equal the larger the proportion of urates presents the earlier and more abundant is the deposition of the crystalline bi-urate. Our power of controlling this factor lies almost entirely in the direction of regulating the diet. Numerous series of experiments have been made on the effect of diverse kinds of food on the production and excretion of uric acid. The chief point of therapeutical interest that has been clearly made out is this, that the ingestion of large quantities of proteid matter is attended with an increased production of uric acid and *vice versa*. It does not appear clear that proteid substances derived from the animal kingdom differ in this respect from those derived from the vegetable kingdom. But inasmuch as the commonly used articles of food of animal origin—such as butcher's meat, poultry, game, fish, eggs and cheese—are richer in proteid stuff than the commonly used articles of vegetable origin—such as bread, oatmeal, rice, potatoes and garden products—it is true that a vegetable diet is less productive of uric acid than an animal diet. The most trustworthy experiments indicate that fat, starch and sugar have not the least direct influence on the production of uric acid; but, as the free consumption of these articles naturally operates to restrict the intake of nitrogenous food their use has indirectly the effect of diminishing the average production of uric acid. There may be, and indeed undoubtedly are, other differences between animal and vegetable articles of food, and between one article and another of the same class, which are highly important. They differ considerably among themselves in their digestibility and in their stimulating qualities, but in regard to the point under review—namely, their direct influence on the production of uric acid—articles of diet must, as far as our present knowledge goes, be classified according to the percentage of albuminoid matters contained in them. As a rough guide in the choice of food for the gouty the subjoined table may prove useful.

<sup>5</sup> The word poisonous is here used with its ordinary meaning. Almost any substance which could be got into solution in the blood in very large quantities would produce deleterious effects—even common salt. Urea can be taken into the stomach in drachm doses without harm, and Dr. Ross Bradford, who has paid particular attention to this point, informs me that the human body contains habitually in the normal state some thirty to forty-five grains of urea, and may contain very much larger quantities than this without provoking any signs of poisoning.

TABLE XIX.—Showing the Average Percentage of Albuminoid Matters contained in Diverse Articles of Food.

Animal food :	Albuminoid matter.
Butcher's meat .. .. .	19 per cent.
Fowl .. .. .	20 "
Game .. .. .	22 "
Fish .. .. .	17 "
Egg .. .. .	13 "
Milk .. .. .	4 "
Cheese .. .. .	30 "
Vegetable food :	
Bread .. .. .	8 "
Oatmeal .. .. .	12 "
Rice .. .. .	6 "
Green peas .. .. .	6 "
Potatoes .. .. .	2 "
Carrots and turnips .. .. .	1 to 2 "
Green vegetables and salads .. .. .	1 to 2 "
Fresh fruit (excluding nuts) .. .. .	0.5 to 1 "

In choosing a diet for persons who are disposed to uratic precipitations regard must of course be had to the whole condition, and especially to peculiarities of the individual. Nowhere perhaps is it more necessary than in gout to consider the man as well as the ailment, and very often more the man than the ailment, but the general rule in reference to the point under notice is, I think, pretty clear. Gouty people should be advised to partake cautiously of butcher's meat, fowl, game and cheese, and to partake as freely as their digestion will permit of bread, rice, garden vegetables, salads, and fruit. The advantage to be gained from an adjustment of the dietary on these lines may be inconsiderable or even inappreciable in cases of inveterate gout, but it may be of critical moment in the slighter cases. A diminution of one or two grains a day in the amount of uric acid thrown into the circulation may make all the difference between the occurrence or non-occurrence of an arthritic attack.

The use of alcoholic beverages, as constituting an important feature in our dietetic habits, may here claim a word of comment. The most reliable researches indicate that these beverages in their legitimate use exercise no appreciable influence either way on the quantity of uric acid produced in the body. It was, moreover, found in my laboratory experiments that the addition to the medium of small quantities, such as might conceivably reach the circulation, of spirits, wines, or malt liquors had not the slightest effect on the solubility of sodium bi-urate, or any influence in accelerating or retarding the precipitation of the bi-urate in blood-serum impregnated with uric acid. The special and highly important part played by certain classes of alcoholic beverages in fostering a proclivity to uratic depositions is evidently of a very subtle and complex character, and has apparently no direct reference to the chemical problems discussed in these lectures.

*The Use of Culinary Salt.*—It was shown in the preceding lecture that the solubility of sodium bi-urate was conspicuously influenced by the proportion of sodium salts in the medium. I observed, moreover, in my experiments on the maturation of blood-serum impregnated with uric acid that the addition to the medium of small quantities of sodium chloride (0.1 per cent. or even less) always appreciably hastened the precipitation of the crystalline bi-urate. It has also been shown that the topographical distribution of uratic deposits through the body bears a close and striking relation to the percentage of sodium salts contained in the several organs and tissues. Indeed, it might apparently be said with truth that if we possessed the power of regulating the dosage of sodium salts in the fluids and tissues we should be able effectively to control the occurrence of uratic depositions. Our power in this respect is, however, limited. Sodium salts belong to the physiological constants of the blood and their proportion therein can only be modified within a comparatively narrow range. These remarks apply especially to the most abundant of them, the sodium chloride. It has been found in experiments on animals that when common salt is given in excess with the food, or injected into the veins, the surplus is for the most part quickly removed by the kidneys, and there is only a small and transient increase of its percentage in the blood. Conversely, when animals are fed with food abnormally poor in salt there is only a slight falling off in its proportion in the blood, while it almost disappears from the urine. The blood clings with great tenacity to its proper percentage of sodium chloride, and the experimental evidence indicates that in case of a threatened salt famine within the economy the blood has the faculty of supplying its necessities by extracting salt from the less vital

fluids and tissues, and contrariwise, in case of a glut of salt in the blood, the overplus is temporarily passed over into the serous cavities until such time as the kidneys have succeeded in restoring the normal equilibrium.<sup>6</sup> All this leads to the inference that by lessening the intake of salt with the food we should abate its proportion in the blood only to a slight degree, but should diminish its proportion in the synovial fluids and fibrous tissues considerably. Acting on these ideas I have been in the habit for some years past of directing gouty patients to restrict, as far as practicable, the use of common salt with their meals.

II. ADMINISTRATION OF MEDICINAL SUBSTANCES.

In forecasting the possible effects of medicinal substances given internally in the treatment of gout it is well to fully realise the actual conditions of the problem. These are widely different from those presented to us in urinary gravel. In the latter case the daily dose is designed to form an addition to a comparatively small bulk of fluid—namely, to the forty or fifty ounces which constitute the diurnal discharge of urine. In the case of gout we are seeking to make an impression on a much larger bulk of fluid—namely, on the totality of the blood, lymph and synovia—a quantity in a man of average weight certainly not less than twenty pounds. Consequently the effect of our dose must be proportionately less. Moreover, the urine is a dead excretion; it takes and keeps what is cast into it and has no power of self-purification. The blood, on the other hand, is a living stream with high powers of self-adjustment to a normal standard. A practicable dose of an alkaline carbonate enables us to radically alter the urine—to change its reaction from acid to alkaline and thereby to exercise a decisive therapeutical effect in uric-acid gravel; but the same dose only produces a feeble and transient effect on the mass of the blood and lymph. The blood passes on the surplus alkali with all speed through the kidneys into the urine and quickly reattains its proper physiological standard of alkalescence.

The medicinal agents which have been chiefly employed in the treatment of gout with a view of controlling the tendency to uratic precipitation are the carbonates and phosphates of potash and soda, the carbonate of lithia, piperazine and the waters of mineral springs; and it is to these alone that I propose to call attention.

*Alkalies.*—Alkaline substances are largely employed in the treatment of gout, both as pharmaceutical preparations and as components of mineral springs. It is believed that the alkaline carbonates and phosphates administered internally by increasing the alkalescence of the blood enhance its solvent power on the material of gouty deposits and thereby delay or prevent their formation. The experimental evidence laid before you entirely destroys this hypothesis. It has been conclusively proved that alkalescence, as such, has no influence whatever on the solubility of sodium bi-urate. It has, moreover, been shown that the addition of an alkaline carbonate to blood-serum impregnated with uric acid produces no appreciable effect on the process of maturation and the advent of precipitation of the crystalline bi-urate in the medium. The use of alkalies in gout has been advocated on another ground. It is held in a vague sort of way that there is an undue prevalence of acid in the gouty system and that the blood is less alkaline than it should be. In some quarters it is even believed that this is the primary vice of the gouty state, and that there exists a so-called "acid dyscrasia" which dominates the whole condition. I have been at some pains to ascertain what foundation there is for this belief. I have found very little of any kind and none that is really valid. In the numerous examinations of the blood in gouty subjects made by Sir Alfred Garrod the serum was invariably found to be alkaline, never acid or even neutral. He remarks that there is often (not always) a marked alteration in the degree of its alkalinity, and that in cases of chronic gout the serum sometimes shows a near approach to neutrality. It is, however, obvious that observations on the alkalinity of the blood have no validity in regard to the point under consideration unless they are made on cases of gout pure and simple. Gout is often complicated not only with pyrexia but with serious secondary lesions in the kidneys and joints which lead to a profound cachexia. These secondary lesions bring with them blood changes of their own, which are only remotely connected with the primary disorder and have no bearing on the etiology of uratic pre-

<sup>6</sup> Lavage du Sang, by Dastre and Loye, Archives de Physiologie, 1888, p. 63.

precipitation. In the last few years some exact quantitative measurements have been made of the alkalinity of the blood both in health and in disease.<sup>7</sup> These researches indicate that a diminished alkalescence of the blood is a common pathological deviation; and that it occurs in a variety of conditions which have no special relation to gout—namely, in pyrexia, in diabetes, carcinoma, acute rheumatism, anæmia, leukaemia and apparently in every kind of general cachexia. These facts and considerations suffice to show that in the present state of our knowledge the belief in an acid dyscrasia in gout rests on a pure assumption.

*Carbonate of Lithia and Piperazine.*—These two substances have been introduced into the treatment of gout expressly on chemical grounds. Solutions of these substances possess a high solvent capacity for free uric acid; it has been inferred from this fact that their administration internally might exercise a favouring influence on the solubility of sodium bi-urate in the bodily fluids and thereby tend to prevent the formation of uratic depositions. This inference, however, does not appear to be justified. I found experimentally that the addition of carbonate of lithia or piperazine in the proportion of 0.1 per cent. and 0.2 per cent. to blood-serum or synovia had not the slightest effect in enhancing the solvent power of these media on sodium bi-urate, nor the least effect in retarding its precipitation from serum or synovia artificially impregnated with uric acid. If these bodies have any beneficial action in gout, it is, I think, certainly not due, as has been supposed, to their solvent action on the material of gouty concretions.

*Mineral Springs.*—The bearing of the inquiry on the use of mineral waters is, I think, of important practical interest. A considerable number of the springs to which gouty patients resort are strongly impregnated with the salts of soda. Now it has been conclusively shown that all the salts of soda act adversely on the solubility of sodium bi-urate and hasten its precipitation, and it may be inferred that the introduction of these salts into the circulation must tend to favour the occurrence of uratic depositions in the body. It is not therefore surprising to learn that not unfrequently the first effect of these waters on a gouty patient is either to provoke a down-right attack of gout or to aggravate the symptoms under which he was suffering. This event is now recognised by the physicians practising at those spas as a thing to be looked for, and experience has taught them the necessity of caution in regard to the quantity of the waters to be taken by new comers. They comfort themselves and their patients, however, with the belief that this preliminary storm is a necessary prelude to the calm amendment which is to follow. There is no doubt some foundation for this idea. It is no fiction that a gouty man, tormented with symptoms of irregular gout, is relieved by a regular arthritic attack. I presume that this arises from the complete, or approximately complete, precipitation of the urates floating in his blood and lymph into the structures of the joints. The urates are thereby as effectually removed from the vital fluids as if they were eliminated by the kidneys. It must, I think, be allowed that this is a rough mode of cure and that it brings with it serious pains and perils of its own. My impression is that gouty persons should either entirely avoid springs which owe their activity to sodium salts or should use them very sparingly. It is difficult to believe that they can do any direct good and easy to believe that they can do direct harm. If they do any good at all, it must be indirectly, by acting on the liver and the intestinal tract; and we possess other means of effecting this purpose without inducing any collateral risk. There are, however, other springs of high and growing repute in the treatment of gout which are not open to these objections. These springs contain no soda or only traces, and the sum of their mineral constituents does not exceed that which is often present in ordinary potable waters. They contain for their principal ingredient a little carbonate or sulphate of lime and it is very doubtful whether the whole of this is absorbed into the blood. Most of it probably passes out inertly with the feces. In fact, springs of this class may practically be considered as equivalent to ordinary drinking water, except that several of them have the advantage of being thermal. Among springs of this kind may be mentioned in our own country the waters of Buxton, Bath and Strathpeffer; in Germany the waters of Gastein, Wildbad, Pfaffers and the Saucrling spring at Carlsbad; in France the waters of Aix-les-Bains, Contrexéville, Vittel and Barèges.

Now, there can be no reasonable doubt that the efficacy of these springs has nothing to do with their scanty mineral ingredients, but depends on their watery constituent. They are drunk freely and on an empty stomach. Their action would be to temporarily dilute the blood and lower its percentage of urates and sodium salts. This effect would tend to retard or prevent uratic precipitation and thus give the defective kidneys additional time to overtake their arrears in the task of eliminating uric acid.

It may be asked whether the drinking of water at home would not answer as well as resorting to a mineral spring. The inference from my experiments is that, other things being equal, the beneficial results would be the same. But the "other things" never are equal. It would scarcely be practicable for a man going about his usual business to drink eight or ten tumblers of water on an empty stomach every day for two or three weeks. At a watering-place the visitor has nothing to do except to attend to his "cure." Moreover, in getting away from home, he leaves behind him the worries of his daily life, and experiences the advantage of change of air and scene, with a salutary modification of diet, and has abundant leisure for out-door exercise. All these collateral influences help to raise the general level of health and quicken the action of the secretory cells. I do not think, therefore, that we can forego the advantages of the time-honoured practice of a visit to a mineral spring. At the same time, a word may be said in favour of a more systematic use of water in the every-day life of the gouty. I have observed that some gouty persons are very sparing in their use of diluents; such persons should be encouraged to be habitually more liberal in this respect. In a few cases it might even be possible to imitate with plain water the regular two or three weeks' course at the spa, and to repeat this course twice or thrice a year as a prophylactic measure. I may observe that in scarcely any complaint is there more need of caution in judging the effects of remedies than in gout. The incidents of the gouty diathesis exhibit a waviness—a flux and reflux—which is highly characteristic. There is a natural tendency for the periods of aggravation to be followed by periods of amendment, and it requires a good deal of sobriety of mind to avoid being made the dupes of our own preconceptions. I believe that the most promising road to an improved therapeutics of gout lies through a fuller and more accurate knowledge of the chemistry of uric acid and the urates, and a more penetrating study of the reactions of these compounds with the fluids and tissues of the body. This is a large and difficult field of inquiry and demands the coöperation of many labourers. That is my apology for the fragmentary character of the present contribution. I shall, however, be quite satisfied if what I have done prove an incentive and a help to other workers in the same field.

## Clinical Lecture

ON AN

### EXCEPTIONALLY COMPLICATED CASE OF INGUINAL HERNIA, FOR THE RADICAL CURE OF WHICH BASSINI'S OPERATION WAS PERFORMED.

Delivered at the Middlesex Hospital, May, 1891,

BY J. W. HULKE, F.R.C.S. ENG., F.R.S.,  
SENIOR SURGEON TO THE HOSPITAL.

GENTLEMEN,—Some of you have lately seen me perform Bassini's operation for the "radical cure" of an inguinal hernia in a patient in Founder ward. As this method has, so far as my knowledge extends, met with little notice here, and as the form of hernia was exceptional, I have taken this case as the subject of to-day's lecture.

The patient, S. R.—, aged thirty-five years, a porter, a well-grown, muscular man, was sent into the hospital by his doctor on Jan. 3rd last, in the hope that something might be done for the cure of a very large rupture which had latterly become so troublesome as to compel him to give up work and for the restraint of which he had tried several forms of truss, but none could be borne. He said that the rupture

<sup>7</sup> See Peiper in Virchow's Archiv, 1880; and a paper by Rumpf in Centralblatt f. Klin. Med., 1891.

had existed since his childhood, and that its size varied greatly. On stripping him it was at once apparent that the right side of the scrotum was imperfectly developed and that the corresponding testis was absent from it. It was also seen that the right groin was occupied by a conspicuously prominent oblong swelling. The innermost limit of this was slightly to the median side of the spina pubis and the outermost limit was separated by only a slight interval from the anterior superior spinous process of the ilium. This large swelling was in part resonant, showing the presence of intestine; and it also enclosed a soft, solid, pellety mass, plainly omentum. It contained also near its inner end, above and slightly external to the spina pubis, a smooth ovoid body of about the size of a hazel nut, obviously an imperfectly developed testis. We ascertained that this conspicuous swelling, evidently lying superficially in the front of the aponeurotic tendon of the external oblique muscle, was continuous through the external abdominal ring with a deeper swelling, covered by this tendon, filling the inguinal canal; so that the superficial and the deeper parts were loculi of one swelling. Its objective clinical features and its anatomical relations made it evident that this large inguinal swelling was a complete, congenital entero-epiplocele which, in association with imperfect evolution of testis and scrotum, after escaping through the external abdominal ring, had had its downward passage into the scrotum arrested, and had been turned aside in an upward and outward direction along the groin, thus taking approximately the course usually pursued by an enlarging femoral rupture. From this last form of rupture our patient's was immediately distinguished by two ascertained facts: (a) the spot where its most conspicuous part became superficial was the external abdominal ring; (b) it enclosed the testis.

An oblique inguinal hernia of long standing, through yielding of the inter-columnar fibres and wider separation of the pillars of the external ring, giving this opening a long slit-like form, of which the outer end may approach or even transgress the position of the internal ring, may very exceptionally acquire a deceptive appearance of lying in front of the tendinous aponeurosis, and it is conceivable that in this condition it might present a deceptive resemblance to the superficial part of our patient's rupture. Here, however, the ascertained form of the external ring negatived any such illusion. When occurring in association with a testis detained either within the abdomen or in the inguinal canal or just below the external abdominal ring a rupture on escaping through this aperture usually, as noticed already, descends into the scrotum, and it only exceptionally takes the course it pursued in our patient. Still more exceptionally does the rupture enlarge in both directions, as in an instance which some years ago I communicated to the Royal Medical and Chirurgical Society, where, in association with retained testes, on both sides one part of the hernial sac passed downwards into the scrotum, whilst another part of the sac had travelled upwards and outwards upon the aponeurosis of the external oblique muscle nearly to the anterior superior spine of the ilium.

Looking at the subject of hernia from your present standpoint—as students—it will probably astonish most of you to hear that operations for the "radical cure" preceded by several centuries those for the relief of strangulation. The reason of this is not far to seek. In early times, when efficient trusses such as we now have were unknown and the only supports were bags slung by a baldrick across the shoulders, which whilst they in some measure eased the painful dragging of an increasing scrotal rupture did not make any pressure on the abdominal openings through which the viscera escaped from the abdomen, very large ruptures must have then been as common as they are still in countries where surgical culture is yet at a primitive level. But in olden times, when a man was chiefly valued for his "thews and sinews," if he became incapable and he could neither bear arms nor do heavy agricultural work, he was apt to be regarded by his community as a useless encumbrance, and his lot was so sad that he was willing to incur any risk and pain for a prospect of relief, and parents were ready to subject their ruptured children to any travelling charlatan who promised a cure. Strangulation, an incident of relatively infrequent occurrence, was regarded as a desperate disorder beyond help from leechcraft. For our own country this is shown by the "bills of mortality" of old London, in which strangulated hernia is entered under the terribly significant name "Miserere."

So numerous are the surgical methods devised in the last

two decades of this century for the "radical cure" of hernia and so preponderant are the advantages claimed for each by its originator, that the young and as yet inexperienced surgeon may well feel some bewilderment when first he approaches this subject practically. Here a principle laid down by the late Professor John Wood will help to guide his choice—viz., to discard every method which does not aim at closing the neck of the sac and at reducing the internal abdominal ring to the extent sufficient only for the passage of the spermatic cord. Both these desiderata are very certainly effected by Bassini's method, which also strengthens the outer part of the posterior wall of the inguinal canal, where naturally it is weaker; and this it does with, I think, greater precision than is attainable by other methods approximately or strictly subcutaneous. My choice of Bassini's method for this particular case was largely influenced by the fact that we had to deal with a complicated form of hernia, which made preferable a method of operating that permitted each step to be clearly seen and precisely controlled. If you will now follow the extract I am about to read from the dresser's notebook you will be able to realise the successive steps of the operation.

On Jan. 7th, the patient having been anaesthetised, an incision from four inches and a half to five inches long was made parallel to and a short distance above Poupart's ligament, in the longest axis of the superficial part of the rupture, and the tissues were divided down to the sac. This was next detached from the aponeurosis of the external oblique muscle and temporarily placed aside out of the way between a couple of flat, warm, moist sponges. The aponeurotic tendon was then split in the line of the external wound from the external abdominal ring outwards along the whole length of the inguinal canal, so that by separating with retractors the edges of the split the inguinal part of the hernial sac was exposed up to its very neck at the internal abdominal ring. The sac itself was now slit open, the bowel contained in it was reduced, and the omentum, adherent and thickened, having been freed, was tied at the level of the internal ring, then cut through below the ligature and the stump returned into the abdomen. The sac was next carefully completely isolated from the other elements of the cord, tied circularly at its neck and then cut away, a small part of it only being reserved for the construction of a tunica vaginalis by sewing its edges together so as to form a small pouch for the testis. This done, a subcutaneous incision was prolonged from the inner end of the inguinal wound to the bottom of the scrotum so as to make a bed for the testis, which was pushed down into it and fixed there with a stitch. The outer border of the conjoined tendon and the fleshy lower borders of the internal oblique and transverse abdominal muscles were then drawn down and attached to the deep aspect of Poupart's ligament by a series of closely set buried sutures so as to closely embrace the cord at its passage through the internal ring and to cover the stump formed by the circularly tied neck of the sac. Next the edges of the split in the aponeurosis of the external abdominal muscle were sutured together; and lastly the integument incision was similarly closed. It is scarcely necessary to say that throughout the operation and afterwards scrupulous attention to antiseptic was observed. Notwithstanding this, on Jan. 15th (one week after the date of the operation) some tension of the wound was apparent. For this two stitches were cut which allowed a free serous oozing. Four days later suppuration was present. This spread superficially a little way below the groin on to the thigh and above towards the flank, necessitating counter-openings and protracting the patient's recovery so that he did not leave the hospital until April 2nd. For greater security he was recommended to wear a light truss and he was directed to return to the hospital if he felt any inconvenience.

The patient returned in January of this year (1892) to ask if he might safely lay aside the truss. This he was told he might do except when engaged in very laborious work. The scar appeared sound, and it did not show any sign of bulging when he strained or coughed. The testis had not remained in the bottom of the scrotum, but it was well below the external abdominal ring. Here the presence of the large subcutaneous inguinal loculus of the sac, enclosing the testis, which was sessile and not as occasionally suspended by a mesorchium, complicated and protracted the operation, making it more severe than it would have been under ordinary circumstances. Its duration might have been shortened by removing the testis, but this

the patient was unwilling to lose, though a functionally useless organ.

So far as the experience of a single case warrants me in forming an opinion, Bassini's method is more severe than some others, and I am inclined to reserve it for exceptional cases.

## PERFORATION OF THE INTESTINE IN PHTHISIS.

BY W. SOLTAU FENWICK, M.D., M.R.C.P. LOND.,  
PHYSICIAN TO OUT-PATIENTS TO THE EVELINA HOSPITAL FOR SICK CHILDREN,

AND

P. R. DODWELL, M.B. LOND.,  
ASSISTANT RESIDENT MEDICAL OFFICER, HOSPITAL FOR CONSUMPTION, BROMPTON.

ALTHOUGH tuberculous ulceration of the intestine is such a common complication of pulmonary phthisis its various modes of termination appear to have received comparatively little attention. The majority of the standard works on medicine and pathology are content to dismiss the question of perforation with the statement that complete rupture of the intestinal wall is a possible but unusual result of its tuberculous affection, while those that deal with the subject in greater detail differ considerably among themselves, both as to the frequency with which perforation is apt to ensue and the clinical symptoms which are supposed to portray the accident. Wilks and Moxon<sup>1</sup> state that complete perforation is rarely met with and they can record but three instances in point, in one of which the appendix vermiformis was the seat of the lesion. On the other hand, Lebert<sup>2</sup> found that perforation occurred in 3 per cent. and Willigk<sup>3</sup> in 5 per cent. of the cases they had observed, while Leube<sup>4</sup> had noted it but twice among several hundred cases. Habershon<sup>5</sup> found that among 56 cases of acute peritonitis due to perforation of the gut, only 4 resulted from tuberculous ulceration. Grawitz,<sup>6</sup> in his analysis of 867 cases of peritonitis, states that 20, or 2·3 per cent., were the direct consequence of tuberculous disease of the bowel. With regard to the actual results of perforation of the intestine the various authors are at still greater variance. Spillman,<sup>7</sup> in his excellent treatise on gastro-intestinal tuberculosis, records several instances where death had occurred from perforation of a tuberculous ulcer, and, while he infers that local abscess is not an uncommon result of the accident, he asserts that extravasation of the intestinal contents into the general cavity of the peritoneum is excessively rare. Theodore Williams,<sup>8</sup> on the other hand, remarks that acute general peritonitis is the most frequent result of perforation of the intestine occurring in the course of chronic phthisis. Rindfleisch<sup>9</sup> lays special stress upon the frequency with which various portions of the small intestine are apt to ulcerate into one another and to establish irregular channels for the circulation of their contents. According to Orth,<sup>10</sup> the vermiform appendix is a favourite spot for tuberculous disease, and perforation in this position is very liable to be followed by the formation of a local abscess and subsequent fistula. In view of these conflicting statements it appeared to us that a further investigation into the subject might prove of interest and perhaps of some practical value. We have accordingly examined the records of 2000 necropsies on cases of phthisis performed at the Brompton Hospital for Consumption and would here gratefully acknowledge the kindness of the senior medical staff in permitting us thus to utilise the records of their cases.

Tuberculous ulceration of the intestine is rarely met with as a primary disease in adults, although in children it is by no means uncommon. In the great majority of cases the disease is secondary to pulmonary phthisis and the frequency

with which the two conditions are associated has been the subject of some controversy. Louis<sup>11</sup> found evidences of ulceration in about four-fifths of all his cases; Bayle in 67 per cent.;<sup>12</sup> while Lebert<sup>13</sup> states that the intestinal complication existed in 67 per cent. of his cases in Breslau and in only 39 per cent. of those examined by him in Zurich. Willigk<sup>14</sup> found the intestine affected in 49·6 per cent. of his cases, and more recently Eisenhardt<sup>15</sup> discovered a similar lesion in 56·6 per cent. of the cases of phthisis examined at München. Our own conclusions tally closely with those of the two latter observers, since we found the intestine was stated to have been the seat of ulceration 500 times in 883 cases, or in the proportion of 56·6 per cent. From these facts it would appear that while the absolute frequency with which the bowel is diseased in cases of pulmonary phthisis is apt to vary in different countries, as a general rule it can be detected in rather more than one half of the cases. All writers are agreed that the ileum, especially its lower portion, is the region of the gut most frequently attacked by the tuberculous processes and among our 500 cases of ulceration the ileo-cæcal region was found to be affected in 85 per cent.; while in 9·6 per cent. it proved to be the only portion of the intestine which showed any evidence of the disease. From this spot the liability to the tuberculous affection diminishes steadily as we proceed in either direction towards the extremities of the bowel and consequently we find that the duodenum and rectum were never diseased unless the other portions of the tract were already in an advanced state of ulceration. Thus among the cases already alluded to ulceration was noted to have been present in the duodenum in 3·4 per cent., in the jejunum in 28 per cent., in the ascending colon in 51·4 per cent., in the transverse portion in 30·6 per cent., in the descending colon in 21 per cent., in the sigmoid flexure in 13·5 per cent. and in the rectum in 14·1 per cent.

Attention has often been drawn to the fact that the vermiform appendix is peculiarly liable to exhibit patches of superficial ulceration in cases of chronic phthisis. Unfortunately, the cæcal appendage appears to have so frequently escaped examination that we are unable to state from our notes with any degree of certainty the relative frequency with which this portion of the bowel was affected. It is, however, quite an exception to find the appendix free from disease when the ileo-cæcal region is in a state of tuberculous ulceration. In seventeen instances it was expressly stated that the appendix was the only portion of the intestinal tract that showed any evidence of ulceration; and the question naturally arises whether this morbid phenomenon was of a simple or tuberculous nature. In every case the ulceration was multiple, and no concretion was noted to have been present. In two cases of a similar nature which have come under our own observation the superficial character of the disease appeared to denote a catarrhal rather than a specific origin, but on submitting the tissues to microscopic examination all doubt as to the true nature of the disease was set at rest by the discovery of numerous tubercle bacilli. Without wishing to infer that all cases of ulceration of the appendix associated with pulmonary phthisis are necessarily tuberculous in their nature, we would submit that this portion of the bowel, owing to the large quantity of lymphoid tissue in its walls, its abundant blood-supply and the comparative stagnation of its contents, is peculiarly liable to fall a victim to tuberculous infection, and that the subsequent ulceration may closely simulate in its macroscopic appearances the results of simple catarrh.

Among our 2000 necropsies we find twenty-five instances in which perforation of the intestine had occurred as the result of the tuberculous ulceration. These figures would appear to indicate that the accident in question only occurs in about 1·2 per cent. of all cases of phthisis, a result which, although it closely agrees with the statements of Dittrich and Louis, nevertheless falls far short of the estimations made by other observers. But these discrepancies are easily accounted for when an inquiry is made into the exact meaning which various writers have attached to the term "perforation." It is well known that advanced tuberculous ulceration of the intestine is invariably attended by a considerable degree of local peritonitis, and it consequently happens that, owing to the firm adhesions which form round the floor of an ulcer actual perforation may occur without giving rise to fecal extravasation and subsequent peritonitis.

Thus, in a curious case reported by Lepelletier,<sup>16</sup> a perforating ulcer in the ileum had contracted adhesions with an enlarged and caseous mesenteric gland which eventually came to fit like a plug into the aperture in the wall of the bowel. Perforation, therefore, may be of two kinds, partial or complete, the evidences of the former being latent and often difficult to ascertain without a careful search, while the latter attracts attention immediately the abdomen is opened, from the striking evidences of inflammation in the serous membrane. For these reasons it is obvious that those statistics which, like our own, are founded upon the complete form of the disease, do not represent by any means the absolute frequency with which tuberculous ulceration is apt to terminate in perforation of the bowel. At the lowest computation partial or complete perforation probably occurs in 5 per cent. of all cases of chronic phthisis, or, in other words, in 10 per cent. of the cases where ulceration is present. These facts by no means corroborate the statement made in text-books to the effect that typhoid ulceration of the intestine is far more liable to end in perforation than the tuberculous type of the disease. If we believe that every case of typhoid fever is accompanied by an intestinal lesion and that only 10 per cent. of the entire number of deaths are the result of perforation of the bowel, then even allowing the primary disease to be attended by the high mortality of 20 per cent. we find that only 2 per cent. of the cases of typhoid ulceration terminate in perforation, instead of 10 per cent. as in the case of the tuberculous lesion. Perforation may occur in any portion of the intestinal tract and at the outset it would seem probable that that region of the bowel which is most frequently attacked by ulceration would also be most liable to perforation. But a glance at the figures relative to this point will show that the surmise is only partially borne out by fact. It is true that the ileum is the favourite site both for ulceration and rupture; but, on the other hand, the cæcum, which is almost twice as often affected as the jejunum, is much more rarely the seat of perforation than the smaller intestine. Again, tuberculous ulceration is infinitely more common in the ascending colon than in the duodenum; nevertheless we find that while perforation in the former is excessively rare, the same lesion in the latter is attended by more danger to life than in any other spot in the whole digestive tract.

In the following table a contrast is offered between the tendency exhibited by the various portions of the intestinal tract to ulceration and perforation respectively. The first two columns are derived from an analysis of 500 cases of tuberculous disease of the intestine, while the remainder has been compiled from a comparison of the total number of cases of ulceration with the various instances of perforation occurring in the same anatomical region. It will therefore be readily understood that although the first half of the table is fairly accurate the latter half can only convey a general idea, as it cannot lay claim to any great degree of accuracy.

Table to Illustrate the Relative Frequency with which Tuberculous Ulceration and Perforation occur in the Different Regions of the Intestine.

Region.	Percentage of ulceration.	Sole seat of disease.	Percentage of ulceration terminating in perforation.	Percentage of acute peritonitis.	Percentage of fecal abscess.
Duodenum .. ..	3.4	—	10.0	75.0	25.0
Jejunum .. ..	28.0	1.4	0.53	65.0	35.0
Ileum .. ..	60.2	4.4	1.1	70.0	24.0
Ileo-cæcal (last foot of ileum and contiguous portion of cæcum) .. ..	85.0	0.0	—	—	—
Cæcum .. ..	—	—	0.12	17.0	83.0
Appendix .. ..	(50.0)	(3.8)	(0.1)	—	—
Ascending colon ..	51.4	1.8	0.08	—	—
Transverse colon ..	30.6	1.0	—	—	—
Descending colon ..	21.0	—	—	—	—
Sigmoid .. ..	13.5	—	0.37	—	—
Rectum .. ..	14.1	—	0.34	—	—

Of the 25 instances of perforation which occur among our series of post-mortem examinations 15 terminated in acute general peritonitis and the remaining 10 by the formation of a local abscess. Since this number is but small we have collected an additional 28 cases from various sources, making in all a total of 53. These have been divided for the purpose of analysis into two classes, and the general features of the cases at our disposal will be considered under the headings "acute general peritonitis" and "fecal abscess."

1. *Acute Peritonitis.*—This class includes 34 cases, in 28 of which a single ulcer had perforated into the cavity of the peritoneum, while in the remaining 6 a previous lesion had occurred and given rise to a fecal abscess. The average age at the time of death was twenty-nine, but in those cases where the appendix was the seat of the disease the average age was only seventeen. Men were more frequently the subject of this affection than women, in the proportion of nearly 2 to 1. Among the entire number no fewer than 27 originated in disease of the small intestine, the larger portion of the bowel being only affected in 7 cases, and in 4 of these the vermiform appendix proved to be the seat of the fatal perforation. The greater mobility of the small intestines and the relative thinness of their walls afford an ample explanation for the more frequent occurrence of perforation in this region of the gut, while the fact that acute peritonitis should be such a frequent result of the accident is readily understood when it is mentioned that the various coils receive an entire investment from the peritoneum, and that their contents, being of a liquid nature, can readily diffuse over the whole surface of the serous membrane. Of the 27 cases situated in the small gut 3 occurred in the duodenum, 3 in the jejunum and 21 in the ileum, while those due to disease of the large intestine comprised 4 perforations of the appendix, 1 of the cæcum and 1 in each of the ascending and transverse portions of the colon. Although the reports in many of the cases fail to state the exact position of the fatal lesion, there are still a few facts which serve to throw some light upon the various causes which predispose to perforation. It is well known that simple ulceration of the duodenum is almost invariably situated within a few inches of the pylorus and is very liable to terminate in fatal peritonitis. Now it has already been mentioned that tuberculous ulceration of the duodenum is exceedingly rare, and that when it does occur the disease is more common in the lower portion than in the neighbourhood of the pylorus. In 4 cases where perforation took place in this part of the intestine no fewer than 3 were situated within two inches of the pyloric orifice, and in each case acute general peritonitis ensued upon the accident. We are accordingly forced to believe that although a tuberculous ulceration of the first portion of the duodenum is of very unusual occurrence, the disease is in this position fraught with infinitely greater danger to life than when it attacks any other portion of the intestinal tract; a result which is probably due to the corrosive action of the gastric juice on the mucous membrane when in a state of disease. Of all the causes predisposing to perforation mechanical strain on the walls of the bowel is perhaps the most important. It is a common observation that rupture is particularly liable to occur when the ulcer occupies a spot where the gut is habitually bent or kinked; and there can be little doubt that the hinge-like movement which obtains at such a bend in the coil must exert a very deleterious influence upon the wall of the intestine, already weakened by disease. Perhaps the most interesting feature in this connexion is the part played by a permanent increase of tension in the fluid contents of the bowel. Every pathologist is aware how easy it is to blow out the base of an ulcer by passing through the gut a stream of water at a high pressure; the probability of rupture depending directly upon the thinness of the floor of the ulcer and the pressure of the aqueous stream. Now in 6 cases perforation is said to have occurred within twelve inches of the ileo-cæcal valve, and in no less than 5 of these the valve itself is described as much thickened and ulcerated, with its diameter considerably narrowed. In another case, where perforation took place in the ascending colon, it was noted that the bowel was considerably dilated owing to the presence of a tuberculous stricture four inches lower down. It is probable therefore that under certain conditions the progress of the ulceration may lead to considerable narrowing of the diameter of the bowel and the increase of tension thus induced may relieve itself in the direction of the peritoneal cavity.

As a general rule perforation only ensues upon extensive

<sup>16</sup> Bulletins de la Société Anatomique, p. 383, 1846.

destruction of the intestinal tract by the tuberculous processes; but among our cases there occur one or two exceptions to this rule. Thus in one instance a single ulcer the size of an almond had formed in the ileum and death had resulted from rupture of its floor. In another case fatal peritonitis owed its origin to destruction of the vermiform appendix, which proved to be the only portion of the bowel affected by tuberculous ulceration. Although perforation usually arises from a progressive destruction of the wall of the gut from within outwards it appears that under certain conditions it may occur in a totally different manner. In two cases the disease is stated to have commenced in the peritoneal and subperitoneal tissues, extending inwards toward the lumen of the bowel in the form of hemispherical masses covered by the submucous and mucous coats of the intestine. Ulceration but rarely occurred over the summits of these tuberculous tumuli; but in both the instances under notice the caseous material had undergone softening at one spot, and eventually discharged itself in either direction, and so had given rise to escape of fecal matter into the cavity of the peritoneum. In another case an abscess had arisen in connexion with tuberculous mischief of the right Fallopian tube, and discharged itself through the base of an intestinal ulcer; the sudden irruption of the intestinal contents into the sac had caused its walls to give way and lighted up an attack of peritonitis. In one remarkable instance a round worm had burrowed its way through the floor of an ulcer, and its exit into the general cavity of the peritoneum had been followed by a fatal stream of fecal material. It has already been mentioned that in six cases a previous perforation had given rise to the formation of a local abscess; and an examination of the locality of these abscesses revealed the fact that in five instances they were connected with the same portion of the bowel which subsequently became the site of the fatal lesion, while in the remaining case a chronic abscess round the cæcum had been followed by a fatal perforation of the duodenum. In all the cases at present under notice fecal matter was discovered in the peritoneal cavity at the necropsy, the intensity of the secondary inflammation in the serous membrane varying according to the length of time which had elapsed between the onset of the perforation and the death of the patient. In three cases the peritoneum was found to be in a state of general tuberculous disease.

*Clinical.*—The symptoms arising from perforation of the intestine are usually so characteristic in their nature that it might easily be supposed that the rupture of a tuberculous ulcer in a case of chronic phthisis would meet with certain and instant recognition. But a comparison of the clinical and post-mortem records of these cases shows only too clearly how readily the disease may escape notice altogether, or its symptoms be confounded with those arising from less important conditions. We find from the clinical histories of the foregoing cases that in nearly three-fourths of the total number the fatal lesion was accompanied by distinct premonitory symptoms. The most characteristic of these was severe abdominal pain, usually coming on from twelve hours to three days before actual perforation took place, but in one instance lasting for nearly a fortnight. The pain was referred by the patient to the epigastrium or right iliac region, and was increased by pressure or muscular effort; in many it appeared to be rendered more severe by the ingestion of food. Vomiting, often of a bilious type, was a constant accompaniment of this condition and sometimes proved so severe as to prevent the administration of food by the mouth. The temperature usually showed a slight tendency to rise, the pulse was quickened, and in a few cases the diarrhoea, which had previously resisted all treatment, either diminished or ceased entirely. In a few instances the abdomen was noticed to have become distended and hyper-resonant on percussion. Such premonitory symptoms are important, as they are obviously dependent upon the condition of local peritonitis which so invariably precedes the final catastrophe, and their early recognition may prove of value by affording an indication for preventive treatment.

Actual perforation is usually sudden in its onset and the symptoms to which it gives rise are then extremely characteristic. In three instances the accident occurred while the patient was straining at stool, in two others it took place as the patient was walking about, while in another it appears to have followed directly upon a severe attack of retching. In each case a sudden and severe pain was complained of, sometimes situated in the umbilical region, but more often referred to that part of the abdomen which contained the diseased organs. In many cases this sudden

onset of pain was accompanied by a sensation of an internal snap, and the patient dwelt upon the fact that something had given way in his abdomen. Vomiting and collapse quickly followed these initial symptoms, the features rapidly becoming shrunken and blue and the surface of the body covered with a cold sweat; the pupils dilated, the pulse became quick and feeble and the mental depression pronounced. In every case the temperature exhibited a sudden and characteristic fall to a point considerably below the normal. If diarrhoea had existed before the accident it now entirely disappeared. When death resulted from collapse it usually occurred within three to seven hours of the accident, but in some life was only prolonged for about an hour and a half. In those cases that survived this stage the symptoms of shock were gradually replaced by those of an inflammatory affection of the peritoneum; the temperature gradually recovered itself and rose somewhat above the normal; the pulse grew wiry with an increased rapidity of beat; vomiting became urgent and the abdomen exhibited all the characters indicative of diffuse peritonitis. Death finally ensued from cardiac failure after being postponed for thirty-six or forty-eight hours. It is clear, therefore, that perforation may bring about a fatal result in two different ways—by direct shock or from acute general peritonitis; and it is worthy of notice that the immediate danger from shock bore a definite relation to the position and size of the perforation; for the higher the site of the lesion in the intestine and the more rapid the subsequent extravasation the more profound and quickly fatal proved the subsequent collapse.

The train of symptoms indicated in the foregoing sketch are common to all cases of perforation of the gastro-intestinal tract irrespective of its cause, and their supervention in a case of chronic phthisis would admit of but little doubt being entertained as to the exact nature of the complication. But under certain conditions it is found that rupture of a tuberculous ulcer may be accompanied by symptoms of the most equivocal nature, and it is to such abnormal varieties that we would venture to draw special attention. In nearly one-fourth of the entire number of cases the patient appeared to succumb from gradual exhaustion, and the autopsy, which revealed that death had resulted from purulent peritonitis following intestinal perforation, afforded a complete surprise to those who had watched the progress of the case. The question therefore arises why the same lesion should in some instances be followed by such a characteristic and severe train of symptoms while in others its effects are hardly to be distinguished from those of the primary disease, and although it kills, why it should do so in such an unostentatious manner. The answer appears to be that in order for fecal extravasation to be accompanied by clinical phenomena of a pronounced type it is requisite that both the peripheral and central portions of the nervous system should be capable of immediate reaction to a sudden stimulus. But if either the central nervous system or the surface of the serous membrane be previously deprived of its natural irritability from exhaustion or disease, then the symptoms of shock and subsequent inflammation, which under ordinary circumstances are so characteristic of perforation of the bowel, will be either indifferently developed or even entirely absent.

In looking over the cases which presented but ill-defined symptoms of peritonitis, we find they are capable of being arranged in two divisions according as the central nervous system or peritoneum appear to have been primarily at fault. In the first case the symptoms of the accident were unable to exhibit themselves on account of being masked by the profoundly asthenic condition of the nervous system, while in the other they remained latent during life, because the surface of the peritoneum had been deprived of its natural irritability owing to its previous invasion by miliary tuberculosis. That acute general peritonitis may supervene during the latter stages of chronic phthisis without arousing any suspicion of its presence in the mind of the physician has been the subject of frequent remark, and of the difficulty which such cases of masked peritonitis present in diagnosis the following offers a fair illustration. A youth who was the subject of advanced phthisis complained of diarrhoea, accompanied by occasional attacks of nausea and pain in the right iliac region of the abdomen. A few days after admission into hospital and without any marked accession of pain he commenced to vomit and was soon unable to retain any nourishment in the stomach. The temperature which had ranged about 101°F. showed at first but little variation, but afterwards gradually fell

with the rapid progress of exhaustion. No complaint was made of abdominal pain, and on examination nothing abnormal could be detected, with the exception of some slight general tenderness on pressure. The diarrhoea appeared to increase in severity rather than to diminish. The vomiting, however, proved intractable, the pulse grew quicker and weaker, the tongue became dry and brown, sordes collected about the teeth and lips, and the patient succumbed in four days to a progressive asthenia. The persistent vomiting and diarrhoea without collapse seemed to indicate an inflammatory affection of the gastro-intestinal tract, but the necropsy proved that death had really resulted from general purulent peritonitis, and that the rupture of a tuberculous ulcer in the vermiform appendix had allowed faecal matter to escape into the cavity of the peritoneum. The clinical records of the remaining cases afford but little help in formulating any rules for the diagnosis of this form of the disease. Abdominal pain may be present throughout the illness, but its onset is never sudden or accompanied by collapse, and indeed the general tenderness over the whole of the abdomen seldom exceeds that which arises from the presence of intestinal ulceration. Occasionally the abdomen may become distended and tympanitic on percussion, but in the majority of our cases these abnormal signs appear to have been absent. Vomiting is always the prominent feature, though it varies considerably in its severity in different cases. Unlike the more sphenic variety of the disease, the symptom of constipation is often absent and in not a few instances, as in the one already referred to, diarrhoea proved exceedingly troublesome. The temperature varies in different cases, sometimes showing an inclination to rise above its former point, but more often gradually declining with the approach of death. The pulse exhibits a progressive quickening with enfeeblement of its beat, the first sound of the heart soon becomes toneless or inaudible, the tongue appears dry and brown with sordes about the teeth, and the face often acquires that peculiar drawn and sunken expression so suggestive of acute abdominal disease. The exact duration of life in these cases is difficult to estimate owing to the absence of any positive data concerning the onset of the perforation, but in many instances death seems to have been delayed from five to nine days after the vomiting commenced.

With regard to that variety of symptomless peritonitis which we have alluded to as "latent" the cases at our disposal can only furnish us with three instances in point. In each there had been a long-continued complaint of abdominal pain and diarrhoea, and in two cases the existence of fluid in the peritoneal cavity had been diagnosed some days prior to death. The patient appeared suddenly to grow worse without any adequate cause being discovered, but after death it was found that chronic tuberculous disease of the peritoneum was associated with faecal extravasation arising from perforation of the bowel, which from the appearance it presented was obviously a day or two old. It is now a well-recognised fact that tuberculous disease of the peritoneum renders that sensitive structure proof against many sources of irritation which, under normal conditions, would excite intense inflammation. Consequently it may be taken for granted that when once the serous membrane has fallen a victim to tuberculous disease even faecal extravasation will encounter some difficulty in exciting acute inflammation of its structure, while from the impaired sensibility of the serous surface the accident will also fail to produce that sudden reflex inhibition of the vital organs which is commonly termed "shock." Although the notes on these cases are extremely scanty it would appear that the sudden supervention of intractable vomiting and rapid asthenia in a case of tuberculous peritonitis with intestinal ulceration, the progress of which had hitherto been somewhat slow, should suggest the possibility of perforation having occurred.

Symptoms of acute peritonitis not unfrequently ensue during the course of chronic phthisis totally independent of perforation of the bowel, and it is therefore important to recognise the various causes from which they may arise. In the first place, local peritonitis around the intestinal ulcers may prove so severe as to closely simulate in its symptoms the more diffuse forms of inflammation; and in one case which we recently had the opportunity of watching but little doubt was entertained that actual perforation had occurred. The patient, however, lived three weeks and finally succumbed to the pulmonary disease, while the necropsy demonstrated the fact that the abdominal symptoms entirely owed their origin to the existence of two inflamed ulcers in the jejunum. But in such cases as these the onset of the pain is much less

sudden than when due to perforation. Collapse, with a sudden fall of temperature, is absent, and the face fails to exhibit the peculiar expression indicative of fatal mischief in the abdomen. It should also be remembered that actual perforation is of extremely rare occurrence and the subsequent peritonitis invariably terminates fatally within three days.

Secondly, during the same period of time in which our cases of genuine perforation occurred we find the records of nineteen other cases where death had resulted from purulent peritonitis, for which neither perforation of the bowel, tuberculous disease of the serous membrane, nor renal mischief could satisfactorily account. In each instance the bases of the intestinal ulcers were much inflamed, and although it is possible that in a few cases a small perforation may have given rise to the condition without its presence being detected at the necropsy. But the clinical histories of these cases make no mention of a sudden onset of pain attended by collapse, and the absence of this important diagnostic sign is almost conclusive evidence against perforation having occurred in any case. It is probable, therefore, that the condition of general peritonitis was the result of extension by contiguity. Lastly, it is possible that acute tuberculous peritonitis might at an early stage be confounded with an inflammatory affection of the peritoneum arising from the intestinal lesion. In this disease, however, initial collapse is entirely absent, the abdominal pain is more gradual in its onset and less severe, and fever is the rule, not the exception. Here, again, the comparative frequency of the two diseases should be borne in mind, for we find that while tuberculous peritonitis existed in nearly 4 per cent. of all the cases of phthisis which came to a necropsy, acute peritonitis resulting from perforation only occurred 15 times in 2000.

(To be concluded.)

## A PRELIMINARY NOTE ON FLEXION AND VERSION OF THE UTERUS.

By JAMES OLIVER, M.D., F.R.S. EDIN., M.R.C.P. LOND.

OUR text-books on diseases of women, it is true, devote a large amount of space to the consideration of the various flexions and versions of the uterus; that, however, they impart any true knowledge regarding the manner in which these alterations are produced is extremely doubtful. The mere fact that these variations have been recognised for many generations is no criterion. They are apparent and obvious changes, and no high degree of intelligence or great amount of training is requisite for their detection; and had they failed from the earliest period in the history of medicine to attract attention, we should indeed have been justified in expressing the most profound astonishment. The majority of practitioners and gynaecologists even of the present day are, I regret to say, contented to know that they possess that aptitude which enables them to detect alterations in the configuration or position of the uterus—alterations which they cannot, in fact, help detecting. A man endowed with ordinary sight, in looking towards the heavens on a clear night, recognises the stars which stud the azure vault, but without some special training he is unable to determine the distances and magnitudes and courses of the planetary orbs as they roll along the ethereal plains, and these facts are only reached and disclosed by means of an intellectual effort. The various pessaries which from time to time have been devised for the purpose, if possible, of restoring the uterus to and maintaining it in its recognised form and position are carefully enumerated and each is usually described with much exactness. The good effects produced by the application and adaptation of these mechanical agents are duly paraded, but the panegyrist leaves the imagination to picture to itself the manner in which these so-called supports can affect the configuration or position of the uterus and restore this organ to its natural shape and location. "An unreasoned philosophy, even though true, carries no guarantee of its truth. It may be true, but it cannot be certain, because all certainty depends on rigorous evidence, on strict demonstrative proof. Therefore no certainty can attach to the conclusions of an unreasoned philosophy."

Before directing our attention to the consideration of these

changes which produce an alteration in the configuration or position of the uterus let me discuss, first of all, the following propositions, which, says Thomas,<sup>1</sup> "present the views upon the subject of versions and flexions which will be found to bear the test of experience." 1. "Versions and flexions of the womb may, but very rarely do, exist without causing any symptoms, for in themselves they do not constitute disease." The logic of this precept is strange. On authority, but not by reason, we are asked to believe that versions and flexions do not constitute disease and that consequently, although they may not produce symptoms, they are nevertheless much more likely to give rise to discomfort and prove troublesome. Are we to infer that the structural changes which result in the production of these displacements do not constitute disease? If not, they must then be normal variations. No process of reasoning will, I fear, lead us to this conclusion. They are most assuredly the result of some derangement, physical or chemical. Judging alone from the manner in which we are recommended to treat these displacements we are compelled to admit that the alteration, whether in configuration or in position, is in reality the disease. By the application of what "they" term a well-adjusted pessary the uterus will be restored to its natural shape and situation. Now everyone will admit that a system which is reasoned is of some value even although it may not be true, whereas haphazard statements are absolutely worthless, and, worse than this, they are misleading. 2. "By interfering with the escape of menstrual blood, by disordering uterine circulation and keeping up hyperemia, by causing pressure and friction from contact with surrounding parts, and by creating a barrier to the entrance of seminal fluid, they become as a rule of great importance and require special attention." We have no evidence that flexions or versions interfere with the escape of the menstrual blood. Many women suffer more or less during menstruation, and although we may occasionally in such detect some alteration in the configuration or position of the uterus, it does not necessarily follow that the pain is due to an interference with the escape of blood. Frequently we find women with decided flexions and versions who suffer no discomfort whatever during menstruation. We are too apt to jump at conclusions regarding cause and effect, and for this reason statistics are apt to prove fallacious. We have no evidence either that these variations disorder the circulation. Those who assume that the circulation is disturbed forget apparently that they are dealing with organic structures, with tissues which are endowed with a large amount of power of adaptation to circumstances. In the female dugong we have a uterus which presents a peculiar corkscrew shape, but it is perfectly evident that the circulation of the organ is not thereby disordered. If flexion is due to want of tone in the uterus, then the vessels will not receive that amount of support from the tissues and the blood will consequently pass more sluggishly. In this case, however, the circulation is disturbed not by the flexion, but by the cause of the flexion; the disturbance is nevertheless augmented by the configuration or position of the uterus. In the animal and vegetable kingdoms we have abundant proof that mere shape does not interfere with the passage of that fluid which nourishes the tissues. The tendrils and branches of plants perform many gyrations and assume a variety of shapes without the vascular system in any part of its course being necessarily disturbed. Again, the influence of pressure and friction is undoubtedly exaggerated, for everyday we find new growths developing in the pelvis, arising, it may be, from the uterus or ovaries and attaining a great size, and yet the pressure exercised by these produces little or no discomfort unless they become confined, when the increased tension necessarily produces pressure symptoms. It is alleged, too, that flexions and versions are a cause of sterility, as they create a barrier to the entrance of the seminal fluid. If we examine the genital organs of the females of many of the lower animals we shall observe that greater barriers to the entrance of seminal fluid exist naturally in many of them. The spermatozoa appear to experience no difficulty whatever in effecting an entrance into the corkscrew-shaped uterus of the dugong. In the cervix and body of the uterus of the sheep and goat we find groups of laminae presenting the appearance of a number of successive orifices, and many no doubt would be disposed to affirm that these irregularities in the canal would hinder the progression of the spermatozoa. A careful study of the various methods whereby

the process of fecundation is carried on in plants and animals and a close examination of the genital tract in mammalia compel us to admit that the spermatozoa and ova are attracted towards each other and that they do not meet and coalesce simply because they happen to be traversing the same passage. It sometimes happens that this elective affinity is absent and fecundation is then impossible. In the case of fishes, for example, it is this elective affinity—this attraction between the ova and spermatozoa—which keeps the species pure; without this influence hybrids would abound. In the case of the ornithorhynchus we find a cervix uteri located on each side of the roof of the uro-genital canal. Each cervix presents two orifices, one—the lower—communicates with the ureter, whilst the other—the upper—leads to the body of the uterus. If, therefore, the process of fertilisation depended simply upon chance we would be justified in asserting because of the structural arrangement that the female ornithorhynchus would seldom become pregnant, for the spermatozoa would tend to enter the first opening which leads to the ureter, and would thus fail in their mission. It is evident, however, that the spermatozoa seldom, if ever, enter this opening, but are attracted towards that opening which leads to the uterus and ovary. In the macropus major—a marsupial animal—we find also a structural arrangement of such a character that if the meeting of the spermatozoa and ova depended purely upon chance the species would run a fair prospect of being speedily extinguished. 3. "Often being the results, as they are sometimes the causes, of uterine and peri-uterine diseases, their treatment should be combined with efforts at the alleviation of these states." There can be no doubt that the displacements of the uterus are the result of intrinsic or extrinsic changes, but I am fully convinced that if greater caution were exercised in treating these malpositions and altered configurations of the uterus many women would be freed from a great deal of suffering, and many who have become invalided in consequence of a too vigorous treatment would pass through life more comfortably.

Gordon-square, W.C.

#### THE

### RADICAL CURE OF URETHRAL STRICTURE.

By W. BRUCE CLARKE, F.R.C.S. ENG.,

SURGEON TO THE WEST LONDON HOSPITAL; ASSISTANT SURGEON TO ST BARTHOLOMEW'S HOSPITAL; EXAMINER IN SURGERY TO THE UNIVERSITY OF OXFORD.

THOUGH it is universally recognised that strictures of the urethra differ in their situation, cause and arrangement, no attempt has, so far as I am aware, been made to lay down any principles which should guide the surgeon in dealing with these separate varieties. Excluding the traumatic form which, as is so well known, differs from the organic stricture in its extreme intractability, we seem hardly to have advanced much further in our ideas of the causation and pathology of the disease than had John Hunter. He recognised three varieties—*true spasmodic*, *permanent* and *mixed*, and states further and with equal truth that spasm plays an important part in most strictures. Subsequent writers on the question have little to add to this view and the less we stray from these simple statements the greater chance of our getting a clear conception of what urethral stricture is and how to treat it. One point alone we may add to this description to make it complete: we must recognise that congestion plays a very considerable part in many a stricture that comes before us. There is another factor of equal if not of greater importance which remains to be determined before a stricture can be successfully treated. Its exact locality must be determined, and this is doubly necessary, because, for reasons that are not altogether explainable, the locality affected influences both the course which the disease follows and the means which are to be taken for its relief. It is often assumed that the appearance of diseased structures which are so familiar to the student of museums form an all-sufficient basis to enable us to carry out a successful line of treatment. Nothing, I am persuaded, is more untrue and nothing more likely to bring surgery into unmerited disrepute than the acceptance of such a dictum, as some writers have accepted [it without any reservation whatsoever. So far as it goes it

<sup>1</sup> Practical Treatise of Diseases of Women, edition 1880, p. 866.

<sup>1</sup> A paper read before the West London Medical-Chirurgical Society, Jan. 8th, 1892.

cannot be denied that the museum specimen is a most valuable guide, but it must be treated as a servant and not as a master. It represents typical well-marked forms of disease; but the slighter varieties, the beginnings of disease, which are so instructive in teaching us its progress and course and in opening our eyes towards a rational mode of treatment, are practically unknown in museums and are for the most part incapable of representation there. We cannot take a better illustration of this fact than that which is derived from an inspection of hernia specimens in many museums. Direct and indirect inguinal herniæ figure in almost equal abundance and the surgeon who depended only on museum specimens for his knowledge of hernia would perforce conclude that direct and indirect inguinal hernia was of equal clinical significance, whilst a knowledge derived from the living facts of disease would soon convince him that it was their very rarity and not their clinical importance which had prompted the specimen hunter to place direct inguinal herniæ in a bottle. So it is with urethral strictures. Our museums bristle with interesting examples of severe organic strictures, many of them produced by the injudicious use of small and dirty silver catheters, or irritated by the unsparing use of caustics; but of the everyday slight urethral stricture but comparatively few examples are to be found. Not that it is for one moment my intention to find undue fault with the treatment of the period to which these specimens belong. It has now happily passed away, it is to be hoped never to return, but it represented the best thought and the most careful manipulation of a past generation, that was gradually struggling onwards on the lines of surgical progress, and as such should command our intelligent respect; but the specimens which it produced must never be set up as examples worthy of imitation or as indications of the natural course of the disease, unless we are inclined to add the words "exaggerated by surgical treatment." If evidence be needed of such a statement we can find it in the false passages which abound in such specimens, and which may serve as a warning to us against the indiscriminate use of metal instruments. If we would gain a clear knowledge of the best methods of treatment we must extend our knowledge of pathology from the museum spirit to the human flesh, which is more than ever possible to-day by the aid of the urethroscope and cystoscope. What up to quite recently had been a matter of supposition and inference is to-day oftentimes visible to personal inspection. Allusion has already been made to John Hunter's classification of strictures into permanent or organic spasmodic and mixed strictures. Some good reasons may be given for adopting this classification to-day. If the spasmodic variety be first considered it will perhaps conduce to the better comprehension of the other forms, because, as I hope to be able to show, it is the parent of them at any rate in the vast majority of instances. No one doubts that the urethra is at times the seat of spasm, for everyone who has been a few years engaged in the practice of medicine has known instances in which the passage of urine previously easy has been almost if not entirely brought to a standstill either by exposure to cold or by an error in diet. Even Sir Henry Thompson does not deny that in that sense the urethra is subject to spasm, but he would have us believe that such spasm has no connexion with stricture. In referring to the statement made by Otis that deep strictures sometimes disappear after the incision of those situated nearer to the orifice, he makes the following statement. "The deep stricture must be dilated or incised or it will remain as before. If, however, all that is intended by the statement referred to is that a stricture near the meatus may induce spasmodic contraction of muscles connected with the deep urethra, then I have no further concern with the statement; the condition alleged is not stricture; the spasm may or may not occur; its occurrence is a matter of inference or of speculation, not of physical proof, and has no relation to the matter now under consideration."

Many cases of spasm are undoubtedly hypothetical, but all must not be dismissed in so summary a fashion. It is now several years back that I was called upon to treat a case of stricture in the deep urethra, which was said to have supervened upon a recent attack of gonorrhœa and, moreover, a first attack. The patient in question complained that he was often seized with attacks of retention, and though a hot-bath usually relieved him yet a few days later the attack recurred. At times he was quite free from any pain or inconvenience. He was anxious, however, to obtain relief rapidly, as he was about to leave England for some time, and I had arranged to divide his stricture, as, though easily dilatable after a catheter was tied in, it speedily under-

went recontraction and was very painful to the passage of instruments. Under these circumstances urethrotomy had been advised and he was accordingly anaesthetised. I had passed a No. 3 English catheter for him two days previously and did not anticipate any difficulty; but, much to my astonishment, I found that when he was fully anaesthetised the urethra was perfectly patent and no difficulty whatever was experienced in introducing a steadily ascending series up to No. 16 English, though for the larger instruments I was obliged to divide the orifice. I need hardly say that under such circumstances no cutting operation was attempted. After such complete dilatation under the anaesthetic no further difficulty was experienced with catheters, and he soon learnt to pass one for himself. I advised that this should be continued for some little time, and then discontinued, imagining that some temporary cause had induced a spasm and that all further trouble would soon be at an end. I saw nothing of my patient for several years, but within the last few months I have seen him again, and learnt that a few weeks after our last interview he discontinued the use of the catheter, and all went well for several years; but about a year ago—i.e., three years and a half after I had seen him—the ordinary symptoms of stricture supervened, and he sought medical aid. It was dilated and by occasional catheterism he has been kept by this means fairly comfortable, but on the site of the old spasmodic stricture there is now a permanent one of organic character.

Some two years ago I published an account in the Medical Society's Transactions, vol. xiii., page 105, of a somewhat similar case in which electrolysis failed to produce any permanent relief, but which readily yielded to internal urethrotomy. The case is in some respects so remarkable that I need make no apologies for repeating it once more.

W. P.—, aged twenty-four, came to me with a stricture which would admit a No. 4 English catheter. As soon as No. 5 had been held against the stricture for about a quarter of an hour it passed through, and then Nos. 8, 9, 10, 11, and 12 all passed in rapid succession. Nine times in succession did I dilate the stricture, and nine times did he return in intervals of from fourteen to twenty-eight days with his stricture in the same condition. It was clear that one had to deal with a *bonâ-fidâ* case of spasmodic stricture. I examined the man's urethra with the urethroscope and detected on the left side of the canal a small red patch, which was situated as nearly as possible in the locality of the stricture. This at once recalled to me the views on the pathology of rectal stricture which have been so carefully worked out by my friend and colleague, Mr. Harrison Cripps, in his well-known book on "Diseases of the Rectum and Anus," and the case which he records of spasmodic rectal stricture which completely disappeared under an anaesthetic, but which two years later, when he examined the rectum, was converted into a mass of unyielding cicatricial tissue. I soon came to the conclusion that I really had to deal with a spasmodic stricture set up by a small ulcer in the mucous membrane, and that this muscular spasm was gradually being worried into a permanent cicatricial contraction of the canal. This being the case, I at once changed my method of treatment, and advised an internal urethrotomy. The patient consented, and after the operation was completed a No. 16 English catheter was tied in for twenty-four hours, and the urethra kept well dilated by the passage of instruments at frequent intervals for a month. His stricture vanished and nine months later for the first time for eight months I passed an instrument for him and found no trace of his previous trouble. Of course I cannot say that he will have no return, but I feel fairly confident that his case is to be regarded as a true cure, the result of an application of that surgical principle which Brodie so successfully employed in dealing with ulcer or fissure of the rectum.

There cannot be any reasonable doubt that in both these cases just related one had to deal with a true spasmodic stricture and there is, I think, but little reason for doubting that the last case would have gone the way of the first had its downward course not been arrested by a timely urethrotomy. Erichsen records such an excellent instance of extreme spasm existing in a comparatively slight stricture that it is worth while, coming as it does from an independent observer, to record it here. He says: "The influence of anaesthetics in facilitating the passage of instruments through apparently impermeable strictures is very marked. Shortly after the introduction of ether as an anaesthetic agent Liston was going to cut through a stricture that had resisted all

attempts made by his most dextrous hand at introducing an instrument into the bladder; but no sooner was the patient put on the table and rendered insensible than the No. 8 silver catheter, which had been passed down as far as the stricture, and the point of which was to serve as a guide for the knife, slipped into the bladder and thus rendered a dangerous operation unnecessary." Since my attention has been specially directed to the connexion between spasm and stricture I have, almost as a routine treatment, employed an anæsthetic before beginning to undertake the treatment of a case of urethral stricture, and I have been very much struck by the large number of cases in which the stricture has largely increased in calibre under the influence of an anæsthetic. I think I may say it is almost an invariable rule for strictures to yield somewhat, and many yield to a very considerable extent. Whenever a stricture yields largely to an anæsthetic, it is almost certain, when examined with the urethroscope, to display a considerable amount of congestion, and often patches of granulation tissue are seen in its immediate neighbourhood. Much of this spasmodic irritability will disappear by rest in bed and other well-known appropriate means, but there usually remains a small amount of true spasm which yields only to the anæsthetic. If this residual spasm is to be seen in perfection, it must be looked for in an early and recent case, and not in one in which the cicatricial contraction has reached its practical maximum, and where the muscular tissue surrounding the urethra is incapable of producing further constriction. It is needless to add that such conditions are incapable of demonstration by museum specimens, but they can be readily detected by the methods just referred to. These are the cases which, if early recognised and judiciously treated, will I believe yield a considerable number of real cures. The very earliest of all may possibly be cured by the passage of instruments, whilst the more severe cases will yield to electrolysis, or should if this plan fails be subjected to urethrotomy, and well dilated afterwards. Probably one reason why one seldom sees a real cure after urethrotomy is that dilatation is not practised sufficiently, nor with large enough instruments, but of this more later. It is worth while recording that there is no longer the same rooted objection to the word "cure" in connexion with urethral stricture that there used to be. Mr. Mansell Moullin has published an account of some cases in THE LANCET, May 7th, 1892, in which patients had been treated by various surgeons for stricture and in which a cure in its truest sense resulted. It is not so long ago that such a statement would have almost been hailed as evidence of quackery. Once a stricture always a stricture represented the views of twenty years ago. I have myself come across a fair number of cases in which an undoubted cure has resulted, one, I remember, in which a patient had been originally under treatment for stricture by the elder Coulson, and thirty-five years afterwards I saw him. He assured me he had diligently passed a catheter or bougie (I forget which) most religiously twice a week ever since. He had absolutely no trace of a stricture, and I advised the discontinuance of his instrument. I saw him a year or more later, when I passed a catheter for him in order to be able to assure him that there was no chance of a recurrence, and he was still quite free from constriction of any sort. Now what is the best system to pursue for strictures which are not complicated by spasm, or in which at any rate spasm plays a very insignificant part? Can we hold out any hope of cure? It must be admitted the expectation of cure is not often realised, but it certainly does occur sometimes.

Sir Henry Thompson records a case in which, after a stricture had been three times divided by internal urethrotomy, a cure which remained permanent twelve years later occurred, and other instances of undoubted cure may be found. One thing is certain, and that is if once a stricture is completely divided the question of its ultimate cure depends on the subsequent dilatation, on the mode employed and on the thoroughness with which it is carried out. It has been too long assumed that so inveterate is the tendency in a cicatrix to contract that no human power can prevent it. Such a doctrine has done little but retard our knowledge. That cicatricial tissue has a strong tendency to contract may be readily admitted, but it is a tendency which can be overcome in some instances very readily. Why, we might ask, does not the cicatrix which is formed after a radical cure for hernia go on contracting for ever? If only it did do so the hernia would have no chance of requiring a second operation and patients would be more easily cured than they are at present.

Why do not the scars of old strumous abscesses in the neck, after they have been relieved by subcutaneous section, return to their former condition, and why do not burn cicatrices, the most inveterate of all forms of scar-tissue, go on contracting for ever? Simply and solely because treatment is directed towards preventing such a result. Movement of one kind or another is kept up for a sufficient length of time and eventually most of the tendency to recontraction disappears. In the case of the neck this is the more remarkable, because the only possible treatment is rubbing and moving the scar, presumably with the object of preventing the cut bands of scar tissue from rejoining, and there is, as we shall see, some reason for believing that an analogous form of treatment in the case of the urethra will produce in some instances an equally happy result. Rectal strictures of a fibrous nature certainly yield to free division accompanied by persistent dilatation subsequently, and if large bougies are used for about a year, at first daily for ten minutes and after a few months less often, the stricture disappears and shows no tendency to return—a fact which I have been able to verify on several occasions. In some instances I have tried a precisely similar plan with urethral stricture, and with the best results. For this purpose the best instrument that can be employed is a conical steel bougie of as large a size as the urethra will admit. There are very few urethra that will not take with ease a No. 16 English catheter, when the meatus is divided, and in a very large number of patients a No. 18—occasionally No. 20—can be passed without difficulty. Such instruments have the supreme merit of being readily kept clean; they take a high polish and thus pass easily into the bladder, and though at first sight it may sound strange to say so, patients pass them more readily for themselves than almost any other kind of instrument. The reason for this is on reflection quite clear; their weight is such that when passed an inch or two into the penis they glide imperceptibly down the inclined plane of the urethra into the bladder.

I have several cases under observation in which no trace of stricture remains three years after all treatment by dilatation has ceased. But those who have had any experience with hospital patients know how futile it is to expect treatment of this kind to be carried on long and continuously. A few may carry out directions, but the vast majority do not, and in this fact lies the difficulty of the cure. Such experience, however, as I have had of the passage of steel sounds daily, and allowing them to remain in for ten minutes, has led me to believe that dilatation so practised has a far more potent effect even on the very worst strictures than any other plan with which I am acquainted. One man I at present have under observation who was the subject of a very bad ruptured urethra, has been for some months quite free from trouble, while he was so under no other plan of treatment, and at the present time he is beginning to be able to slack off dilatation, because the tendency to recontraction is no longer so marked as it was.

There are classes of cases in which probably there will be no difference of opinion amongst surgeons as to treatment—viz., those cases in which no instrument can be introduced into the bladder. One of two operations must be performed—either that which is associated with the name of Mr. Cock or that which is known as Wheelhouse's operation. The latter is unquestionably tedious, and often attended with considerable difficulty; but the results, both immediate and ultimate, are excellent. Cock's operation, though one of the most rapid methods for the immediate relief of a distended bladder, is by no means altogether free from risk, and often leaves the patient in a worse position almost than he was before the operation, for no attempt is made to promote a continuity between the back and front parts of the urethra; and unless a second operation, somewhat of the nature of a Wheelhouse, is undertaken at a later period, the patient may be compelled to urinate through his perineum for the rest of his days, quite apart from the danger of having his urethra cut completely across, as a result of the first operation for his relief. For my own part I have been inclined to employ more largely than some surgeons the various methods of external urethrotomy from a belief that has been gradually forced upon one that the dangers and evil consequences of relieving a strictured urethra with small instruments, especially when metal ones are made use of, are even greater than they are ordinarily supposed to be. Moreover, though the immediate consequence of an external urethrotomy is often a prolonged and tedious convalescence, yet its ultimate result is with ordinary care both certain and permanent. As an instance of the difficulty which is sometimes met with when

the shorter but more dangerous plan of attempting to pass a small metal instrument by the urethra is carried out, there is a preparation in the Norwich Museum of the bladder and urethra of a surgeon, who had suffered for some years from stricture and for whom a small metal instrument was passed by a well-known London surgeon fifteen years before the patient's death. For fifteen years he never voided his urine except by means of a catheter and after his death it was discovered that the reason for this state of affairs was that a false passage existed, which had left the urethra in front of the stricture and re-entered it in the middle of the prostate. Through this false passage all the urine had been drawn off with a catheter for fifteen years. Nothing probably has tended so much to the better treatment of urethral disease of recent years as the more general employment of rubber instruments in the treatment of small strictures, and it may certainly be laid down as an axiom that whenever a soft guide bougie will pass through a stricture it is capable of treatment by internal urethrotomy, whilst such an occurrence as the one just related will serve to show that however brilliant the passage of a metal instrument may seem to the bystander, the state of the patient afterwards may not be one to be exactly envied. Even if it be granted that success would follow on nine occasions out of ten the surgeon should rather content himself with the more tedious method than court occasional disaster for the sake of a brilliant temporary success.

It has long been recognised and it is now pretty generally admitted that penile strictures demand incision, whilst those more deeply situated are quite amenable to dilatation. It is certainly a curious fact that anterior strictures will not often yield to dilatation, and this is probably due to two facts: (1) The septum pectiniform of the penis is unusually firm and unyielding at its anterior portion; (2) the causes—such as syphilitic sores and very acute inflammations usually of gonorrhoeal origin, which tend to produce anterior strictures, are usually attended with a great deal of inflammation, and thus give rise to strictures of a very unyielding nature. Still the anterior strictures are interesting in other ways. Some of those which are situated within the first inch of the urethra are certainly capable of real cure. In the first place they are visible to the eye, so there can be no dispute about their existence; in the second they can be kept in view whilst they are being divided; and in the third place they can be kept dilated with very large instruments for any period that may be considered to be necessary. If cure be desired in such cases the stricture should be kept dilated for a few minutes daily with a short conical steel bougie for at least six months, after which time the dilatation should be carried on once or twice a week for four or five months more, at the end of which time there will be found to be in most cases (probably in all) but little tendency to recontraction. The accompanying engraving will show the character and shape of the

instrument. Surely if such a result can be obtained with such severe strictures, it should encourage us to hope for cure in those more deeply placed.

With regard to the strictures which are more deeply situated there will probably be much difference of opinion as to how they should best be handled. Many of the slighter ones are so readily amenable to occasional dilatation that few patients are disposed to submit to more prolonged treatment. With the more severe types whenever there is much thickening to be felt from the outside, if there is tendency to congestion, as is shown by their readiness to bleed, or by their admitting instruments of variable size within a short period, no plan has yielded in my hands such good results as electrolysis. I have on more than one occasion published an account of cases with their results several years afterwards, and further experience leads me to assert confidently that in suitable cases excellent results will with care be obtained.

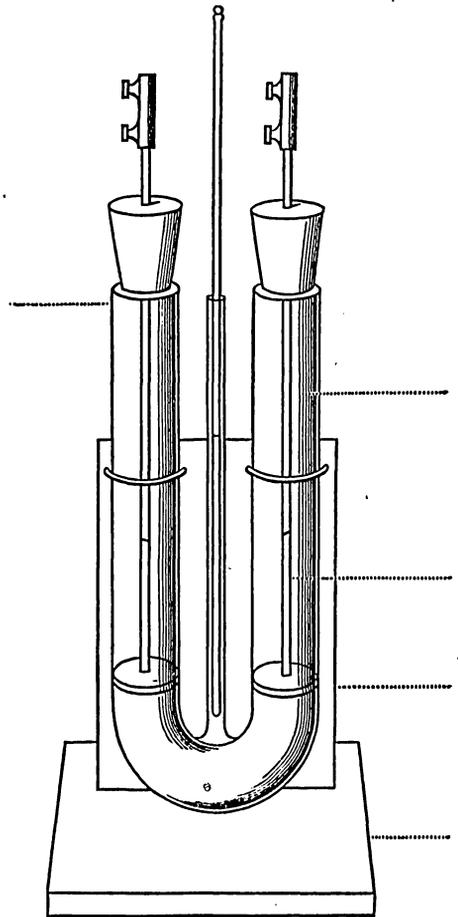

If I were asked to formulate in a few words the most essential points in the treatment of stricture of the urethra I should be inclined to say: 1. Make certain you have a true stricture to deal with. 2. Take the greatest care to keep it dilated for a long time after it has been incised. 3. Where there is much thickening employ electrolysis.

## "THE ELECTRICAL RESISTANCE OF THE URINE AS AN AID IN DIAGNOSIS."

By DAWSON TURNER, B.A., M.D., F.R.C.P. EDIN., &c.,  
PHYSICIAN TO THE LIVINGSTONE MEMORIAL DISPENSARY; LECTURER  
ON MEDICAL ELECTRICITY AT SURGEONS' HALL.

A PRELIMINARY ACCOUNT of part of this research was given in the Proceedings of the Royal Society of Edinburgh on Dec. 21st, 1891, and a further account is being published in the author's "Practical Manual of Medical Electricity." I desire here to give a brief summary of the work and of its chief results. The object of the inquiry was to ascertain the electrical resistances of various kinds of urine, both in states of health and of disease. The measurements were made by means of a Wheatstone's bridge with alternating currents and a telephone according to Kohlrausch's method and at a temperature of 65° F. The engraving is a view of the electrolysis tube used.

It would appear from the observations—some 500 in number—that the specific resistance of a normal urine amounts on the average to about 45 ohms, and that it varies as a rule more or less inversely with the specific gravity. When the specific gravity is high and when the urine holds in solution much salts, its electrical resistance is low, and *vice-versa* where the specific gravity is low, the resistance is high. The amount of urea has but little to do with the resistance in ordinary urines. A number of experiments were made with artificial urines (see tables), and from these it is clearly apparent that the electrical resistance depends almost wholly upon the salts, and that it is only when these are quite absent, or very much diminished that the influence of the

very common cause of death after gastric ulcer. Transfusion was to have been done the next day, but unfortunately her sudden death forestalled us.

### ON PERFORATIONS THROUGH THE ANTERIOR PILLARS OF THE FAUCES.

By G. G. MORRICE, M.D. CANTAB., M.R.C.P.

IN THE LANCET of Nov. 30th, 1889, Dr. Walter Fowler contributed a Clinical Note entitled "The Significance of Perforations through the Anterior Pillars of the Fauces." He concludes with the sentence, "Hence I look upon these perforations as caused by suppurative or phlegmonous mischief in the tonsils; and, considering the circumstances under which they are generally met with, the lesion is most probably a sign of antecedent scarlet fever." As Dr. Fowler does not mention having actually seen the perforation taking place it may be of interest to record the following cases occurring in diphtheria. They took place in Homerton Fever Hospital. I am indebted to Dr. Collie for leave to publish them.

CASE 1.—N. W—, aged ten. She vomited on Aug. 15th, 1890, and was admitted to the Eastern Fever Hospital next day with membrane on the soft palate to the left of the uvula.—16th: The greater part of the left side of the palate is covered with thick jelly-like membrane. During the next week the membrane gradually cleared off, but at the same time an oval piece sloughed out of the left anterior pillar, leaving a hole which would admit a cedar pencil. No sign of diminution in its size appeared while she was with us. Summary of the convalescent stage.—30th: Nasal voice.—Sept. 10th: Paralysis of accommodation.—28th: Attacks of vomiting.—29th: Patellar reflex lost. It was excessive, as often happens, for about two weeks before disappearing. Albuminuria, which had appeared on Aug. 8th, disappeared by Sept. 6th.

CASE 2.—A. K—, aged eight, complained of sore-throat on Feb. 22nd, 1891. On admission to hospital on Feb. 25th there was membrane on the uvula, tonsils and soft palate. A watery discharge from the nose.—March 1st: Uvula encased in discoloured membrane.—2nd: Urine contained much albumen (none on admission).—4th: Voice slightly nasal.—9th: Slough of an oval piece of the left anterior pillar; occasional vomiting; knee-jerks exaggerated.—11th: Drinks return through the nose.—14th: Knee-jerks absent.—30th: Loss of accommodation. April 14th: Strabismus.—15th: Albuminuria ceased; cannot stand alone.—25th: Accommodation regained.—May 5th: No improvement in locomotion.

CASE 3 (from the notes of a colleague).—N. S—, aged two, was admitted to hospital on July 14th, 1891. Bright injection of fauces and soft palate. Yellowish solid-looking deposit on both tonsils.—18th: Deposit has not yet cleared off.—22nd: Well-marked purple bloom on the fauces; a small hole through the right anterior pillar where a piece seems to have sloughed through, large enough to admit a bodkin; no sequela.

Now, with regard to scarlet fever, I have recently seen two children with small perforations of the soft palate and a child, who died, in whom most of the soft palate had disappeared. I have also before me the notes of two other cases, one of whom died of pneumonia and nephritis. These I did not see. My observations up to the present time would lead me to think that the most complete and permanent perforations occur in diphtheria. The striking features about them are the similarity of their position (just above the last molar tooth) and the absence of any indication of repair, their edges being as smooth and uniform as those of a gastric ulcer.

Homerton.

### CASE OF DISLOCATION OF THE METATARSAL BONE OF THE GREAT TOE.

By T. CAMPBELL GREY, M.R.C.S., L.R.C.P. LOND.,  
RESIDENT MEDICAL OFFICER, SWANSEA HOSPITAL.

R. R—, aged twenty-two, engineer, was brought to the Swansea Hospital on June 13th with a recent injury to his right foot. The accident happened in the following manner. The patient's right foot was on the step of an engine, the posterior part being supported by the step, but the anterior

part projecting beyond it. The crank of the engine in its descent struck the projecting part of the foot on its inner and anterior aspect. On examination the skin was abraded over the inner side of the dorsum; the big toe was fixed, the patient being unable to move it; there was a prominence about an inch in front of the tubercle of the scaphoid on the inner part of the dorsum formed by the anterior articular surface of the internal cuneiform; on the inner border of the sole below and behind this was another prominence produced by the displaced base of the first metatarsal bone; this caused a shortening and depression of the arch of the foot. There were no fractures or displacements of any other bones of the foot. I first attempted to reduce the deformity by traction alone, but failed; then, aided by an assistant who pushed forward with his thumb the base of the displaced bone, I was enabled to replace the bone without any difficulty. The case was treated in the usual way; no sloughing of the skin took place, although there had been considerable bruising and at the end of a fortnight the patient was able to begin to use his foot. The rarity of this displacement, unless accompanied with severe injury to the foot, is sufficient excuse for placing the case on record.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Prooemium.

### LONDON HOSPITAL.

#### TWO CASES OF PERINEAL PROSTATECTOMY.

(Under the care of Mr. C. MANSELL MOULLIN.)

THESE two cases illustrate exceedingly well the advantages and the risks of perineal prostatectomy. In the first complete retention was caused by a comparatively slight degree of overgrowth; the gland had spread up the neck of the bladder along its posterior and left lateral wall until it formed two projecting nodules which, meeting over the orifice when the muscles were set in action, effectually closed it. All that was needed was the excision of the offending mass and the division of the growth beneath it in the neck. By this the obstruction to the exit was completely removed, and then the wall of the bladder, which had lost all power of contraction from over-distension, began slowly to recover. Fortunately there had been no previous cystitis, so that the failure in expulsion was due to atony alone and not to the infiltration of the muscular coats by the products of chronic inflammation. In such a case there can be no doubt the perineal operation is the most suitable. The supra-pubic would probably have given equally great relief, but it is certainly more dangerous; cystotomy and drainage might have succeeded, but where it is practicable it is infinitely preferable to re-establish the natural route, and the remaining alternative, catheterism four times a day—by the patient himself or an attendant—could only have had one result. In the second case the conditions were entirely different. Here the lateral lobes were the offending structures; their upward growth had raised a fold between them behind the vesical orifice, but this was firm and rigid, not valve-like, and, though it might have led to the production of a post-prostatic pouch, would not of itself have caused complete retention. The chief difficulty, if not the whole, was due to the way in which the increase in their thickness had compressed the urethra into a narrow slit, through which it was not easy to force the finger. This—aided no doubt by the stricture in front—had created a degree of resistance which the wall of the bladder, weakened as it was by long-continued chronic inflammation, was unable to overcome. Catheterism had become impracticable. The supra-pubic operation would almost certainly have proved fatal, and would not alone have relieved the stricture. Probably in such a case it would have been better to have been content with simple drainage. The bladder

regained a certain amount of power and for a time was able to expel urine through the perineal wound at intervals of two hours; but the task of repair was too great and the sloughing continued to spread. Both lateral lobes have been removed successfully through a perineal incision by Landerer and Willett and one by Wishard; but another case in which the last-named surgeon operated terminated fatally from pyelitis three months later. On the whole the space available is so small and the bruising inflicted during the manipulation is so great that in those cases of prostatic retention in which the chief seat of obstruction is in the lateral lobes it seems preferable either to perform the supra-pubic operation as practised by McGill, or to resort to simple drainage, according to the condition of the patient, and not to attempt complete enucleation through a perineal incision.

A. J.—, a printer seventy years of age, was admitted into the London Hospital on Feb. 12th, 1891, suffering from prostatic retention. The patient was thin and rather wasted in appearance. According to his own account he had always been healthy, although he was suffering at the time from varicose veins and a large chronic ulcer on each leg, until about three weeks before, when he noticed that there was some difficulty in micturition and that the urine did not come in a full stream. He admitted, however, that his night's rest for some time previously had been a good deal interrupted. Retention was complete. A silver prostatic catheter passed easily, but a soft one was brought to an abrupt stop just beyond the bulb and could not be introduced without a stylet. The bladder held from twenty-eight to thirty ounces of urine and had practically lost all power of expulsion, the stream flowing away and following the respiratory movements. The urine was acid, sp. gr. 1013, and contained a trace of albumen and a few blood-corpuscles. The amount was very variable—thirty ounces one day, sixty the next. This continued for a fortnight, no urine coming without a catheter and the bladder not regaining any of its power. The prostate per rectum was only moderately enlarged; from the ease with which a full-sized catheter passed and from the very small quantity of blood in the urine it was fairly certain that the retention was not due to an attack of congestion or thrombosis, which would pass off again. The length of the prostatic urethra was not much increased; from the way in which a soft instrument was stopped the middle lobe certainly projected forward into the channel, and it was therefore determined to make an examination with the finger and if the diagnosis proved correct to remove the obstruction as far as might be practicable.

The operation was performed on Feb. 24th. The perineum was soft and devoid of fat, and as the prostatic urethra was scarcely longer than normal, there was no difficulty in reaching the bladder. The median lobe was found projecting forwards into the neck and was removed by means of a wire creser passed around it, and the top of the left lateral lobe, which had also grown out, was taken off in the same way. An incision was then made along the floor of the urethra in the middle line behind, and the firm tissues torn through by the pressure of a steel director, with the object not only of removing the valve but of establishing a low level channel and keeping the post-prostatic pouch empty until its walls had recovered their tone. A drainage-tube of full size was inserted through the wound into the bladder and continued into a receptacle by the side of the bed. The hæmorrhage at the time was very slight, but a considerable amount of venous oozing persisted throughout the night. The shock, probably owing to this, in great measure was very severe, the temperature falling as much as two degrees, but the specific gravity of the urine that was collected remained practically the same. For some days the patient's condition was critical; there was no fever, the pulse remained strong and a fair amount of food was taken; but he became delirious, losing all control over his actions, and required to be watched constantly. Partly for this reason, partly because the regular washing out of the bladder caused a great deal of pain and disturbance, the tube was withdrawn at the end of a week and the bladder allowed to drain itself through the wound. The urine became alkaline at once, but the decomposition was kept under control by occasional irrigation with corrosive sublimate lotion, a drachm or two of iodoform emulsion being injected afterwards and left in. With the exception of the gradual diminution of the delirium very little progress was made until the end of the third week; then the urine began to come through the urethra, the reaction became acid again, irrigation was stopped and the wound rapidly closed in. After this the bladder slowly regained its power and by the beginning of

April the amount of residual urine was reduced to half an ounce. At the time that he left the hospital (April 13th) the patient was still compelled to pass his urine at intervals of two or three hours, but the condition of his bladder was steadily improving, his general health was perfectly satisfactory and there was every reason to believe that the progress that had been made during the past few weeks would continue.

T. J.—, a silk weaver sixty-six years of age, was admitted into the London Hospital on Dec. 22nd, 1891, suffering from retention. For the last nine years patient had been unable to pass urine without a catheter, which he had been in the habit of introducing for himself. On examination a stricture admitting a No. 5 was found at the bulb with several false passages radiating from it and a moderate enlargement of the prostate, the finger in the rectum being just able to reach its upper limit. The urine, the amount of which varied from forty to sixty ounces per diem, was alkaline, sp. gr. 1010, and contained a small quantity of albumen, with pus, blood and squamous epithelial débris. For some nights after admission he was more or less delirious, evidently suffering from incipient uræmia. This gradually passed off and as the general condition improved, while the difficulty of passing a catheter grew greater and greater, it was determined to divide the stricture, drain the bladder through the perineum and at the same time remove the prostatic obstruction. The operation was performed on Jan. 12th. The urethra was laid open and the prostatic portion examined with the finger. By passing in a sound by the side of it and hooking it against the trigone the bladder could be drawn down sufficiently to feel the neck, and it was found that the lateral lobes were much thickened and elongated and that they had raised up between them a fold of mucous membrane (which proved to contain an upgrowth from the prostate) across and behind the vesical orifice. The median bar was divided, but as this did not give much relief an attempt was made to enucleate a sufficient portion from the lateral lobes by incising the mucous membrane, covering them and working at them with the finger and a Volkmann's spoon. Upwards of a dozen nodules, varying in size from a pea to a hazel-nut, were shelled out in this way; the channel freely opened, so that the finger could be introduced without difficulty, and a drainage-tube of full size secured in the wound and arranged so as to carry off the urine. The anæsthetic given was ether, and the patient stood the operation and the constrained position well; but shortly after being placed in bed the breathing failed and the pulse became exceedingly feeble. Artificial respiration was resorted to and stimulants given freely until the condition of collapse passed off. The next day the pulse was very weak and irregular and, though a fair amount of liquid food and stimulants was taken, the patient continued in a condition of extreme prostration. The day following the temperature rose to 102° F. and the pulse at night to 140. Under the influence of hypodermic injections of digitalin this fell to 100 in the course of the next two days; the strength and fullness of the beat increased; the amount of urine which (though probably all had not been collected) had certainly fallen rose again to 70 oz., and occasionally even more, and for a time there was considerable improvement. The urine was voided at intervals through the perineal opening, the temperature fell nearly to normal, the appetite improved and the patient was evidently gaining strength, although when left to himself he lay in a drowsy, semi-torpid condition. The wound, however, remained in a sloughy state without showing any sign of healing, and a considerable amount of offensive pus came away when it was washed out and also with the urine. On Feb. 4th it was noted that there was some blood in the dressings and the following day about two ounces came away—a quantity small in itself, but sufficient in the patient's condition to make the temperature fall below normal and to bring back the prostration. This in its turn passed off and for some days there was again improvement, but the sloughy condition of the wound persisted, the temperature rose again and became more irregular, the hæmorrhage recurred in small quantities, until at length, on March 15th, as much as four ounces escaped and the patient sank the following day. At the post-mortem examination it was found that practically the whole of the prostate had been removed, a few sloughing shreds around the wall being all that was left. The route into the bladder was perfectly free (a catheter passed in easily through the penis during life), but there was scarcely any evidence of repair. The liver showed an early stage of amyloid disease; there was an old encysted empyema in the right pleura the

existence of which had not been suspected during life; one kidney was very small and contracted, the other was larger, but the pelvis was inflamed and there were some small suppurative foci under the capsule.

### MANCHESTER ROYAL INFIRMARY.

ACUTE INTESTINAL OBSTRUCTION DUE TO BAND; OPERATION; RECOVERY.

(Under the care of Mr. G. A. WRIGHT.)

THESE cases are always worth recording, as showing the value of exploration in intestinal obstruction—a proceeding which adds little to the danger of the condition and saves at least some lives which would necessarily be sacrificed by treatment without operation. For the notes of this case we are indebted to Mr. C. P. Montgomery.

The patient, a young man of twenty, was admitted to the infirmary on March 24th, 1892, with the following history. About eighteen months previously he had an attack of "inflammation of the bowels," with symptoms of (1) constipation lasting for about a week, a little flatus only being passed during the first day or two; (2) a dull pain, not sharp or griping, referred to the region of the umbilicus; (3) vomiting of green bitter matter. At the end of a week the pain subsided, and, on taking salts, the patient passed copious motions and completely recovered, no abdominal tenderness remaining. A month or two later he had another attack of precisely similar character, subsiding in the same way.

On admission the patient was pale, thin and cadaverous-looking. Since the previous Sunday, five days before, he had not had his bowels moved and had passed little or no flatus. Pain and vomiting had been of the same character as in his previous attacks, but more severe and continuous. The abdomen was full and tense, with a peculiar solid feel. There was no tenderness on pressure over the cæcal region, or indeed over any part, and there were no signs of hernia. The patient's diet was restricted to a little beef-jelly, warm cloths were applied to the abdomen and one grain of opium in a pill was given every eight hours. Temperature 99°; pulse 105. Next day there was less vomiting and the patient passed a little flatus, but this improvement did not continue. The vomiting and pain increased, and in the evening of March 28th, four days after admission, the vomiting became stercoraceous in character and the patient much weaker.

March 29th.—An incision three inches long was made in the linea alba, midway between the umbilicus and pubes. On the peritoneum being opened a quantity of turbid serum escaped and the coils of intestine exposed were full, dark and rather congested in appearance. The cavity was explored with the finger and about on a level with the brim of the pelvis towards the left side a sharp tense band, like a thin piece of whipcord, was felt passing between two coils of intestine and constricting a loop of gut behind. There was considerable matting of the coils of gut, especially behind this band, and it could not consequently be exposed to view. There was no inflammatory collection or special adhesion of coils in the cæcal fossa. This band was divided with scissors and passed into the cavity; the peritoneum was washed out with boracic lotion and the wound closed with three deep sutures through the whole thickness of the abdominal wall and peritoneum and a few superficial skin ones.

30th.—Early this morning the patient passed a copious motion. No pain, tenderness or fulness of the abdomen and temperature normal. The patient is kept well under opium and nothing given by the mouth except a few teaspoonfuls of hot water. No vomiting.

31st.—Beef jelly in small quantities given by the mouth. In the morning the general condition was most satisfactory, but in the evening (9 P.M.) the temperature rose to 102° with a pulse, full and soft, of 146. At midnight the temperature was a point less, but the pulse was 160 and the patient much weaker. There was no pain or abdominal distension. Some opium was given, and three ounces of brandy were taken during the night.

April 1st.—Morning temperature 98° and pulse 102. In the evening the temperature only rose to 98·8° and pulse 116, while the general condition was good. No pain or distension.

14th.—From the above date till now there has been absolutely no change in the condition of the patient. His temperature has never been above normal or his pulse above 100 and he has had no pain of any sort. His diet was confined to

beef-jelly till a week ago and was then extended to milk and custard pudding. Last night the bowels were moved twice, the motions being very hard. An enema of half an ounce of glycerine was given and a copious motion followed.

16th.—Wound dressed and stitches removed; healing perfect. Simple enemata ordered every third day. General condition excellent. Fish diet ordered and Battley's solution reduced to five minims at nights.

22nd.—Patient brighter and fresher looking; diet, fish and fowl alternately.

May 4th.—The patient was discharged to-day. Since the last entry his bowels have been moved every day and he has gained weight and strength. All abdominal distension has gone and there is no trace of pain on pressure.

The history of this case corresponded well with the condition actually found at the operation—i.e., local peritonitis with resulting matting and formation of adhesions, one of which probably constituted the band. The absence of any severe symptoms and the previous recoveries seemed to justify the delay in operating, but as soon as his condition became really bad the abdomen was explored and no doubt it would have been safer to have done this even earlier. The somewhat alarming symptoms on the night of the second day were believed to be due rather to prostration than to any serious local mischief, possibly to shock from feces passing for the first time through an injured section of gut, and stimulation was attended with satisfactory reaction.

We also give the following account of another case which was operated on by Mr. Wright a few weeks before, and which presents so many points of similarity that we append it for the sake of comparison, although the operation was performed in private and not in the hospital. Whether in this case the band was the result of previous peritonitis or not must remain uncertain. It is improbable that it was of such recent formation as the attack of abdominal trouble ten days before the illness of which details are given and it seems more likely that the trouble lasting from Feb. 7th to the 13th was also the result of the presence of the band. The fact that it was so thin that it tore through quite readily makes it unlikely that the band was due to any persistent focal relic. Perhaps the most likely theory is that it was formed at one of the early attacks in the previous autumn.

T. C.—, aged about twenty, had a slight attack of peritonitis lasting from Feb. 7th to 13th, 1889, but soon recovered. It appears he had previous attacks in October and November. He was taken ill again rather suddenly after dinner on the 24th. At 9.15 P.M. Mr. Burd was called in. He found the man complaining of very severe pain in the abdomen, which was increased on pressure. The pain was localised to a spot on a level with and slightly to the right side of the middle line of the abdomen, which was tympanitic and slightly swollen. All solid food was vomited, but liquids were sometimes retained. The bowels had not acted for three days. Temperature 100°; pulse 116. Morphia (one-third of a grain) was injected subcutaneously, ice was given to suck and turpentine stupe was applied.

On Feb. 25th the patient was seen twice, the pain and vomiting had ceased and he had slept after the morphia; but in the evening the symptoms recurred, and another dose of morphia was given and an enema of soap-and-water administered, but without result. On the 26th he was somewhat better; on the 27th the abdomen was more distended. Examination of the rectum revealed no cause of obstruction. Temperature 101°; pulse 100. Morphia repeated. On the 28th there was no improvement. Morphia was injected twice. Temperature 101°; pulse 120.

March 1st.—Patient much worse; vomiting distinctly stercoraceous; pain and distension greater. Mr. Burd finding that treatment by opium and starvation after a full trial had failed to give relief advised that Mr. Wright should be asked to operate.

On March 2nd the patient was first seen by Mr. Wright. At that time there was complaint of pain at the umbilicus and in the iliac region, but no iliac tenderness or fulness. There was no visible peristalsis; there was moderate distension of the abdomen. The diagnosis was made of probable matting together of the intestines, and it was decided to open the abdomen. An incision one inch and a half long was made just below the umbilicus, and on passing the finger into the abdominal cavity a band was almost at once felt lying close beneath the opening, the aperture formed by the band was about the size of a five-shilling piece, and through it bowel passed. On making traction upon the band to bring it to the

surface it gave way; its thickness was no greater than whipcord. The abdomen was closed and dressed in the usual manner. In the evening after the operation the pain was much less, but not quite gone. There had been no vomiting. Temperature 98.8°; pulse 108. During the night of the 2nd the man passed flatus and the bowels acted naturally the following morning. The abdomen had so much diminished in size that the dressings had all slipped off. The temperature was normal; pulse 80; there was no vomiting. The appetite returned and in the evening the bowels were again open. A half-grain opium pill every four hours was ordered and milk-and-soda-water was allowed. The case went on well and on the 12th the patient was allowed to get up. On the 22nd Mr. Burd saw him for the last time and he was permitted to go out of doors. He has continued well since.

## Reviews and Notices of Books.

*A Dictionary of Treatment, or Therapeutic Index, including Medical and Surgical Therapeutics.* By WM. WHITLA, M.D. Pp. 948. London: Henry Renshaw. 1892.

A WORK which is so comprehensive in its design necessarily demands much thoughtful consideration, not only from the writer, but equally from the reviewer. Dictionaries are proverbial in not affording material which can be read with pleasure or profit for any length of time. They must be tested at intervals for a due appreciation of their merits and defects. When, as in this volume, both medical and surgical therapeutics are included, the reviewer necessarily approaches his task with a sense of diffidence, conscious of the serious issue of attempting to arbitrate upon subjects covering such a wide range, and anxious to do justice to a work which must have cost the author considerable expenditure of time and labour. It may at once be said that Dr. Whitla has very fairly succeeded in what might almost have been thought to be a superhuman task, in supplying a book which is intended to serve as a guide to the practical treatment of almost everything that is capable of being treated by drugs. The title of Dictionary is used in its widest sense, the principle followed being to arrange in alphabetical order a series of short articles to which the name of a symptom or of a disease furnishes the title. In plan therefore it differs but little from the ordinary therapeutic index which is so often found at the end of text-books of materia medica. From such an index however it differs in the attempt to indicate not only what drugs may be employed, but also the relative amount of advantage that may be expected from them. As usual it will be found that the list is longest where the results are most doubtful and unsatisfactory. Thus five pages are devoted to the treatment of asthma, though it is admitted that the means which afford speedy relief to one patient may aggravate the paroxysm in another, and several of the drugs appear to be only mentioned for the sake of condemning them. As a rule very little is said about the symptoms of the various diseases, but occasionally this rule is usefully broken when most important hints upon treatment depend upon the etiology of the disease. Another satisfactory point worth noting is that Dr. Whitla by no means ignores the value of dietetic and other measures which may be serviceable independently of the action of drugs. Thus, under the heading of Aneurysm, Tufnell's treatment is given in some detail, while the results following acupuncture and galvano-puncture are also discussed. Again, under Diabetes the author quotes at length no less than eight dietaries which have been recommended for this condition. The utility of the general directions for the treatment of dislocations and fractures may be doubted, but the incorporation of the recommendations of the Royal Humane Society for the treatment of those apparently drowned are likely to be of service. A great deal

of space is devoted to Valvular Lesions of the Heart and here the dictionary element is kept in the background; while due prominence is given to the clinical history of the various phenomena commonly associated with these lesions. The writer here permits himself to wander into the picturesque, speaking of coming to "close quarters with the enemy," of "our tried and trusty weapon," and of "skirmishing at long range," all these warlike terms seeming to arise quite naturally after the mention of a "halting ventricle." Still, in spite of these embellishments, this section supplies many useful memoranda, and it should be studied leisurely and in detail instead of being referred to hurriedly when a case of difficulty arises. Less satisfactory is the amount of space devoted to Hydrophobia; the five pages might almost be summed up in a line: "Despatch the patient to Pasteur," this being the logical outcome of the details given from Dr. Roux's statistics and from the lengthy account of the minutiae of treatment at the Pasteur Institute.

It is impossible to criticise the book in further detail. It must suffice to say that, so far as we have tested it, the directions in general appear to be simple and straightforward. While not overlooking the importance of many of the newer remedies Dr. Whitla is careful not to be led into exaggerated statements which can only cause disappointment, and on many occasions where he quotes recent observations he does so with due reservation. The book is remarkably free from printer's errors and is printed in clear type on good paper. It is also rendered more practical by the insertion of numerous formulæ which the author has found valuable or which he has culled from other sources. In a later edition we should be glad to miss the somewhat frequent references to proprietary remedies, soaps and foods.

*A Manual of Chemistry, Inorganic and Organic, for the Use of Students of Medicine.* By ARTHUR P. LUFF, M.D., B.Sc. Lond., M.R.C.P. London: Cassell and Company (Limited). 1892.

STUDENTS of medicine have some difficulty in deciding upon a suitable text-book of chemistry simply because the publishers' lists teem with them. Some manuals are in their way and to an equal degree excellent, some contain prominent imperfections, others are of little or no value at all, while most of the authors generally claim to be familiar with the exact requirements of the class of reader for whom the books are intended. Dr. Luff, the author of the work before us, is fully entitled to the last claim. He has had considerable experience in the teaching of chemical science and especially those sections of the science which bear on the study and practice of medicine. This would lend additional value, of course, to a work which bears his name. All the more disappointing, therefore, is it to note that his book is marred by not a few serious blunders which we may proceed to point out *seriatim*. On page 16 we read: "The molecules of all the other elements [mercury, zinc and cadmium having been cited as examples of molecules containing only one atom] contain two or more atoms; a molecule of potassium contains two atoms and is expressed by the formula  $K_2$ ; the molecule of lead, also two atoms,  $Pb_2$ "; in fact the only elementary bodies, the author goes on to say, containing more than two atoms in the molecule are phosphorus and arsenic. The fact of the existence of a hexatomic molecule of sulphur, by the way, is apparently ignored. He accordingly assumes that the molecular weights of lead and potassium, as well as the rest of the elements, are known with certainty. As a matter of fact the molecular weights or the atomic values of a molecule are only known in the case of fourteen elements, and of these the majority are either non-metals or semi-metals. By far the greater number of the elements are ordinarily speaking non-volatile, as, for example, carbon,

silicon, gold, platinum, or else of such a nature that it is impossible to determine their vapour density.

As if to be in thorough discord with these statements, we find in subsequent pages iron represented as  $Fe_3$ , copper as  $Cu_3$ , lead as  $Pb_3$ , Tin as  $Sn_6$  and so on. On page 115 the formula of nitric oxide is written  $N_2O_2$ ; and accordingly its molecular weight is regarded as 60 and its specific gravity 30. Notwithstanding this it is described merely as "heavier than air" (specific gravity of air=14.4) whereas, according to the above formula, it would weigh more than twice as much. As a matter of fact the specific gravity of nitric oxide is 15, its molecular weight 30 and its formula  $NO$ , while it is a gas but slightly heavier than air. We may be pardoned, in addition to these instances, for pointing out some of the typographical errors we have noticed. Nitric acid, for example, is represented on page 117 as  $OHNO_3$ , and on page 501 ammonium oxalate is written  $(NH_4)C_2O_3$ , and sulphuric acid  $HS_2O_4$ . In the table for the examination of metals, page 499, no provision is made, it may be remarked, for the detection of a lead salt in a dilute solution. Such a solution would not give a precipitate with hydrochloric acid as indicated, but with sulphuretted hydrogen a black precipitate would be obtained. The sulphuretted hydrogen test for lead, indeed, is not even mentioned in this table. Amongst the tests for tin the beautiful purple colour (purple of Cassius) produced on adding auric chloride to a stannous salt is not included, although the reducing action of stannous salts is described.

We have quoted enough to show that the book requires very careful revision, especially if it is meant to compete with existing works of its class; it is evident that more care than has hitherto been taken need be exercised with the proof sheets, and although the general plan and scope of the work will probably appeal to those for whom it is intended, yet it cannot be safely recommended until it is freed from the flaws to which we have made reference.

*Practical Midwifery: a Handbook of Treatment.* By EDWARD REYNOLDS, M.D. New York: William Wood and Co. 1892.

In the preface to this work the author, who is assistant in obstetrics in Harvard University, states that it "is an attempt to furnish to students and inexperienced practitioners a full description of those practical details of conduct which are necessary to the management of every case of gestation, labour, or the convalescence therefrom. It further aims to supply to such men a concise description of at least one method of dealing with each of the emergencies of obstetrical practice." Again, the writer tells us that "the book is mainly intended for the use of those who have already assimilated the more comprehensive but perhaps less definite information which it is the province of the systematic text-books to supply." It will thus be seen that Dr. Reynolds considers that, notwithstanding the numerous text-books on obstetric medicine which already exist, there is room for another, which is to be essentially practical. Let us see how far the book is a success in this direction, for it must be admitted *in limine* that as a scientific guide the volume is far from satisfactory. In treating of the differential diagnosis of pregnancy the author says, writing of fibro-myomata, "slight enlargements of the non-pregnant uterus from the presence of interstitial fibroids may sometimes give rise to the suspicion of early pregnancy. The distinctive points are, however, the greater hardness of the uterus where the enlargement is due to the presence of myomata, the absence of Hegar's sign, the fact that such a uterus is almost always asymmetrical and that the tumours are seldom single and therefore usually present a more or less lobulated outline." We think men of experience will admit that it is the soft oedematous myoma which most closely resembles the pregnant uterus, and of this

variety our author says nothing. In calculating the duration of gestation no reference is made to the practical plan suggested by the late Dr. Matthews Duncan. In reference to the malpositions of the uterus during pregnancy Dr. Reynolds says (speaking of anteversion): "When such a displacement is the cause of annoying frequency or pain in urination, relief may be obtained by recommending the patient to pass as much time as possible in the recumbent position and upon the back; but in any case where the distress is sufficiently extreme to demand immediate relief this may usually be obtained by the introduction of a suitable pessary, such as is ordinarily used in anteversion of the non-gravid uterus." If Dr. Reynolds had first demonstrated that the annoying frequency or pain in urination was due to the displacement, there would be some ground for the treatment suggested; and when he speaks "of a suitable pessary such as is ordinarily used in anteversion of the non-gravid uterus," we must ask him, has he read the literature of the past few years on this question? Surely this bogey of anteversion may now be suffered to remain at rest.

In reference to hydramnion, the author recommends puncture of the membranes or aspiration of the uterus through the abdomen. "This latter operation, if done with sufficient care and with absolute asepsis, should be ordinarily attended by no danger and is usually the better treatment, since it may be followed by a continuance of pregnancy to term." We should like some further information on this point and an account of a series of cases in which this "better treatment" has been employed.

In his remarks on forceps operations, Dr. Reynolds says: "It is a safe rule that forceps should never be applied unless both fontanelles or one fontanelle and an ear have been surely recognised." We are afraid, if this rule were always adhered to, many women and children would suffer. We cannot agree in his recommendation of pilocarpine in eclampsia, and in his remarks on placenta prævia the author devotes too much space to the use of the tampon and too little to the method of Dr. Braxton Hicks. While we have freely criticised some parts of the book, there are others which we can most cordially praise. His remarks on "Antisepsis and Preparations for Labour," on the "Preservation of the Perineum," on the "Management of Breech Presentation," and on the "Treatment of Septicæmia," are well worth reading. In conclusion, while we cannot recommend this work as one to take the place of the many useful text-books on obstetric medicine which exist in this country and in America, we believe that teachers, practitioners and students will in its perusal obtain many useful hints.

*Land, its Attractions and Riches.* By Fifty-seven Authors. London: The Land Roll Office.

THE editor of this volume has persuaded himself that his object in the undertaking to which he has addressed himself is the national one of attracting capital to the land and thereby restoring the rural population, procuring a renewal of prosperity for the British farmer and both directly and indirectly benefiting commerce. His book will leave upon his readers the impression of being a very elaborately got up circular serving to advertise the eligible properties offered for hire and sale by an eminent firm of land agents in Lincoln's-inn-fields. There is no reason in the nature of things why a business circular, drawn up in literary form, should not make a very readable and useful book; but having conscientiously discharged the reviewer's duty upon this volume, we are driven to confess that it is rather heavy reading.

*Diseases of the Nasal Organs and Naso-Pharynx.* By WHITEFIELD WARD, A.M., M.D. New York and London: G. P. Putnam's Sons. 1891.

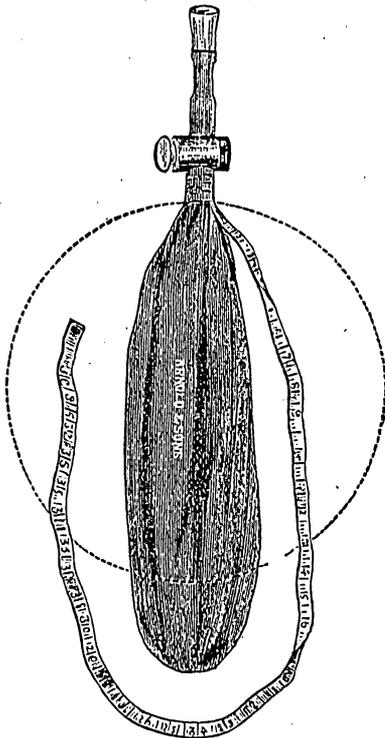

THIS is a well-written little book of 165 pages. The type is good and clear and the illustrations generally well

executed. By the exclusion of much that is doubtful and by a concise method of expression the author has managed to compress into this book much that is useful and important regarding what is known of nasal diseases. A judicious selection of prescriptions is here and there inserted. The size of this work forbids its pretence to be anything like a complete treatise on the subject. At the same time we think the directions for operating in some instances are too meagre and we note with surprise how little attention is drawn to the methods of operation for adenoid growths and their symptoms and pathology. This little book will, however, be a useful addition to any medical man's library.

## New Invention.

### A SIMPLE AND PORTABLE SPIROMETER.

THE spirometer is an instrument now little used, more on account, perhaps, of its bulk and cost than anything else. This infrequency of use may also be attributable to the fact that the instrument has one use only—viz., the capability of determining one condition—vital capacity, without affording indications of the correlating factors which modify it, and the most important of these is expiratory

force. The accompanying engraving represents a very simple, practically efficient spirometer made for me by Messrs. Arnold. Its capacity will prove equal to all requirements. It consists of an elastic bag exceedingly easy to distend, with a tape affixed whereby the degree of distension can be measured. Expiratory force can be determined by employing thicker bags, which require greater effort to distend, or by making use of a broad elastic tape to surround the bag, instead of the tape generally used.

Crouch-end,

JAMES MACMUNN.

## THE MEETING OF FELLOWS AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

It was scarcely to be expected that a meeting of Fellows of the Royal College of Surgeons of England summoned by the Council without any definite object in view and without any programme of business stated in the summons would lead to any definite results. If it had been originally intended to place before the Fellows all the resolutions which the Council passed at the instance of the committee which sat to consider what further advantages could be extended to the Fellows and the best mode of celebrating the Jubilee of the Fellowship; it is to be regretted that this was not done. Instead of this, the President informed the meeting that there was nothing particular to be brought forward for discussion and then invited the Fellows present to express an opinion only upon the proposals which had been made in regard to the celebration of the Jubilee, carefully excluding the more important resolutions with regard to advantages to the Fellows. Strange as it may appear, there were several Fellows present who were not aware that any resolutions whatever had been passed by the Council which concerned their interests. Consequently a natural complaint was elicited from Mr. Crosby that no notice had been sent to him from the Secretary intimating that it was the intention of the Council to celebrate the Jubilee of the Fellowship. Thereupon the President directed the Secretary to procure and to read to the meeting the report on the public celebration, which was done; but the meeting not having any organisation or cohesion, and having assembled in a spirit of curiosity and readiness to receive whatever might be vouchsafed to them, did not show any signs of a desire for more substantial fare. A long pause ensued, and but for the intervention of Mr. Holmes the assembly might have dispersed without any discussion. Mr. Holmes rose to express his gratification at the action of the Council in calling the Fellows together, his approval of the arrangements for celebrating the Jubilee of the Fellowship, and to call attention to the desirability of the Council consulting the Fellows of the College before coming to a decision on matters of great professional interest and importance, instancing the University question and the five years' curriculum. His remarks were couched in a friendly and courteous vein and there was nothing to invite the attack which was made on him by Mr. Christopher Heath. Most gladly should we have abstained from alluding to the subject if a sense of professional duty did not compel us to deprecate the spirit and substance of Mr. Heath's remarks, and we shall only add that the sense of the meeting was admirably expressed by Dr. W. J. Collins, who in a few well-chosen words expressed his deep regret at such an episode occurring at a friendly conference at which it was understood that the hatchet was to be buried. Dr. Collins concluded with a suggestion, of which Mr. Howse expressed his approval—viz., that the Fellows should choose a body like the annual Committee of Convocation of the University of London to consider questions affecting the interests of the Fellows and to be the medium of communication between the Fellows and the Council. Before another meeting of Fellows is called we must hope that the Council of the College will see its way to adopt regulations under which the proceedings may be conducted in a formal and businesslike manner. We trust also that the President or other chairman at these meetings will not allow personal attacks to be made in the future.

VICTORIA INFIRMARY DISPENSARY, GLASGOW.—The ceremony of inaugurating the dispensary in St. James-street, Paisley-road, in connexion with this infirmary, took place on the 4th inst. It had been for some time the intention of the governors to establish district dispensaries on the south side, but hitherto they had no funds to spare for that purpose. Under these circumstances Mr. A. Cameron Corbett, on behalf of himself and his sister, had presented the governors with 1000 guineas, which would enable them to equip the dispensary and work it for the next three years. It will be opened to the public on Wednesday next.

# THE LANCET.

LONDON: SATURDAY, JULY 16, 1892.

THE result of the election to the Council of the Royal College of Surgeons of England which took place last week, gratifying as it is to ourselves, will be eminently satisfactory to all who are interested in the welfare and good government of the College. That Mr. THOMAS SMITH would head the poll was in accordance with general expectation and his success was thoroughly deserved. Mr. DURHAM's re-election was by no means so certain and he received 82 votes less than Mr. THOMAS SMITH and 34 votes less than Mr. JOHN TWEEDY, who polled 237 votes (including 21 plumpers) and was second on the list of successful candidates. Mr. HOWARD MARSH, who received 200 votes and not a single plumper, and who took the fourth or substitute seat, was closely pressed by Mr. HENRY MORRIS with 188 votes (including 8 plumpers). At a considerable distance followed Mr. JEREMIAH MCCARTHY with 106 votes (8 plumpers), Mr. WILLIAM ANDERSON with 90 votes (1 plumper), Mr. MACKELLAR with 86 votes (3 plumpers), Mr. WARRINGTON HAWARD with 77 votes (including 18 plumpers), and Mr. GEORGE COWELL with 75 votes (4 plumpers). The total number of valid votes was 516—an increase of 73 over last year, when considerable apathy prevailed—and out of the 516 votes the number of plumpers was 74. With so many candidates and so uncertain an issue it was felt in certain quarters that the right course was to plump for a candidate whose return was specially desired lest he might lose his seat if the votes were split. Hence it was that Mr. TWEEDY received 21 plumpers; but as it happened there was no need for this precaution, and had these 21 votes been split in favour of Mr. HENRY MORRIS that gentleman would have been elected in company with Mr. TWEEDY and have stood third upon the poll. We have always deprecated the practice of plumping and it is satisfactory to note that in the four elections that have taken place under the new regulations it has not secured the return of a candidate. In 1889 there were only 33 plumpers out of 600 votes divided amongst eight candidates. In 1890 there were 92 plumpers out of rather more than 500 votes divisible among seven candidates, and no less than 53 of the plumpers were given to Mr. MITCHELL BANKS. Even this number of plumpers did not affect the result as regards Mr. BANKS, for he had a remarkable success, being no less than 141 votes in front of Mr. MARCUS BECK, who was second on the poll. If the plumpers had been split with the other provincial and progressive candidate, Mr. LAWSON TAIT, he would have gained the third seat at the election. In 1891 the plumpers were only 46 among five candidates and they made no difference in the position of the candidates in whose favour they were recorded.

The combinations of votes given at the present election were very instructive. Some voted for the four senior candidates, some for the four juniors; some voted only for candidates at the same hospital—St. Bartholomew's or St. Thomas's, for instance; some voted, as advised in

THE LANCET, for the four candidates whose views were known to be favourable to the elevation of the Fellows; some voted for the four official candidates and some for the two most progressive candidates. But one circumstance could not fail to be remarked—namely, the greater frequency of Mr. TWEEDY's name in the various combinations as compared with that of any other candidate. Mr. THOMAS SMITH received the official vote, the senior vote, the hospital vote and the progressive vote, but Mr. TWEEDY's votes were still more varied. The one great feature indeed of the election was the brilliant success of Mr. TWEEDY. Let it be remembered that Mr. TWEEDY was the junior Fellow, that his name was last on the list of candidates, that his success was not desired by the official party and that his name had been associated with advanced measures of reform, and his election not merely to a seat on the Council, but over the heads of Mr. DURHAM and Mr. HOWARD MARSH to the second position on the poll, assumes an importance which it would not otherwise have possessed. A tribute it is to his sterling qualities and his personal merit, but it is also a significant intimation to the Council that a large and influential body of the Fellows are in favour of the views which have been advocated by the Association of Fellows (of which Mr. TWEEDY has been a most prominent member since its first formation) and which have been unceasingly advocated in the columns of THE LANCET. Those who decry the influence of the Association, or the progress which the views of the Association have been making within the last two years amongst the Fellows of the College, may yet find reason to alter their opinions, and to be satisfied that the time has come for making real and substantial concessions to the Fellows of the College. The records of the poll prove how easy it would have been for the Association to secure two seats this year, and with good candidates it is not unlikely that in the next election such a result may be secured.

THE disastrous landslip on the line between Bologna and Florence, the serious casualty of the same kind on the Vorarlberg railway, the appalling explosion on board the steamer on the Lake of Geneva, and the terribly destructive inundation near Chamoni, are the more outstanding from among a series of calamities which, occurring at the very opening of the holiday season, cannot fail to prove deterrents to the intending tourist in Italy, Austria and Switzerland. Whether these casualties were to be anticipated, or to what extent they were preventable, will doubtless be elicited at the official inquiry about to be opened on each of them. Murmurs, indeed, in the case of the first three, are already audible as to a more than probable neglect of duty on the part of railway and steamboat managers alike. Whether this be correct we cannot judge, but in Italy the public press has asserted that the "accident" on the Bologna line was no accident at all; that the landslip was a long-admitted danger of which warning had been given years and years ago, and that the reluctance to incur immediate expense, so characteristic of Italian enterprise, is responsible for an engineering inactivity the reverse of masterly. Strictures to the same effect may be gleaned from the accounts given of the steamboat disaster in Switzerland

The boiler is alleged to have been lately examined by an inspector, who is said to have "found cracks in it," but thought "it might run for another year." The Austrian contribution to this tale of casualties has also its candid critics, while it has got to be cleared up whether the Chamonix cataclysm was not more due to man's neglect than to "the visitation of God." Pending official investigation, we repeat, it is not for us to appraise the justice or the injustice of such charges, but the remark may surely be permitted us that if neither regard for public safety nor consideration for private interests can avail to deprive continental transit of its dangers, the inducements to venture life and limb along these familiar lines of route are very appreciably lessened. Of the three countries in which these "accidents" have occurred, Italy, Switzerland and, in a lower degree, Austria are dependent on the tourist season for a large proportion of their yearly revenue. The wave of travel which sweeps over them every summer or winter has in their case been likened to the inundation of Lower Egypt by the Nile—a visitation beneficent for all. But the deflecting of the Nile river above Khartoum and its diffusion over the surrounding desert would not be a more suicidal operation for Egypt than the wanton scaring away of the English-speaking visitors would be for Italy and Switzerland. A few more such disasters as those which have brought death and suffering worse than death to the travelling public on the Bologna route, and on the Lake of Geneva, and Italians and Swiss will have but themselves to blame for a loss of income which neither can afford to incur and at the same time live and thrive.

Last year there was quite an epidemic of railway accidents in Switzerland and on at least one very important line the shareholders had to submit to a total suspension of dividends. In Italy catastrophes of the same kind were far more frequent than usual. But in the case of both countries these were due to their traditional causes—collisions or landslips. Now, however, a new development of railway engineering has opened up fresh sources of danger, just long enough in operation to have given some earnest of the frightful consequences which neglect or failure on the part of an overworked and underpaid service may entail. We allude to the electric railways connecting the low-lying plain with the upland regions of the Alps and Apennines. Many of these are triumphs of engineering skill, in which the water-power of mountain torrents has been utilised for the generation of electricity required to "balloon" the passenger from lake or champaign to hill-plateau or aerial peak. The convenience of such modes of transit is immense, a few minutes sufficing to waft the tourist and his *impedimenta* up the mountain-side to its top, a destination which formerly could be reached only by long hours of toilsome zigzagging in a diligence or on mule-back. But the risks are also tremendous. In Switzerland who can have failed to observe a hill-side railway looking at a distance like a fire-escape propped up against a precipice and relying on the steadiness of its engineering safeguards to ensure the train against backing down with a run into the lake or the ravine below? Not many months have elapsed since the electric tram-service from Florence to Piesole, on its descent from the latter terminus, got quite beyond the conductor's control and crashed into a roadside

wall with its living freight, of whom the majority were either killed on the spot or maimed and injured for the rest of their lives. True, the precautions taken in such modes of transit are manifold; but the risks of accident are not less so, and who can say whether the casualties which have of late years multiplied on the familiar Swiss and Italian gauges, broad or narrow, may not have their counterpart in those mountain railways worked on principles so complicated and requiring an inspection more vigilant and a renewal of material more constant and thorough than the company's returns can well afford?

Of the sanitary dangers to which the English-speaking visitor is exposed—much less, it is fair to say, in Switzerland than in Italy—we have already treated. Year by year witnesses an improvement, even in the outlying tracts of the Italian peninsula, on the mediæval hotel appointments and service with which the sojourner in search of sun or rest had often to put up with. But this year we are more than likely to see a descent of cholera on the Mediterranean shores, with the authorities at the various seaports hardly more prepared for meeting it than formerly. Disbelief in quarantine and sanitary cordons is now, thanks to an enlightened hygiene, pretty well established in those regions. We wish we could point to a compensating advance in their public or personal cleanliness, in pure and abundant water-supply, or in a really effective system of drainage. One department of public health, it is just to indicate, the Italians have at length put on a satisfactory footing—we mean the protection of food and drink against deleterious counterfeits. The energy of the State inspectors in detecting adulterated bread stuffs, tainted meats, "falsified" wines and bogus mineral waters, and in summarily bringing their authors to justice, if it has shown the extent of the hitherto permitted evil, has also proved the thoroughness of the repressive measures brought to bear upon it. The extension of such real public service to other departments equally important in the common interests is imperatively required to reassure the English-speaking visitor or resident. Let such clients of the sunny south or of "the playground of Europe" be persuaded that they can reach their destination not only in comfort but with safety, and that when arrived there they will run no avoidable risks of disease, endemic or imported, and a satisfactory *modus vivendi* will soon be re-established, to the mutual advantage of entertainer and guest.

THE out-patient system has been let off easily by the Committee of the Lords. This is especially the case in the final portion of the report. Still a great mistake will be made if attention is not given to the evidence on this subject and to some of the admissions of the Committee in regard to it. We have already referred in a general way to the conclusions of the Committee on it, but the out-patient department is so huge and important in its bearings that we deem it necessary to revert to it again in more detail. The very existence of the out-patient department is of comparatively recent date, and in the hospitals of Edinburgh it does not exist. There they have a far larger proportion of medical students to their population than we have in London and also abundance of poor, but somehow or other the system

has not taken root. In the metropolis it has assumed vast — nay, alarming — proportions, so that all, whether from a social or a medical standpoint, are calling for some limit to be put to it; and not a few advocate its entire abolition. At the London Hospital 100,000 patients a year are treated, at St. Thomas's Hospital 25,000, at the Middlesex Hospital 38,000, at University College Hospital nearly 40,000. These numbers are spoken of with pride rather than with doubt, as if the hospital authorities were quite sure that they were doing right, and knowing well that the figures strike the public and move the charitable, who are not too inquiring in their turn of mind. At Guy's Hospital on a busy day 480 out-door patients are attended to, including casualty cases. It is a libel to say that patients are seen at St. Bartholomew's Hospital at the rate of one a minute, for it was estimated that, deducting the casualties (which are seen only by the resident staff) and the more serious of the out-patient cases, three or four minutes are devoted on the average to each of the remainder. The Committee admit that the number of persons coming for out-patient treatment often puts a strain on the powers of the staff. Some of the most doughty defenders of the out-patient department further consider that the vast majority of the cases are trivial and that the patients need only to be told to continue the treatment. The Committee go even further and say: "The majority of persons who present themselves at the out-patient department of a hospital come with trifling ailments *which are quite unsuitable for hospital treatment.*" The italics are ours. It is a resort according to some not only of the ailing, but of the idle and those who simply want to talk. At some hospitals the social aspects of the department are made still more attractive by the establishment of refreshment bars or coffee stalls.

The detention of those who are really ill in the out-patient rooms is an objection touched by the Committee, but not satisfactorily disposed of. The Committee suggest the incidental advantage that such delay may have in deterring unsuitable cases. This is just what on their own showing it does not do, seeing that the numbers go on increasing, including a majority quite unsuitable for hospital treatment. Those who are really ill suffer all the disadvantages of a rough and tedious system of attendance which attracts hundreds of thousands of unfit cases. The Committee, their "Conclusions" notwithstanding, have thus given strong confirmation to the belief of medical practitioners that the out-patient department is one that should be greatly curtailed in its proportions, and brought into touch with more self-respecting methods of treating sickness in the working classes. The Committee go with much detail into the further arguments against such wholesale arrangements. They deal with the objection that such a system is not only destructive of self-respect and providence in the poor, but is a gross injustice to the general practitioners who work in the crowded and poorer districts of London and the hardships and self-denial of whose life are known only to themselves. "A witness" was examined who expressed the opinion that the practitioners injured by the wholesale competition of the hospitals were not those whom it was generally desirable to protect. We are glad that such evidence proceeded from

"a witness." We should be sorry to think that any plural number of witnesses throw doubt on the obvious fact that such hospital arrangements must operate against all practitioners. The Committee themselves admit as much in the following sentence under the head of Sweating of General Practitioners (p. 32, third report, 12): "The competition of free treatment would naturally tend to drive down the fees of the private practitioners, and this was stated to be an urgent evil and one which has been going on for ten or fifteen years." It cannot be denied by anyone whose eyes are not wilfully closed that between the attractiveness of out-patient departments and the introduction of petty payments by out-patients, conveying an idea that they are purchasing advice and medicines, the creditable reluctance to go to hospitals has been much broken down and that the medical practitioner has more and more been made a mere convenience chiefly at nights and in great emergencies. In days when working men did not get such good wages as they do now, numbers of them regularly employed and honourably paid a neighbouring private practitioner, who knew their children and acquired that knowledge of their family health and circumstances which doubles the value of medical attendance. The breadwinner himself might be in a club, but a reasonable midwifery fee and a pound or two moreover for the family doctor were easily and cheerfully provided. The great hospitals and the little ones are doing a great deal to upset such an honourable system and the fact is as good as admitted by the Lords' Committee, who go carefully into proposed remedies without much apparent confidence in their sufficiency, and who withhold that word of efficient condemnation for so huge an abuse which we think was expected of them. Inquiry into personal circumstances, limitation of numbers, and payment by patients to hospitals are each reviewed. In Manchester, as is well known, the unfit cases have been weeded out by an efficient system of inquiry and the numbers greatly reduced. In London such is the scale of population and the difficulty of estimating the status of the applicants that little effective work has been done. In 22,000 cases at the London Hospital inquiries were made in 800, or 1 in 27. What are these among so many? We can only remind hospital authorities that this great blot in their administration remains. The Committee have fastened responsibility for it upon them, and they will not be allowed to escape criticism till it is wiped out, and charity for really fit cases is encouraged by careful elimination of the unfit.

THE BOWMAN Lecture of the Ophthalmological Society was this year delivered before a numerous audience by the distinguished Professor of Ophthalmology at Heidelberg, THEODOR LEBER. For many years past Professor LEBER has been engaged in working out the pathology of the inflammatory process, which can nowhere be studied to greater advantage than in the cornea; and it is not surprising that he took that subject for his theme and presented to his hearers in a condensed form the contents of the large and important work he published a few months ago, the chief points in which we recently translated for the benefit of our readers. After a brief but appreciative reference to Sir WILLIAM BOWMAN and to the loss sustained by the

profession by his death, Professor LEBER acknowledged at once that we are indebted to Sir JOSEPH LISTER for the proof that the purulent inflammation following an injury is caused by inoculation of micro-organisms within the wound. Further inquiry has led to the discovery that their capability to give rise to inflammation and to disease in general depends upon the production of certain poisonous substances which in infinitesimally small quantities are able to cause inflammation and necrosis of the tissues of the body; whilst, on the other hand, the presence of an inert foreign body introduced antiseptically into the tissues leads to no inflammation whatever. Nowhere can this be more clearly shown than in the eye. If a small piece of gold or glass be introduced through a slight wound with due antiseptic precautions into the anterior chamber of a rabbit's eye no inflammation is excited, no pus is found, and this foreign body may continue visible for months or even years either in the aqueous or in the vitreous, which remain unclouded. From this fact it was easy to draw the conclusion that suppuration is only produced by the specific action of micro-organisms. Unfortunately, however, further experiment soon presented stubborn facts which militated against this theory; for a single drop of mercury, rendered absolutely sterile by heat, antiseptically introduced into the anterior chamber of the eye of an animal always gives rise to a circumscribed collection of pus in its immediate neighbourhood, which is distinguished from that which is produced by micro-organisms by the entire absence of microbes which can be shown by the microscope, or which can be obtained by culture experiments. But mercury is not the only substance that can induce suppuration. Metallic copper is equally potent, though Professor LEBER has observed remarkable differences in the effects produced according to the part which may happen to come into relation with the metallic fragment. Should it rest either on the iris or inner surface of the ciliary body, suppuration will certainly be produced; whilst a similar fragment produces no pus when situated in the lens, where it does not even produce complete opacity. The reason of this difference, he shows, lies in the fact that the fragment of copper when situated in the lens is completely enveloped by a thick coating of albumen which effectually prevents it from exercising its irritating chemical action. On the other hand, when in contact with vascular tissues copper immediately acts upon the vessels, an effect that is probably due to the copper being dissolved by the fluids of the eye, on which fact its power of provoking inflammation depends. One of the commonest causes of suppuration—the staphylococcus aureus—readily furnishes proof that its action depends upon chemical substances, for if a pure culture perfectly sterilised the fluid containing them can still produce an intense purulent inflammation when injected into the anterior chamber.

The study of septic inflammation of the cornea shows that the action of the micro-organism extends far beyond the area of its development, so that, as Professor LEBER remarks, a sort of distant action must take place. The lecturer then proceeded to describe the keratitis caused by inoculation of micro-organisms. He took the case of a microbe developing in the centre of the cornea and showed that the effect in the area directly attacked consisted only of retrogressive changes in the cells ending in necrosis. At first, if the action of the microbe is sufficiently intense, neither migration of

the leucocytes nor proliferation of the cornea cells takes place; but after a time there appears a zone of dense infiltration of pus corpuscles,—which are in reality white blood-corpuscles,—which affects more or less the entire thickness of the cornea. This is due to the disposition of the leucocytes to move towards the place of the greatest concentration of the exciting substance, but as they are making their way towards the microbic area, stimulated to movement by the slighter concentration of the poison, they fail to reach it, because whilst still at a distance their movements are paralysed through the intensity of the toxic action and the cells have perished. We thus find an explanation of the central necrosis in cases of septic inoculation of the clear ring which surrounds this area and which is saturated with the poison, and of the opaque purulent area formed by dead leucocytes. The lecture is highly suggestive and reflects great credit on Professor LEBER.

## Annotations.

“Ne quid nimis.”

### VITAL STATISTICS OF LONDON.

In view of the increasing importance of and interest in the health of London, we publish to-day the first of a series of monthly articles dealing with the vital statistics of the metropolis, with special reference both to sickness and mortality in each of the forty-one sanitary districts of London. The returns of notified cases of infectious disease and the mortality in each of these sanitary areas are published in a table specially compiled for THE LANCET; and in order to render the information more valuable for comparative purposes the sickness and mortality rates in each district have been carefully calculated on populations based upon the recent census. The populations of these areas are now accurately known, and as the mortality figures in the table relate to the deaths of persons actually belonging to the various sanitary districts, the rates based upon them are therefore trustworthy and serve to show the true mortality in the various sanitary areas. The progress of any epidemic can be readily traced, both as regards its prevalence and its fatality, in different parts of London.

### A TEACHING UNIVERSITY FOR LONDON.

THE Royal Commission which is now sitting, after having heard a considerable number of witnesses dealing with various secondary points, is now approaching the crux of the whole question. During the next week representatives of University and King's Colleges, of the Royal College of Physicians—the Royal College of Surgeons having already been heard—and of the London medical schools will give evidence. We would remind our readers that whilst the higher education in London is of the gravest importance and every method of improving it merits the fullest investigation, the practical question of how London medical students are to obtain degrees on terms equivalent to those on which such degrees are granted elsewhere must not be left out of consideration. A University which cannot solve this difficulty must obviously fail from want of support by the medical profession. Surely if every capital in Europe except Constantinople and London has a local Teaching University with power to grant degrees to its students, there is no reason why London should not wipe out its reproach. The present University of London is a cosmopolitan examining board, nothing more, nothing

less, and it does its work excellently. It is as far divorced from all connexion with teaching as such an institution can possibly be, and it is therefore easily intelligible why teachers have risen in revolt against it. There are several practical points which must be carefully considered. Three schemes apparently have some support and of these two are old and one is new. The old schemes are those embodied in the proposals of the Senate of the University of London and in the Charter for a Gresham University passed last year by the Privy Council, but defeated in the House of Commons. The desirability of a single University in London is evidently an important consideration in the minds of many who have given evidence or have written articles on this subject. It is clear, however, to us that the existing University, with its traditions, its freedom from local influences and its high standard for degrees, can neither so change itself as to become a local Teaching University nor introduce into its constitution the necessary changes which would allow it to perform such duties. The Gresham Charter had the advantage of being a compact scheme, federalising the two teaching colleges and the ten medical schools whilst it presented no obstacle to their fusion for purposes of scientific teaching and allowed of every facility being given for the appointment of special professors to give instruction in the higher subjects wherein they had made original researches or in which they had attained special eminence. The new scheme is put forward by an "Association for Promoting a Professorial University for London." In this the federal principle is objected to and a centralised scheme is advocated. The leading propositions are thus laid down: "1. The University to be governed by a Senate composed of the professors and of a certain number of laymen to be nominated by the Crown. 2. The professors to be nominated in the first instance by the Crown, but afterwards by special standing boards of experts appointed for that purpose by the Senate. 3. The University to have power to absorb existing institutions of academic rank in London, due provision being made for protecting the interests of the present teachers in such institutions and for preserving the character of special trust funds. 4. The University to have the power of appointing readers and lecturers, either to supplement the teaching of the professors or to deliver graduation or other courses of lectures within the metropolitan area. 5. The degree examinations to be conducted by the professors of the University, acting in conjunction with other examiners to be appointed by the Senate; and no candidate for a degree to be admitted for examination without having attended the lectures of the University teachers for a prescribed period, which shall not be less than two or more than four years." It is further suggested that the medical faculty should be placed on a basis essentially differing from that of the other faculties. The scientific education of the medical student would apparently fall into the hands of a single professor in each subject and his assistants, and it is by no means clear whether sciences such as anatomy, physiology and pathology are to be included or whether the preparatory extra-professional sciences of biology, chemistry and physics are embraced in the scheme. In either case the powers asked for are too large. The number of medical students in London is so great that a centralisation such as is asked for would be deplorable. Three or four competing institutions would be the smallest number even for scientific training that we could recommend for London, and with regard to clinical instruction, provided the amount of clinical material were sufficient, the greater the number of influential and active teachers, the more advantageous would be the result to the student of medicine. There is truly a waste of teaching power in the metropolis, but even this is better than the possibility of a stagnation on the part of the professoriate and an indifference to the daily requirements of the medical student owing to research monopolising the teachers' attention.

We fear that a Senate appointed by boards of experts, without regard to teaching institutions and without regard to the ordinary teachers, could only tend to such an unfortunate result. The power of absorbing existing institutions—e.g., medical schools—can only have been asked for by idealists and not by persons who have an adequate knowledge of the various institutions interested in this question. Those engaged in medical and other sides of technical education must at once see the difficulty of agreeing to such a proposal for a city the size of London and will be sure to oppose its adoption by every means that is in their power. It is a worthy ideal, but considering the immense number of institutions which in many ways educate up to a University standard such a centralised scheme can only exist in "cloudland."

#### CHOLERA PROSPECTS.

IN so far as European cholera is concerned the centre of interest now lies in and around Paris, and the urgency of the question is considerably accentuated by the fact that official records as to the "choleraic"—so-called—prevalence in the suburbs of the French capital suddenly ceased three weeks ago and that their cessation has been synchronous with the highly suspicious circumstance to which our special correspondent drew attention last week and on which in our present issue he again comments strongly. For considerably over a month an epidemic has been going on in the vicinity of Paris which is attacking adults, which has definite characteristics of cholera, which is, so far as can be judged from the statistical information that transpires, as fatal to those attacked as many an epidemic of Asiatic cholera, and concerning which all official announcement has either suddenly ceased or is limited to such statements as the one made by Mons. Laubet, the Prime Minister, to the Chamber of Deputies on the 12th inst., to the effect that all necessary hygienic measures are being taken. So far as news has been forthcoming it is to the following effect. Diarrhoea of a very fatal character prevailed in some of the suburbs of Paris, especially included in the loop of the Seine to the west of the capital towards the end of May and early in June. On June 23rd twenty deaths had just occurred from so-called cholera nostras, Nanterre, Suresnes, Puteaux, and St. Denis being effected. By July 1st the epidemic had since its commencement, caused 159 deaths. Then came more detailed news as to the number of deaths in the various suburbs, and in new places attacked such as Aubervilliers, Quatre Chemins, La Corneuve, Courbevoie, Asnières, Clichy, Rueil and Colombes; but it was announced that Paris itself within the fortifications remained free. By July 4th fresh places such as Levallois and Gennevilliers were attacked. Next day ten fatal attacks were announced, and Neuilly was added to the list of localities infected. On the 6th and 7th there seems to have been a marked increase in the number of attacks, and besides this it was announced that between July 1st and 6th as many as 37 cases out of a total of 68 had terminated fatally. This in itself is sufficiently alarming for a diarrhoeal disease in Europe and in the minds of many it mattered little what qualifying adjective was used to designate this "cholera." Argenteuil and St. Ouen were now also attacked; indeed, the disease was reported to include twenty-four villages. On July 10th it was reported that Paris itself had become involved, although it was difficult to understand to what extent, owing to an apparent confusion between cases and deaths. At Aubervilliers four deaths took place on the 11th inst. This information cannot pretend to accuracy, for owing to the official silence it has had to be gathered from the ordinary public press. Whatever its source, it is evident that the Local Government Board look upon the intelligence, combined with the ominous silence referred to, as justifying the immediate exclusion of rags from France. Some, indeed,

reached Folkestone under such suspicious circumstances that the President of the Board issued a special order prohibiting their being moved inland; and since then a general order prohibiting the importation of all rags from France has been published in the *Gazette*. Evidently the authorities at Whitehall regard the state of affairs around Paris with the gravest suspicion; and everyone must admit that circumstances such as we have detailed are especially serious at the present season of the year. Accounts from eastern Europe are also very disquieting. Cholera continues to extend both in Transcaucasia and in a north-westerly direction from Astrakan and Baku. Perhaps the most serious matter in prospect is the intended fair at Nijni-Novgorod commented on in another column, for cholera has since our last report spread further up the Volga to Simbrisk, and thence to Kazan. Cases are also alleged to have occurred in the province of Kostroma to the north of Nijni-Novgorod. The Local Government Board have also issued an order prohibiting the importation of rags from all ports of the Black Sea and the Sea of Azov, as also from all ports of Turkey in Asia. The order takes effect at once. Pending the further development of the present state of affairs sanitary authorities everywhere will do well to remove all causes tending to pollute air, water and food.

#### OCTOGENARIAN PREMIERS.

WE can only speak at present in the singular number. So far as our knowledge of English history in this century and the last goes there has only been one octogenarian premier—Lord Palmerston—who died at his post in his eighty-first year. Several of our eminent statesmen in this century—not one in the last—who had in their time been Prime Ministers attained to this longevity. Henry Addington (Lord Sidmouth, son of Dr. Addington) died at eighty-seven, the Duke of Wellington died at eighty-two, Lord Grey at eighty-one, Lord Russell at eighty-six; but long before their decease they betook themselves to that “blest retirement” which the poet tells us is such a “friend to life’s decline.” We are no politicians, but we cannot be insensible to prodigies of power at fourscore. In this sense we regard with keen interest the recent mental and physical feats of Mr. Gladstone in his Midlothian campaign. He has already “beaten the record,” and if he is to be again Prime Minister of England we shall regard the achievement as one of which the English race may be proud. Such a statement involves no medical approval of men even of Mr. Gladstone’s strength engaging in political strife at eighty-two. But from a physiological point of view such power and pluck can only excite admiration, and we heartily hope that they may suffer neither harm nor discredit by the experiment.

#### THE CASE OF MR. WALTERS OF CHELTENHAM.

WE publish in another column resolutions of the Poor-law Medical Officers’ Association relative to the suspension of Mr. Charles A. Walters, medical officer of the second district of the Cheltenham Union, an appointment which he had held without complaint or fault for the long period of thirty-eight years. The matter is of still more sad interest, as Mr. Walters died on the 8th inst. The case is a very simple one. Even in its issue there is nothing serious save in its bearing on the unfortunate medical officer. The facts are as follows: A little girl came to Mr. Walters on a Sunday morning, April 3rd, at 11 o’clock with a note from her mother requesting him to see her sister. He asked if she had brought an order from the relieving officer and she said no. Mr. Walters then said “mother must send me an order or come and see me and tell me what is the matter.” The relieving officer was so near that he could be communicated with in half an hour. Meantime Mr. Walters suggested that her mother might give the sister a dose of castor oil. In the

evening, at nine, a Mrs. Robinson called and demanded Mr. Walters’ attendance in his capacity of medical officer *without an order or relief ticket*. She negatived the idea of his attending in any other capacity by stating that she would call in another doctor—a course the mother would seem quite able to have taken, seeing that within the last twelve months, since the death of her husband, she had received over £100 from benefit societies and had, while receiving a weekly grant from the Cheltenham guardians, £30 deposited in the savings bank. On calling next day to see if an order had been obtained Mr. Walters found that the child had been removed with a very mild attack of scarlet fever, from which in a month it had practically recovered. Such is this case. For declining to attend without an order Mr. Walters was suspended by the guardians and “severely censured” by the Local Government Board. We do not remember to have heard of a case where such dire punishment was meted out to a medical officer for doing what was certainly within his right and even his duty. It is undeniable that the mother of this child was able to pay a medical man and that she sent no order to Mr. Walters to attend in his capacity as medical officer. For declining to do so this faithful servant of thirty-eight years’ unblemished character is censured and suspended. We cannot admit that the mere suggestion of a dose of castor oil amounted to an “acceptance of responsibility” for the case, on which theory the Local Government Board founds its censure. We look to the Local Government Board to defend medical officers, and we have had pleasure often in recording that the Board has stood by them. But in this case there seems to have been a terrible failure of duty. Instead of censuring the guardians for giving relief to a person receiving £100 in a year, they censure the medical officer for requiring legal proof of her claim to be treated as a pauper. We cannot defend such action in a Government department, and if unexplained and unatoned for we prognosticate injury to the service. Medical officers under the Local Government Board have their rights as well as their duties. We heartily support the action of the Poor-law Medical Officers’ Association. Nor do we think they should be left alone to protest against such treatment of a medical officer of thirty-eight years’ standing. The Corporations of the profession should join them and claim for Poor-law medical officers the same justice that they would claim for medical officers of the Army or Navy. We commend this very hard case to the consideration of the Presidents of the two Royal Colleges, unless, as we venture to hope, the Local Government Board and the guardians will reconsider their judgments.

#### SCHOOL CHASTISEMENTS.

SOME grown persons would seem to think that there is no true place for chastisement in a system of education. Such at all events is our impression of those, and there are many parents among them, who regard an ordinary beating given in school as almost an indictable form of assault. People of this kind have evidently forgotten the singularities of their own wayward youth, or perhaps their lives knew only a genial and untroubled springtime of good conduct. In neither case can their judgment be relied upon to form a rule of discipline for the guidance of school teachers. The bad boy will continue to deserve, and to repay with better behaviour his needful thrashings, and even the good boy will sometimes err and will profit by corporal reproofs. The truth about physical punishment, we may take it, is that it is indispensable—an evil perhaps, but a necessary one. It must be borne, but in order to attain success with the least possible amount of injurious friction it must also be regulated. There must be no impulsive pulling about, no random strokes with the hand or the ruler, no ear-boxing with its probable sequela—the ruptured tympanum. The head should never be struck, not even slapped. We may say the same of the

body, but for one most tender but safely padded prominence which appears to mark the naturally appointed seat of childish affliction. We need hardly emphasise the importance of guarding jealously against all displays of temper while inflicting punishment. No doubt this is difficult with refractory children, but such a degree of self-government as will enable parents or teachers to avoid the angry moment is nevertheless requisite for success. A case occurred lately which illustrates this point. It was that of a boy who was beaten about the back and hand the day following a school misdemeanour. Singularly enough, he injured his head next day, and being at the time in poor health, though believed to be well, he died in a week from tubercular meningitis. At once his teacher was blamed; but proof being brought that the chastisement inflicted was deliberate, orderly and proportionate, though the means employed were not quite regular, he was entirely exonerated at a subsequent inquest. It would indeed, in many cases, render the duties of a schoolmaster as barren as difficult if he were not allowed a reasonable freedom in physical correction. The possible occurrence of such incidents as the above must, however, impress what we have said as to method in its application.

#### "CURES" FOR INEBRIETY.

THE special report of the meeting of the Society for the Study of Inebriety, on the 5th inst., which we published in our last week's issue, shows very clearly how necessary it was that we should give the profession and the public a timely warning against these secret cures. Dr. Keeley was unable to attend the meeting. Dr. Usher of Melbourne gave details of the method in which the so-called cure had been worked at Dwight, U.S.A., of the immense sums spent in advertising the institution and the cost of the preparation used—viz., thirty-six shillings for two bottles. Further, Dr. Norman Kerr laid before the meeting an analysis stating that the preparation contained neither gold nor chlorides, but 6 per cent. of sugar and 27.55 per cent. of pure alcohol. We quite agree with the members present that "so-called 'cures' for inebriety, the composition of which is not disclosed, are unfit to be commended by honourable members of the medical profession." Inebriety is a disease of which the treatment is as well known to the profession as is that of morphinomania or any similar habit, and it is only by legitimate and open treatment that it can be cured. There is no patent remedy for it, nor is there ever likely to be. Unfortunately, the unhappy sufferers and their friends are always asking for a specific and so they readily become the dupes of some ardent and unscientific believers in a method, or, worse still, of those who trade on their weakness.

#### "ELECTION FEVER."

It may not be inopportune during the turmoil of the general election to call attention to some of the dangers attending ill-regulated enthusiasm and irrational excitement. This appears to be the more necessary as already several fatalities attributable to these conditions have been reported. In the one case an elector died suddenly on the declaration of the poll, in another suicide is stated to have been the more tragic consequence, and yet another died through the excitement of the election. Danger under these circumstances is naturally both physical and moral and in some instances these causes are doubtless combined. Irregular and injudicious meals and irregular and insufficient rest are ever fruitful causes of that silent sap of energy which at the supreme moment causes it suddenly to fail, and a weak heart may then as suddenly cease to beat, or flicker out in futile palpitation. If to such purely physical dangers be added the still further strain of persistent anxiety, and its frequent consequence, defective sleep, it is not difficult to appreciate the unexpected loss of that calm control of both body and mind

which flows from the presence and consciousness of a reserve of force. To indicate these causes is not only to point out their natural effects, but also, to reasonable men, the lessons they convey. To those engaged in the work of the elections personal hygiene of the most careful order is of the first importance. Regularity in the storage of force and care and calmness in its expenditure are the secret of many a victory. "Those who strive in the games are temperate in all things," and the game of a contested election tries both mind and body severely. Nervous constitutions, wrought to a high pitch by the eloquence of party leaders or by the impulses of self-interest, are specially liable to sudden catastrophe, and it would be well for all such to remember, like one of Bulwer Lytton's characters, that the country has survived many unparalleled crises, and will yet survive many more quite as unprecedented. Moreover, to aggravate the causes of agitation by importing further sources of interest and unrest, such as betting on the issues involved and in other ways working up to fever heat the political furor, is very unwise in excitable persons. It is to point out these self-evident considerations which, nevertheless, are too apt to be forgotten at times of public excitement, that we have deemed it our duty to call attention to this matter.

#### APPARENT DEATH IN CHOLERA.

THE approach of cholera is already bringing much disquietude to the nationalities of Southern Europe, particularly to those who people the Mediterranean shores. The Italian, French and Spanish ports have on each former descent of the scourge suffered severely, all the more that in their conscious neglect of sanitary precaution their authorities invariably lose their heads in presence of the invader and attempt to atone by a few days' feverish energy for the culpable remissness of years. But there are special causes of the uneasiness, not to say positive panic, which the slightest hint of the advance of cholera arouses in those populations. Their custom of allowing but a few hours' interval, sometimes hardly a day, to elapse between decease and burial has on the occasion of increased mortality from epidemics induced certificates of death to be prematurely given, with the horrible result that apparent corpses have come to life on their way to the tomb or the crematorium, and with the necessary inference that not a few must have been buried or cremated when the vital spark, so far from being extinct, might still have been kept alive. The great Tuscan pathologist Pacini some thirty years ago published a memorable pamphlet on "La Morte Apparente della Colera" and having instanced a number of cases in which the seeming corpse had been snatched from the very brink of the grave he proceeded to give rules by which even in collapse the apparent victim to cholera might be resuscitated. Among his prescriptions that of the intravenous injection of bay salt, as suggested and practised in 1832 by Dr. James Macintosh of Edinburgh, held a prominent place and by this means, particularly in the cholera visitations of 1877 and 1884, the restoration to life of many duly certified as dead was just in the nick of time effected. In the latter year, however, a remarkable and extremely painful instance of the all too tardy resort to the practice occurred in the person of a distinguished Genoese physician who, having overworked himself in the public cause during the epidemic, was himself struck down just when it was in full retreat. Every care was bestowed upon him, but he rapidly sank into collapse and within forty-eight hours he was thought to be, and certified as, dead. Burial arrangements were in progress and the family, sitting disconsolate in a room adjoining that in which he was laid in his shroud for burial, were expecting the arrival of the undertaker every moment, when, to their mingled horror and delight, the door was feebly opened and the apparent corpse presented himself and, in a voice scarcely audible from

weakness, remonstrated with them for having left him so long unattended. Instantly they conveyed him back to bed and employed, under the best professional advice available, every means that could be imagined for his rescue; but in vain. He died a few hours afterwards of cardiac failure. The case was much commented on at the time as a typical example of what might occur on the strength of death certificates prematurely given, and so Pacini's method was reapplied with enhanced vigilance on every cholera patient who had reached the stage of collapse. The epidemic ran its course; the panic and the vigilance born of it disappeared, till now, when cholera is again within measurable distance of the Mediterranean seaboard, Pacini's name and practice are once more trotted out. The Southern populations, however, must surely have learned by this time that prevention is a better safeguard than cure, be it as ingenious as it may, and that to leave their ports in a mediæval state of filth and neglect invites those cholera explosions that never occur on so sudden or so vast a scale in the more civilised harbour towns of the British Isles or of the Dutch and Danish coasts. With the experience of Naples and Spezzia still recent, sanitary rehabilitation must have made some way towards the protection of regions to which quarantine and "hygienic cordons" have ceased to give the security so long laid to their credit.

#### LONDON DUST AND REFUSE.

LONDON residents will be dismayed if they find they are required to burn the vegetable and other refuse which collects in their houses and if the dust collector receives instructions not to remove anything but dirt and ashes. The readers of the columns of the *Daily Telegraph* will find in it letters from "distressed" and "aggrieved" Londoners complaining that such is the case; the former states that his cook had informed him that the dustman would no longer remove any vegetable stuff; living in a flat, he had found it difficult, if not impossible, to burn it; the latter writes that the vestry's dustman had declined to take any vegetable refuse, paper or garden rubbish; that to burn this in the house would be prejudicial to the household, and that to burn it in the garden would create offence to the neighbours. We cannot but think that there must be some misunderstanding; it is reasonable for sanitary authorities to require householders to burn such matter as is practicable, but it is equally certain that local authorities must be prepared to relieve householders of their waste refuse. We do not suppose that sanitary authorities will be unreasonable in this respect. What is wanted at the present time is that a system of periodical removal of house refuse should be instituted in all parts of London and that houses should be provided with the proper receptacles for its storage for the short period which must intervene between successive collections.

#### THE EPSOM COLLEGE REPORT.

THE report issued for the present year by the Council of Epsom College makes out not only a strong case for generous support by the profession and the public of this most deserving institution, but also a record of advance made in the direction of securing public recognition which should encourage the friends of the school to take a very hopeful view of their prospect of shortly surmounting the difficulties by which they have been, by which indeed they still are beset. In the meantime these difficulties are very serious and it cannot be doubted that the highly creditable result which the Council are able to report has been reached only by dint of very determined and wholly unremitting labour on the part of those who are entrusted with the work of carrying on the school. During the past year it has held its own in comparison with kindred

institutions and shows a very gratifying list of academic successes. The amount of good which by its charitable and its educational work Epsom College accomplishes and the value of the service which in both respects it renders to the medical profession cannot well be overstated. Unfortunately it is only too easy to under-estimate them, and the neglect of which for many years the active supporters of the school have had too much reason to complain affords abundant proof of this proposition. We trust that this period of neglect has now passed away and that the newly awakened interest, which so largely contributed to the success of the biennial festival, is the herald of a happier time in the annals of the College. This quickened interest is amply justified by the success which has already been achieved under distinctly depressing conditions of work by an executive whose devotion to their undertaking is just beginning to be recognised. We trust that the time is not far distant when this institution will be regarded with fitting solicitude and pride by all the members of our profession. It will then flourish on a scale at present rendered impossible by the narrowness of its means, and we do not hesitate to predict that the skill and zeal which have rendered it at the present moment worthy to represent a great profession in its own department will under these more fortunate conditions place it in a position to receive by common consent the rank among public schools to which its connexion with the profession of medicine gives it a presumptive claim. Founder's Day will be held on Monday, July 25th, when the annual distribution of prizes will take place.

#### IMPROVEMENT SCHEMES IN LONDON.

THE London County Council, at their meeting last Tuesday, resolved to contribute one-half of the cost of a scheme for the improvement of an unhealthy area in Shoreditch and themselves to carry out an improvement scheme in Mill-lane, Deptford, to which the sanitary authority will contribute one-half the cost. The Mill-lane area comprises fifty houses, in addition to which are eight registered lodging-houses and other premises. It is proposed to erect improved lodging-houses in place of those which are to be demolished. This area is now occupied by very poor Italians, who sell ice-creams in the summer and in the winter perambulate the metropolis with barrel-organs. The outbreak of enteric fever in Deptford and Greenwich last autumn was found on inquiry by the Council to be caused by the distribution of ice-creams from this locality. The estimated cost of the improvement is £39,500.

#### THE REPRESSION OF INFANTICIDE.

A RECENT meeting of the Society for the Prevention of Cruelty to Children is worth recording, if only for the practical discussion of the question of child life insurance, which occupied a prominent place in its agenda. It was generally agreed that the proposals contained in the Government Bill on Friendly Societies were quite inadequate to deal with this matter. As a measure it was distinguished as much by its friendliness towards insurance companies and insuring parents as by its comparative inattention to the weal or woe of the helpless children. The following suggested amendments ought to be borne in mind by any and all who have at heart the best interests of the latter. First, as regards registration, it was proposed that steps should be taken to secure the efficient notification of every case in which a burial policy was taken out in respect of a child, that death (if it occurred) should be officially noted, that agents should be registered, that the sum insured should be no more than sufficient for burial (about £1), and finally, that this should be granted only on receipt of satisfactory proof respecting the actual nature of the child's last illness. The very necessity for burial insurance shows a want of adapta-

tion in domestic money matters. It were certainly preferable if by the independent exercise of homely thrift any such necessity could be done away with. Where this is impossible and the alternative method is employed it must in mere justice to the life involved be guarded by the rules above-mentioned. We would therefore ask for these the careful attention of the new Parliament. A further suggestion was brought forward at this meeting—namely, that persons having charge of even single nurse children should be subject to efficient supervision. We have long advocated such an arrangement. It aims at the root of the baby-farming evil and it must, if carried into effect, exercise a wholesome influence in its repression.

#### POISONOUS ICE CREAM.

SINCE Dr. Vaughan reported ice creams as containing most deadly irritant poison medical officers of health have been quick to detect any poisonous agent in this substance. Dr. George Turner, acting for the Public Health and Housing Committee of the County Council, has been able to demonstrate that in certain parts of Mill-lane, Deptford, the ice cream made by Italians is prepared under conditions which he deems to be favourable for its contamination. We are glad to see that the committee, instead of deferring the matter by appealing for special legislation, have expressed the opinion that the proper remedy for the condition indicated is the efficient application of the general provisions of the Public Health Act to places in which food is prepared for sale and not the acquisition of further powers dealing with articles designed for consumption. If these powers are not sufficient an enactment must be obtained, but if Dr. Turner's report is carefully studied and the points to which he draws attention are mastered by the authorities, they will find that they have full powers to act where ice creams are being manufactured in premises in which people are living under unwholesome conditions. The general powers under the Act are very far reaching, and if properly put in force should cover all irregularities and provide for bad hygienic conditions in all places where articles for human consumption are prepared or manufactured. Typhoid fever is at present too rife to permit of any factors, however doubtful, involved in its spread being ignored.

#### HONOURS TO A PHARMACOLOGIST.

ON March 29th, 1792, was born, at San Miniato, in Tuscany, Gioacchino Taddei, who rose to be one of the lights of the Florentine school, in which for many years he held the chair of Pharmacology. In the Arcispedale di Santa Maria Nuova he taught the practice of his subject to successive generations of students and contributed by precept and example to raise that branch of the profession to an efficiency unsurpassed in any other province of Italy. He sat as one of the Tuscan group in the Italian Chamber of Deputies, where his services as a wise and liberal legislator, particularly in all questions relating to the public health and to the higher education, professional and lay, procured his subsequent promotion to a seat in the Senate. Taking these facts into consideration, the "Associazione Chimico-Farmacologica Fiorentina," in coöperation with the Communal Council of Florence, will at an early date cause to be unveiled on the façade of Professor Taddei's house a memorial tablet setting forth his signal contributions to science, to public health, and to his country's unity and independence. The bestowal of such honours is a frequent and commendable practice in Italy. No doubt it is sometimes abused. Monuments and memorial tablets have from time to time been erected not so much to honour the "illustrious obscure" as to gratify the self-advertising ambition of organising committees and their presidents, whose activity, culminating in the ceremonial proceedings and the inevitable

banquet, with its opportunities of speech-making, fructifies in little else than a confirmation of the impression that "Italians are a carnival people." But there can be no doubt as to the propriety of unveiling a tablet to Gioacchino Taddei. His scientific eminence would of itself justify the step, even if he had not been an exemplary citizen and an intrepid patriot in days like those of 1849, when espousal of the national cause meant social ostracism, confiscation of means, exile and not seldom death itself.

#### THE MEDICAL OFFICER OF HEALTH, NEWTOWN, MONTGOMERYSHIRE.

OUR attention has been directed to the decision of the Newtown Local Board to elect a medical officer of health in place of the gentleman who has recently held that office. We have received evidence of the esteem in which Mr. Palmer is held by those who have had the opportunity of forming an opinion of his work. The appointment he holds is an annual one, and it is open to anyone who may take exception to the action of this officer to seize the occasion of his re-election and to endeavour to introduce another medical man into the office. The circumstances under which the Newtown Local Board have been led to adopt this course deserve the investigation not only of the profession but of the public, for the public cannot be well served if medical officers of health feel they cannot be re-elected if they show the least independence either in the performance of their duties or in the ordinary conduct of life. In the present case it was decided to advertise the office only upon the casting vote of the chairman.

#### CHOLERAIC DISEASE IN FRANCE.

IT is interesting to learn that Dr. Dujardin-Beaumez speaks of the malady that is now alarming Parisians as a form of cholera fostered by bad drinking water and the insanitary conditions that prevail in the environs. Although unwilling to call the disease cholera, he describes it as of Asiatic origin, arriving in France from Persia by the Caspian Sea, making its first appearance at Nanterre at the end of March and subsequently spreading to Asnières, Neuilly, St. Denis, Aubervilliers and Clichy. Later accounts speak of this malady as occurring also at Suresnes, Courbevoie and Colombes. What is obviously greatly needed is an inquiry into the whole circumstances of the disease, such as the Local Government Board makes in England whenever the prevalence of any malady demands investigation. The suburbs of Paris are, it is said, unable to provide themselves with satisfactory water-supplies and hence water from the Seine and Marne are utilised to make up for the deficiency of other supplies. The inhabitants of these localities have a right to know whether the water is to blame. Cholera in Paris may lead to the introduction of the disease into England, though with us there is less cause for alarm. Still, all English water-supplies are not above suspicion, and there is no community so perfect from a health point of view as not to require the earnest attention of the sanitary authority.

#### THE POLLUTION OF THE MERSEY AND THE IRWELL.

AT a meeting of the Mersey and Irwell Watershed Joint Committee, which was held last week, the chairman (Mr. J. T. Hibbert), after congratulating Mr. Hulton, the clerk, on the success which had attended the passage of the Bill through Parliament, commented on the action of a representative of the Local Government Board when the Bill was brought before a committee of the House of Commons and stated that, while he thought some of the control by this Board was useful, he did not think that an important joint committee like that dealing with the whole watershed should be treated as children. He further regretted that any au-

thority in the watershed and represented on the watershed board should have opposed the Bill. He then stated that twenty-nine authorities had sewage works in operation, but that they varied in effectiveness. Some required alteration. In twenty-three places there were no schemes in operation and on twenty of these twenty-three authorities notices had been served. The two months' notice had now expired and he thought it desirable that further action should be taken against them at the next meeting. The figures he had submitted dealt only with urban authorities—the rural had in nearly every case taken some action. Mr. Armitage gave notice that at the next meeting he would move that action be taken against those authorities which had not adopted any scheme.

#### ELECTRICITY ASTRAY.

AN accident to an electric lighting main in Walbrook, E.C., appears to have recently occasioned some merriment to the dwellers in those parts. We cordially congratulate them on having escaped any more serious consequences than those which provoked their mirth. It seems that through some unexplained failure of the insulator of an electric-lighting main a metal shop front became charged with wandering electricity and passers-by discovered that by touching it with their hands they could experience the delightful inconvenience of an electric shock. The circumstance that this luxury is in the minds of most people, and particularly of most street urchins, associated with festival occasions and penny fees no doubt invested the unpriced supply in Walbrook with an added charm. Happily, the amount of current obtainable seems to have been inconsiderably small; but seeing that a metal shop front in connexion with an electric-lighting main might easily become a greater source of peril to unwary passers-by than an uncaged tiger, the story of this mishap is calculated to give the reader of a serious turn more food for reflection than is altogether pleasant. Fortunately, it is not possible that such an accident should happen without serious fault on somebody's part, and although the London public seem to have taken the matter with a light heart, we hope that those whom it most nearly concerns will make a point of exacting the full penalty for a flagrant default, be it whose it may—*pour encourager les autres*.

#### THE CHOLERA IN KASHMIR.

SOME further particulars of the cholera in Kashmir are to hand in the form of a letter from Mr. A. Neve, the senior medical missionary, who when the epidemic commenced was working single-handed, as his brother, Dr. Ernest Neve, had gone with a party of Moravian missionaries to Ladakh. He had, however, a valuable native helper. As soon as the epidemic became at all pronounced the British resident and all the European visitors took flight to Gulmarg, a hill sanatorium some thirty miles from Srinagar. Mr. Neve and his assistant carried out as systematic a visitation in the city as was possible, but little could be done either in the way of sanitation or of medication, as the cases were rarely seen during the first few hours, when drugs are really valuable. The hospital was as far as possible cleared out, the patients being sent away to their villages lest in their weak state they should contract the disease. "I got up very early," continues Mr. Neve, "and ride to the bazaar. The head man of each district then comes and escorts me to the new patients in the neighbourhood. Many of the houses are two- or three-storied and one has to climb up and down the most tortuous stairs, usually very steep and the ceilings very low, so that my thick sola topi has been almost smashed to pieces. The people all crowd round the unfortunate patient. A well-known man will have twenty or thirty neighbours sitting round him and the women do not reserve their wails for the dead, but beat their breasts and

tear their hair and scream 'Hai, hai, wai, wai' if anyone is badly attacked. .... For a time there seems to be no 'purdah' and no class is specially inaccessible. In fact the well-to-do Hindus seem quite as willing to receive me as any others. In many cases one can do little; in others one can turn the scale. But although a few lives here and there have been saved I think the moral effect of our work is more important. The people well know the apathetic selfishness of their co-religionists and they see the missionaries and ladies as well as others going about trying to relieve suffering." Mr. Neve's assistant succumbed to the disease, though after transfusion he rallied for a short time. The Indian Government have deputed Surgeon-Colonel Harvey to make a searching inquiry into the epidemic and he has taken up his quarters in the mission house with Dr. Ernest Neve, who has returned, Mr. Arthur Neve going out into the villages where the cholera, after having abated in the city, was becoming rife.

#### ENTERIC FEVER AT NORTHALLERTON.

ENTERIC FEVER still prevails at Northallerton, but, as we anticipated, the Local Government Board do not see any reason for sending a medical inspector to investigate its causes, those causes being known in advance to the local authority. Mr. Lumley again tells the local board that the further incidence of the disease goes to confirm his view that it is due to polluted water. Unfortunately the account of the proceedings of the local board does not contain any statement as to what is being done; indeed, the only action recorded is a proposal that the board should form itself into a committee to further consider the outbreak and the means which should be adopted to stop the spread of the disease. It is, however, to be hoped that all suspicious water-supplies have been stopped and that a wholesome supply is being delivered day by day, by water-cart or otherwise, at all houses where the local supply is liable to contamination.

#### A PRESIDENTIAL ADDRESS.

THERE lies before us a copy of an important and highly interesting document which should be available for every member of the profession, for it deals with topics of more than local interest. It is the address of the President of the Royal College of Physicians delivered to the assembled Fellows on the occasion of the close of his year of office. We are unfortunately restrained from discussing its contents and especially its exhaustive treatment of the movement for a new or reformed University in London by the superscription on the title-page "private and confidential." Is this also one of the "secreta Collegii"? Surely it cannot be so intended. Incidentally we may remark that the "secreta" have of recent years been unusually numerous, and we cannot help speculating whether the bond of union that has obtained between this College and the sister institution in Lincoln's-inn-fields may have had a tendency to deprive the proceedings of the College of Physicians of a publicity which in these days ought to be the rule and not the exception. Apart from the general question, however, it does seem foolish and unworthy of the College to require its President to restrict the circulation of his address to a small circle, and whilst we are dealing with this specific instance we may perhaps express a natural regret that the previous addresses of the present occupant of the presidential chair and those of his much-revered predecessor have never been published. They are of permanent value and should not be suffered to lie neglected in the College vaults. For without doubt they contain words of wisdom and the teachings of ripe experience which might exert the best possible influence upon the profession, not only in the present day but in years to come. The London College of Physicians occupies such an eminent position among the medical institutions of the empire that it is its bounden duty to lose no

opportunity of inculcating the principles it represents and the ethical standard it maintains. It could not better promote these aims than by publishing the annual addresses of the leaders of the profession whom it places at the head of its affairs.

#### SMALL-POX IN YORKSHIRE.

SMALL-POX still hangs about some of the Yorkshire towns and villages. During the month of June Liversedge and the Doncaster rural district and some localities in the neighbourhood of Halifax were somewhat seriously affected. Mexborough is still suffering from the disease.

#### THE SCARLET FEVER EPIDEMIC IN LONDON.

A STATEMENT made at the last meeting of the managers of the Metropolitan Asylums Board is entirely in the direction of the caution which we uttered in our leading article of last week as to the extent to which scarlet fever is prevailing in the metropolis. The chairman explained that the incidence of the 2247 cases under isolation in the Managers' hospitals amounted only to one case per 2000 of the 4,250,000 people in London. And even if we assume the total number of patients to be double that in hospital, the rate of attacks would only be 1 per 1000. The death-rate, as we intimated, is by no means alarming at the present moment.

#### THE MEDICAL MAGAZINE.

A NEW literary adventure in the medical world deserves a hearty welcome, when, as in the case of the monthly journal appearing under the above name, it is issued with the laudable desire to restrict the growing tendency on the part of lay periodicals to insert contributions on medical subjects in their pages. This magazine, which is produced in commendable style, has doubtless a mission to fulfil, and the contents of the first number are varied as well as interesting. There is a faithful and just tribute to the work and character of the late Dr. H. G. Sutton, one of the most remarkable physicians of our day from the pen of Dr. Donkin; an interesting sketch of the health conditions of Chester from mediæval times to the last century by Dr. Creighton; and some strong advocacy of the value of periodical medical literature in advancing medicine by Dr. Saundby. Dr. Maudsley writes on Suicide in Simple Melancholy, in which he conveys the impression that suicide is not out of the natural order of things, as we are disposed to regard it. Mr. G. H. De'Ath, the medical officer of health for Buckingham, does good service by drawing specific attention to facts of rural sanitation (or rather insanitation) which have come to his notice. Dr. Francis Warner contributes a brief paper on Mental Physiology; and there is an anonymous (presumably editorial) article on the Medical Profession and Practical Politics—an appeal to members of the profession, especially those retired from active practice, to share in political and municipal affairs.

#### CHOLERA AND CROWDS.

THE Russians are evidently greatly disquieted by the fear of the threatened epidemic of cholera and are taking the most active measures to prevent the spread of that disease along the lines of railroad. Cholera is advancing up the Volga. Of that there can be no doubt apparently, and it becomes a serious question as to what steps have been taken in regard to the approaching fair which, we are told, is to be held at Nijni Novgorod. The latest accounts would indicate that the official authorities in Russia have been very active in this direction of late, but whether the sanitary arrangements are of an adequate kind and commensurate with the occasion we do not know. The

authorities in India have had great experience of what occasionally happens at Hurdwar and other large religious gatherings and of the arrangements that have to be made to prevent an outbreak of cholera or limit its spread. A great deal of forethought and labour are expended in the way of organisation and preparation on such occasions, and arrangements are also made for the sudden breaking up of the religious fairs and dispersal of the pilgrims in case of need. When any epidemic is actually present or impending there must obviously be great risk attending the assemblage of a large concourse of people. Even if some of them did not bring the disease with them, the heat, fatigue, overcrowding, defective sanitary arrangements and difficulties connected with water-supply, are all adverse factors that have to be encountered. A commercial fair like that at Nijni Novgorod is, of course, on quite a miniature scale compared with one of the vast Hindu religious gatherings in India, but all such assemblages require great preparatory care in the way of sanitary organisation and arrangements. The truth is there is no short and ready way, no royal road to the prevention of the spread of cholera in a country by quarantine and cordons. The scale on which the attempt has to be made is altogether too large and the difficulties too great for it to be practicable to apply such methods. Sanitation on a large scale, a pure and good water-supply, efficient sewerage, cleanliness and wholesome dwellings are the only reliable safeguards against cholera. There is the seed and the muck-heap to be dealt with, and if the former cannot be destroyed the muck-heap necessary for its growth and development can be removed. An increased knowledge and experience have only confirmed the truth and given precision to the late Lord Palmerston's sagacious remarks on the subject.

#### RIGOR MORTIS IN ITS RELATION TO DEATH FROM POISON.

THE *Wiener Medicinische Presse* publishes a paper read by Professor A. Paltauf before the Association of German physicians at Prague on some experiments he had made to show the causal connexion between rigor mortis and deaths from poison. For the purpose of these experiments such poisons were used as were known to exert a certain influence on the muscular system, either by directly acting on the muscular substance or indirectly by affecting the nervous system. Amongst the poisons belonging to the first series curare always considerably delays the occurrence of rigor mortis. Amongst those acting on the central nervous system, strychnine, picrotoxine, camphor, and the salts of ammonium accelerate the occurrence of rigor mortis. This acceleration is still more increased by artificially prolonging the stimulation of the muscular system, but is again arrested on the occurrence of paralysis. Veratrine and physostigmine cause only a slight acceleration of the rigor mortis, but with caffeine and its chemical derivatives—the rhodan salts—this acceleration becomes considerable. To study the influence of the nervous system at the time of occurrence of the rigor mortis, Professor Paltauf divided the nerves and the spinal cord, with the result that the more a muscle had been stimulated by the poison the sooner was the rigor mortis observed, independently of its connexion with the spine, if such connexion existed. The reaction of the rigid muscles was in the case of many poisons, as has been generally believed, acid. Other poisons, however (such as camphor, ethyl-theobromine and the rhodan salts), gave, contrary to the general assumption, an alkaline reaction. This alkaline reaction affected, however, only the anterior portion of an animal in which after the poisoning the cord had been divided. The posterior part of the animal, in which the rigor mortis was delayed, showed the usual acid reaction until the alkaline reaction of putrescence took place. Where the reaction of the anterior portion of the animal was

alkaline it often became, after the reduction of the rigidity had passed off, neutral or slightly acid before putrescence once more made it alkaline. Division of a single nerve had the same result, and it was possible to cause either alkaline or acid reaction in the various muscles of one extremity by leaving the nerve entire or dividing it. Professor Paltauf also approached the solution of the question of the existence of a cataleptic rigor mortis. He found that the convulsive muscular contractions of an animal poisoned by camphor and suddenly killed by strangling led to immediate rigor mortis, and he therefore believes in a cataleptic rigor mortis.

#### THE COST OF HEALTH OFFICERS AT LEWES.

MR. J. G. BRADEN has resigned the post of medical officer of health for Lewes after a service which has extended over many years and which has been courteously acknowledged by the Town Council. Not only has that service been efficient, but it involved a period of great anxiety and responsibility when Lewes suffered in 1874 from its now historic epidemic of enteric fever due to insuction into water-pipes of infective matters during intermissions in the service. A committee of the council have recommended a new appointment at £100, but the subject has been referred back to them because some members of the corporation think £80 sufficient, and they quote other places which are comparable with Lewes in point of area and population in support of their contention. In one respect the comparison is inapplicable, for at Lewes it is to be part of the duty of the health officer to attend such patients at the isolation hospital as are not under the care of their own medical advisers. Even a few such cases will involve a large number of visits extending in each case over many weeks, and if the corporation were to set this service down at £20 a year it would probably be the least that could be offered for it. This would as a matter of fact place Lewes on a level with those towns where the medical officer of health receives £80 a year. There is another reason for dividing the total salary in this way. No repayment from the county funds is likely to be secured for the hospital attendance, for it is no part of the official duty of a health officer to attend patients anywhere. The repayment is certainly to be limited to the £80, which is regarded by some as sufficient for the services of the health officer as such.

#### MULTIPLE NEURITIS.

At the meeting of the Congress of Neurologists held at Baden-Baden a few weeks ago Dr. W. H. Gilbert read a paper on two cases of polyn neuritis which presented some striking features. The first was that of a high Government official, aged fifty-six, a member of a "very nervous family," and himself of irritable and hasty temper. In February, 1891, he had an illness thought to be peliosis rheumatica, in which he suffered great pain, followed by cutaneous anaesthesia and muscular paralysis of the extremities. He improved somewhat under electrical treatment and massage, but when first seen by Dr. Gilbert he was emaciated to an extreme degree. There was, in fact, general muscular atrophy, abolition of the plantar and patellar reflexes, whilst the nerve-trunks, which could be felt through the attenuated lower limbs, were the seat of painful nodular swellings. There was some loss of control over the bladder and rectum. Under treatment he improved slightly, so that he could walk better and gained a little in weight. An attack of diarrhoea, brought on by exposure to cold, rapidly reduced his strength and he died on July 9th. The other case related by Dr. Gilbert was that of a lady, thirty-two years of age, who, on Feb. 2nd, 1892, swallowed a large quantity of "Schweinfurt green" with suicidal intent. Prompt recourse to the stomach-pump and other measures averted a fatal issue, but then ensued great prostration and severe gastro-enteritis lasting four days.

Next followed symptoms of paralysis of the limbs with severe paroxysmal pains, especially in the right limbs, numbness of the fingers, sensation of cold, profuse sweating and insomnia. In this condition the patient came under Dr. Gilbert's care on April 3rd, when she could only move slowly and with great difficulty, and complained of stiffness in the legs and great weakness. The plantar and patellar reflexes were exaggerated and there was foot-clonus on the right side, but only moderate anaesthesia. This patient, who presented in a striking degree the effects of arsenical neuritis, entirely recovered. Dr. Gilbert remarked that in each of these cases the motor functions were more involved than the sensory.

#### DEATHS OF EMINENT FOREIGN MEDICAL MEN.

The deaths of the following distinguished members of the medical profession abroad have been announced:—Dr. Anders Georg Drachmann, father of the poet, Holger Drachmann. He made a great study of hygienic gymnastics and orthopaedics and of the hygiene of childhood. He practised medicine in Denmark till within a short time of his death. He was eighty-two years of age.—Professor Hermann Nasse, of Marburg, at the age of eighty-nine. In his earlier years he was assistant to the Professor of Surgery in Bonn, and from thence was invited to Marburg as Professor of Physiology, Pathology, and Veterinary Pathology. The two latter subjects he gave up after a few years, devoting himself entirely to physiology, and in 1879 he transferred the charge of the physiological laboratory to Professor Kuelz.

THE British Institute of Public Health have issued regulations for the conduct of their examinations for sanitary inspectors. There will be two examinations, the first preliminary, the second technical, held twice in each year, in April and October. It has been arranged that the first annual meeting of this institute shall be held in Dublin on Aug. 17th, 18th and 19th.

THE German Consul has officially informed Mr. Gerald Portal, the British Consul-General, that the German Government recognises the right of Great Britain as the protecting Power to regulate the sale of liquors in Zanzibar and has ordered German subjects to submit to the licensing system established.

WE learn from inquiries made at the Pasteur Institute in Paris that M. Pasteur suffered a fortnight ago from slight diarrhoea and colic. He is now, however, we are glad to state, well and able to resume his customary daily walks in the Park of Villeneuve.

AT the quarterly meeting of the directors of the Naval Medical Supplemental Fund held on the 12th inst., T. Russel Piekthorn, Esq., Inspector-General, in the chair, the sum of £70 was distributed among the several applicants.

DR. ALFRED HILL has accepted the presidency of the Birmingham branch of the Association of Medical Officers of Health. Dr. Hill was the founder of the Association, and its first president, sixteen years ago.

DR. GEORGE GORE, F.R.S., has been awarded a Civil List pension of £150 in consideration of his services to chemical and physical science.

OUR Paris correspondent telegraphs that no death from cholera had occurred in that city on Tuesday or on Wednesday.

REPORT OF  
The Lancet Sanitary Commission  
ON THE  
DRAINAGE OF SURBITON.

THE SANITARY AUTHORITY.

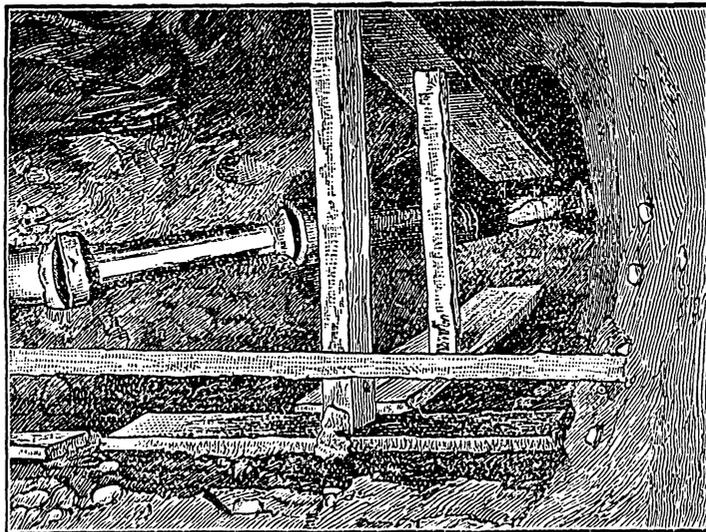

THE sanitation of Surbiton is under the control of the Improvement Commissioners, by whom are appointed a medical officer of health (Dr. Coleman) and a borough surveyor and inspector of nuisances.

THE MAIN DRAINAGE.

Most of the sewers consist of earthenware pipes which have been laid down during the last ten years; but we are informed that two or three of the old brick sewers still remain in use. The storm waters are carried by separate channels. Up to a recent date the sewers were ventilated by openings at the level of the road, but owing to complaints of nuisances arising from these ventilators several shafts have been carried from the sewers up the sides of the houses and many of the old road ventilators have been closed, with the result of abating the nuisance. The sewage of the town is carried to Kingston and is there subjected to precipitation by means of the A B C process, the effluent being subsequently run into the

statement of one inhabitant the house drain was not only not laid on concrete, but the individual pipes were uncemented, so that sewage was leaking through at every joint. The rain-water pipe was also untrapped and opened directly into the drain. In this house a case of diphtheria occurred and was the cause of the drain being examined. Another house was found to be in a condition somewhat similar. A case of acute dysenteric diarrhoea having occurred, the medical attendant suggested an examination of the drains, with the result that the house drain was discovered passing over a cesspool, the joints uncemented and leaking, and the sink wastepipe connected directly with the drain. The accompanying engraving is from a photograph of the drain of a house in which "much sickness occurred" and from which the family were ordered away by the medical man in attendance. It will be noted that the joints of this drain are open. We were also informed that a gentleman had offered to take a house in the neighbourhood on condition of the drains being satisfactory. On the drain being laid bare and tested with smoke and water the joints were found to be so defective that the inspector reported that the drain would require to be relaid. The other sanitary arrangements of the house were also condemned. This house had been built within the last two years. It was also stated that there are houses in Surbiton which have not been properly joined to the new sewers; but of this class we could not obtain an example based on sufficiently reliable evidence for the purpose of this report.

3. *Houses built before the passing of the by-laws of 1880.*—Examples of defects in the sanitary arrangements of houses

Thames. The Surbiton Improvement Commissioners pay the Kingston authorities for the disposal of their sewage according to the quantity treated, and we were told that in consequence of this arrangement only a certain amount of sewage is allowed to escape at the outfall, the rest being backed up in the Surbiton sewers during the night. It is said that as a consequence of this the air of Surbiton is frequently offensive in the morning. During our visits to Surbiton we could not detect any smell from the sewer ventilators in the road.

HOUSE DRAINAGE.

The code of sanitary by-laws at present in force in Surbiton came into use in 1880 and we shall best be able to describe the drainage of the houses by dividing them into classes, according as they were built prior or subsequent to the passing of these laws.

1. *Houses built in compliance with the by-laws of 1880.*—The drainage of these houses has been laid down according to the most modern plans, the house drains being outside upon concrete and provided with inspection chambers at the front and back of the drain. The sink, bath and rain-water pipes are all disconnected and cistern overflow pipes discharge outside. We had an opportunity of inspecting some of these houses and are satisfied that these points were all carefully attended to.

2. *Insanitary houses erected since 1880.*—Of these houses several have been brought to light recently. According to

of this class are naturally numerous. We personally inspected some of these houses and found them drained according to the old plan—soil-pipe inside and unventilated, pan closets, waste pipes not disconnected, and rain-water-pipes going straight into the drain. We found one of the worst examples of these houses to be in the following condition: A four-inch soil-pipe had fixed on to it a one inch and a half ventilating pipe; a single cistern supplied the closets and drinking water by a single pipe which divided into three branches; the closets were of the pan type, and the D trap of one of them projected for about four inches into the roof of the pantry. The sink waste was not disconnected, and the cistern overflow did not discharge externally. We have also been furnished with written reports of sanitary defects which have been detected in houses of this class during the past three or four months. These include soil-pipes inside the house, soil-pipes ventilated with one-inch pipe, unventilated soil-pipes, ventilating pipes made of zinc, drains passing under the house with leaking joints, cisterns outside the house and uncovered, rain-water-tank under the floor, with overflow into drain and no trap intervening, pan and container w.c. fixed direct to the drain with no trap, and waste-pipe from lavatory discharging into drain under w.c.

GENERAL REMARKS.

It must be admitted that the drainage of Surbiton, compared with that of other places, is fairly good; but it is evident from the instances adduced above that it is far from perfect.

The sanitary laws in force in Surbiton are excellent, and were they rigidly enforced during the erection of new houses would secure to the town an admirable system of drainage. We were informed that the duties of borough surveyor and inspector of nuisances are discharged by one official. There has been much dispute between one inhabitant and the Improvement Commissioners as to how his house came to be in the state in which it was found; and the solution of the difficulty has been by no means satisfactory.<sup>1</sup> As regards the houses built before 1880, their sanitary defects must be remedied either by tenant or landlord; or failing these, by an appeal to the sanitary authority on a nuisance arising from them. On turning to the report of the medical officer of health (Dr. Coleman) for 1891 we see that the total death-rate is returned as 13.5 per 1000, the death-rate from zymotic disease being 1.1 per 1000. Of infectious diseases 35 were notified during the year. Of these 10 were erysipelas, 1 enteric fever, 3 scarlet fever and 21 diphtheria. In 1890 there were 36 cases of diphtheria notified. Dr. Coleman says: "Correctly speaking, there has been no outbreak of diphtheria, for the succession of cases, spread over the whole year, are not to be so called and there is no reason for suspecting water, milk, or any article of food. Equally impossible is it to account for all of them by any theory of personal infection or of local or general sanitary defects." The steady persistence of diphtheria during two years in an otherwise healthy suburb and its great preponderance over the other infectious diseases is certainly a matter for inquiry. The medical officer of health is inclined to attribute it mainly to the large amount of damp prevailing during these two years.

## THE CHOLERA IN PARIS.

(FROM OUR SPECIAL CORRESPONDENT.)

A FORTNIGHT ago, under a pledge of absolute secrecy, I was informed that all the talk about cholera nostras and choleraic diarrhoea was concocted merely to avoid panic. It was necessary to account for the sudden deaths which were occurring in such a manner as to avoid alarming the public and none of the authorities dared to confess that cholera prevailed in and about Paris. Then I was told that careful bacteriological researches had been made. The comma bacillus had been found in the dejections of the patients. At first some doubts existed as to whether this was the real germ of Asiatic cholera. It was maintained that similar germs had been found in previous years and yet no cholera epidemic, as we generally understand the term, had occurred. Also it was found that, unlike the germ of Asiatic cholera, the comma bacillus had failed to give the usual reaction when grown in milk. Soon, however, it was seen that, if the bacillus was cultivated for three days, then its action upon milk was exactly similar to that produced by the germ of Asiatic cholera. Finally, these various experiments led to the conclusion that the comma bacillus, if not quite identical with that discovered and described by Dr. Koch in India, resembled in every respect the microbe of cholera cultivated at the Bacteriological Institute of Saigon by Dr. Calmette. As for the effects on the patients they were identical—rice-water evacuations, cramps, cold at the extremities, black vomit, cyanosis, &c. Post-mortem examinations have confirmed the opinions resulting from bacteriological researches; and by the side of what seemed to be cases of only cholera nostras, there have been other, and many other, cases that in no wise differed from Asiatic cholera.

Words are not strong enough to express the indignation that must naturally be felt at the persistent efforts made to conceal the true facts, which are now at last openly admitted and published in the medical world, though the daily political papers still continue to speak of the "choleraform" epidemic. The means of disinfection and isolation in and about Paris are far from perfect. The machinery at the disposal of the authorities to meet such emergencies is not very elaborate or complete; and this is especially the case in the outlying districts, the residents of which so far have been the principal sufferers. It was therefore necessary that everyone should be on the alert, that the intelligence and the devotion of the public should supplement what the authorities lacked

in means of action. Instead of this we have had a foolish attempt to hush up the matter, though previous experience should have shown how dangerous and futile such secrecy must be.

On Nov. 4th, 1884, Dr. Dujardin-Beaumez addressed the Academy of Medicine. He said now that the danger was all over, now that there had not been a case for an entire month, he would relate what measures had been taken and how a small epidemic of cholera having broken out in the suburbs of Paris the disease had been successfully stamped out. From June 24th to Oct. 4th the epidemic had prevailed, and though it had only caused forty deaths no doubt was entertained that these deaths were due to genuine cholera. Cholera was then existing at Marseilles and at Toulon, and it was easy enough to account for its probable importation to the neighbourhood of Paris. Dr. Dujardin-Beaumez congratulated himself and the Academy of Medicine on the fact that the epidemic was now quite over, that no alarm had been caused, and, in spite of the secrecy observed, efficient measures had been taken to prevent the epidemic spreading. On that very day (Nov. 4th), while Dr. Dujardin-Beaumez was thus confidently claiming that the danger was over, five cases of cholera occurred in Paris and two deaths ensued. A few days later (Nov. 10th) there were 110 deaths, and the epidemic continued to spread within the walls of Paris. Altogether 938 deaths occurred from cholera in Paris. This experience shows, first, that the cholera attacked the suburbs of Paris and remained in the suburbs for a considerable time before it came within the walls—that is, the fortifications—of Paris. It shows, further, that the secrecy then observed was of no avail in preventing the disease spreading, and finally that the subsidence of the cholera in the suburbs did not indicate that the danger was over.

With slight fluctuations the present epidemic is continuing and some cases have occurred within Paris. Perhaps an idea of the gravity of the situation may be formed from the fact that there were 217 disinfecting operations performed last year at the central stations in the course of the month of June, whereas during the month of June this year the number has increased to 1223. Since the month of May last no doubt can have been entertained that we were in face of genuine cases of cholera, and yet it is only within the last few days that the fact has been admitted. Some 200 deaths are supposed to have occurred, and the proportion of deaths is two out of every three cases. It would be reprehensible to wait for anything more serious than this before warning the public. In the suburbs of Paris the alarm is widespread in spite of the secrecy observed, and I have heard of some schoolmasters who accompanied the school-children back to their homes in order to see that they did not drink water on the road and recommended the parents to give them only boiled water. At St. Denis the cases have occurred principally among the inhabitants of the Quai de la Seine, the Boulevard Ornano, the Route de la Révolte and the Avenue de Paris, where the houses are all supplied with water from the Seine. The inhabitants of St. Denis who have escaped from the epidemic drink water taken from an artesian well. Somewhat late in the day, but still better late than never, the water companies have convoked a conference, which is to meet at Asnières, one of the suburbs near Paris, where there have been several cases of cholera. The conference is to discuss what are the best means of filtering water. There is no question as yet of supplying the suburbs of Paris with other than Seine water, but perhaps some better methods might be employed of filtering this water. But for the contamination of the Seine as it approaches and passes through Paris the water of the river would be good, and, as I have explained, in the suburbs of Paris the water is taken from the river after and not before it has reached the capital. Considering that two-thirds of the Paris sewage fall into the river it is not surprising if the water is contaminated.

Paris July 12th.

LYING-IN HOSPITAL, LIVERPOOL.—A new Cottage was formally opened on Tuesday, July 12th, which has been added to this institution on Brownlow-hill. The charity has existed nearly a century, having been established in 1796. In that year 126 patients were treated, at a cost of £450. Last year 2000 cases were dealt with, at an expenditure of £2150. The hospital on Brownlow-hill was erected some years ago, but additional accommodation had been found necessary, the total outlay for which (including furnishing) is £2000, and of this sum £900 is still required.

<sup>1</sup> The other instances quoted also press for an explanation.

HOSPITAL ACCOUNTS.

OUR readers are aware that the Council of the Hospital Sunday Fund, when circulating their request for the various hospital accounts a few months ago, suggested that these statements should in the present year be prepared in the form which had been drawn up by the Committee of Hospital Secretaries convened under the auspices of the Mansion House Council to consider that matter. The result of that suggestion is now before the public in the form of a series of financial statements for the present year and it must be confessed that it is a most disappointing result and one that augurs badly for the ultimate success of persuasive methods in improving the present modes of hospital administration. The result is disappointing because the authorities of the hospitals have paid so very little heed to the suggestion. In this it seems to us that they are equally ungracious and unwise—ungracious because the request was an eminently reasonable one, with which they might have complied at very little cost of trouble or inconvenience to themselves, and unwise because delay in a matter of this kind is much more likely to result in an aggravated demand than in any event more agreeable to the hospital authorities. The importance of uniformity in the presentation of accounts is a thing which has been clearly apprehended by the public or that section of the public which busies itself with such discussions, and it is not at all likely to pass out of sight. Even the Committee of the House of Lords, which has observed the strictest moderation in all its criticisms, has insisted on the importance of this reform, and has made further recommendations which proceed on the assumption that accounts will hereafter be rendered in some commonly adopted form. That being so, resistance to the movement which has for its object the security of this uniformity is now untimely, and those, if any such there are, who have reason to think that the form of statement which has been actually proposed would be ill adapted to their own use should, if well advised, be the first to attempt the task, and thus they may be able to convince either themselves or the Accounts Committee of their mistake. The statements now made public do not, however, show any sign of a serious or general effort to reduce this suggestion to the test of experience. Barely half a dozen institutions have adopted the suggested form; the rest have ignored it and reproduced the schedules which they have used heretofore, with the result that the new form, so far from bringing the statements into a uniform shape at the present time, has actually increased the existing confusion by superadding a new type to those already in use.

For this unfortunate result the Council of the Hospital Sunday Fund cannot be held in any way to blame. To them it is a matter of some consequence that the information upon which they have to apportion the funds committed to their charge should be supplied to them in a readily available form—that is to say, in a form which makes the comparison of various institutions as simple a matter as such a thing can be. At best it cannot be a really simple thing, so great is the diversity of the features which have to be compared, so many are the points at which general impressions and more or less vague estimates must of necessity take the place of exact analysis. It was therefore an eminently reasonable thing that the Council of the Fund should ask applicants to present their claims in a common form that would as far as possible facilitate comparison. Equally reasonable was the course which the Council adopted in the drafting and settling of the form. This was entrusted to a committee of hospital secretaries, who might fairly be expected to have the interest of their institutions not only at heart, but also very clearly in view; so that no demand for information would be likely to be put forward which could not be safely and easily satisfied. If the hospitals had been asked to furnish their accounts in the form, for example, which has been put forward in our pages and which was submitted by the representative of THE LANCET to the Lords' Committee, it might very possibly and very plausibly have been said that the change would involve a considerable departure from the familiar lines, and such an alteration in the method not only of presenting but also of keeping the accounts as could not well be accomplished offhand. No such objection can be alleged against the Hospital Sunday Fund Schedule. Its shortcoming is that it follows so closely the old and accustomed lines that it does not convey the information

which the public most desire and which it is necessary to bring clearly out in the interest of the hospitals themselves. In a word, the fundamental considerations of perspicuity and completeness in the statement have been sacrificed in the preparation of this form to the subordinate consideration of what will cost least trouble to the officer charged with the preparation of the accounts, and yet even to the extent of adopting a form of statement modified so slightly from that with which they are familiar the secretaries for the most part have refused to accede to the request of their benefactors.

The criticism which we have here passed upon the Council's form of financial statement merits a somewhat fuller reference than a mere passing allusion. The reason of our fault-finding has been, indeed, fully stated when we say that perspicuity and completeness are the qualities which, above all others, should be conspicuous in a document of this kind. But perspicuity and completeness are relative terms, which must be understood in relation to some purpose which the statement is to serve. Now, the end of a financial statement is to exhibit to the reader the financial condition of the account which it summarises. In the case of a hospital the financial condition is ascertained by considering (1) how much is annually expended on the work of the institution, (2) how that expenditure is distributed among the various departments; (3) what is the amount of the income available to meet the expenditure; and (4) from what sources that income is derived. These four heads of inquiry should be fully worked out. A statement which leaves any one of them in obscurity is to that extent incomplete. A statement which deals with them all may be passed as complete, and one which deals with them all in such a way as to be easily read and understood is both complete and perspicuous. Tried by this test the Council's form will be found to be wanting in both particulars. To allude, first, to its failure in respect of perspicuity. Those who drafted it have followed the prevalent but eminently perplexing practice of making the first entry on the income side of the account the amount of the balance brought forward from the previous year. This is a mere accountant's trick, and it has the mischievous result of making it impossible to discover without an arithmetical operation what is the actual income of the given year. An illustration will make this clear. Suppose that a given account contains the following items:

Balance brought forward from last account	£500	0	0
Income from charitable sources ... ..	10,000	0	0
Income from property ... ..	1000	0	0
Total... ..	£11,500	0	0

Here the total income of the year under notice does not at all appear, since the total figure represents not income only but income *plus* a balance which is the residue of the income of a previous year, the aggregate being an artificial sum which satisfies no other condition than that of balancing an equally artificial aggregate sum on the other side of the account. It would be quite easy to exhibit the self-same figures in a clearly intelligible form, thus—

Income from charitable sources ...	£10,000
Income from property ... ..	1000
Total income ... ..	£11,000
Balance brought forward from last account ... ..	500
Grand total ... ..	£11,500

Here the reader discovers at a glance what is the total amount of the income for the year, and if the expenditure be treated upon a similar plan he may discover at a glance whether the income of the year has balanced the expenditure or no. The form issued by the Council misses this point and, by introducing the balance brought forward at the head of the income column, involves the whole statement in needless obscurity.

Another point in respect of which this statement stands in need of improvement is the presentation of that part of the income which is derived from legacies. This is here shown under the head of "Extraordinary Income," a term which is doubtless intended to convey the meaning that the sums so classified are regarded as windfalls—sources of income not to be counted upon as yielding an annual return. To a large proportion of the income from legacies such a description is plainly applicable; but when it is found

that year after year for long periods of time legacies come in, sometimes in greater sometimes in smaller volume, but never sinking below a considerable figure, it is plain that no committee of reasonable men would think of actually regarding the whole of such income in this light. The proper course and the course always adopted in actual practice is to treat the income from legacies as falling under two heads. One part may fairly be regarded as "ordinary" or "regular" or "renewable" income not distinguishable in this respect from what is derived from annual subscriptions for example. The residue is properly classified as extraordinary or occasional income not to be counted upon, and when received, suitable rather for investment than to meet the ordinary outgoings of routine expenditure. Now this being by common consent the sound theory of hospital finance, the perspicuous way of stating the account must be to make a corresponding division in the statement and to carry part of the sum received from legacies to the ordinary and the residue to the extraordinary branch of income. The form now under discussion passes the whole in one sum to the head "extraordinary income."

These are small points, comparatively speaking, and in respect of them the form of statement adopted by the Council might be modified without adding in any way to the labour of preparing the account or the difficulty of persuading the hospitals to adopt it. With reference to the statement of expenditure, larger questions arise, and the views which we advocate would doubtless meet with more opposition, as involving a much more serious departure from existing practice. This, therefore, is a topic on which we cannot enter at the present moment—considerations of time and space forbid it. We reserve for another occasion this more debateable matter.

## DUBLIN UNIVERSITY TRICENTENARY.

### [SECOND NOTICE.]

On Thursday morning, the 7th inst., a procession of delegates, graduates, undergraduates and members of corporate bodies, in academic or official robes, passed through the streets from the Examination Hall, Trinity College, to the Leinster Hall. Previously to their arrival the string band of the Sussex Regiment performed a number of musical selections and during the presentation of addresses played the national airs of a good number of the countries represented. The hall where the presentation of addresses from the delegates to the University of Dublin took place was decorated with garlands of evergreens and flags, while the front of the galleries was festooned with draperies of gold and white cloth over a red ground; and plants and flowers were placed in different parts of the hall, which was exactly in the same condition as at the banquet given there on the previous evening. The arms of the College, in colours, were placed in various parts of the building; and it may be mentioned that the correct arms, as recent investigations have shown, are a castle with two towers, over which is a book—presumably the Bible—and above this a lion and a harp without the crown. The chair was taken by the Earl of Rosse, Chancellor of the University, and the Provost gave an address, being followed by the Lord Mayor. The Vice-Provost then called out the names of each member of the deputations presenting addresses, who passed up from the body of the hall and, shaking hands with the Chancellor and Provost, took their seats on the dais. Professor Richet, of the University of France, spoke in his native tongue and received quite an ovation from the large audience present, the other speakers being Sir James Paget, Bart., for the University of London; Mr. D. C. Gilman, LL.D., President of the Johns Hopkins University, U.S.; Professor Schipper, University of Vienna; Professor V. D'Hondt, University of Ghent; Professor H. M. Saxtorph, University of Copenhagen; Baron F. von Richthofen, University of Berlin; Professor C. P. Tiele, University of Leyden; Professor A. Vambóry, University of Buda-Pesth; Professor Gaudenzi, University of Bologna; Professor F. Hagerup, University of Christiania; Dr. T. T. Martens, University of St. Petersburg; Professor J. Kollmann, University of Basle; Dr. J. Peile, Vice-Chancellor, University of Cambridge; and Rev. H. Boyd, Vice-Chancellor of the University of Oxford. The following is the order in which the delegates were called upon by the Vice-Provost to present their addresses:—

*Africa*.—University of the Cape of Good Hope, Rev. J. Thompson.

*Australia*.—University of Adelaide, Professor J. Hudson Beare; University of Melbourne, Professor T. G. Tucker; University of Sydney, Hon. Peter Faucett and Mr. H. E. Barff.

*Canada*.—Queen's University, Kingston, Professor D. H. Marshall; McGill University, Montreal, Professor Alexander Johnson, Vice-Principal; University of New Brunswick, Professor W. F. Stockley; University of Toronto, Professor W. J. Ashley and Professor J. J. M. Baldwin; Trinity College, Toronto, Ven. Archdeacon Jones.

*India*.—University of Bombay, Sir Raymond West, K.C.I.E.; University of Calcutta, Sir A. Croft, K.C.I.E.; University of Madras, Mr. J. Kernan; University of Punjab, Hon. W. H. Rattigan, Vice-Chancellor.

*New Zealand*.—University of New Zealand, Professor H. L. Ferguson.

*England*.—University of Durham, Rev. Professor A. Plummer; King's College, London, Hon. R. C. Parsons; University College, London, Rev. Professor T. G. Bonney; Victoria University, Professor G. H. Rendall, Vice-Chancellor, and Professor A. S. Wilkins; University of London, Sir James Paget, Bart.

*Ireland*.—Catholic University, Very Rev. Monsignor Molloy, Rector; Queen's College, Belfast, Rev. T. Hamilton, President; Queen's College, Cork, Dr. J. W. Slattery, President; Queen's College, Galway, Dr. T. W. Moffett, President; Royal College of Physicians, Dr. J. Magee Finny, President, and Dr. J. W. Moore; Royal College of Surgeons, Dr. Edward Hamilton, President, and Sir Charles Cameron; Royal University, the Marquis of Dufferin and Ava, Chancellor.

*Scotland*.—University of Aberdeen, Sir W. D. Geddes, Principal, and Rev. James Myers Dawson; University of Edinburgh, Sir Wm. Muir, K.C.S.I., Principal, and Professor Masson; University of Glasgow, Professor Ramsay and Professor J. Ferguson; University of St. Andrews, Lord Acton.

*Wales*.—University College, Aberystwyth, Professor W. J. Johnston; University College, Bangor, Mr. H. R. Reichel, Principal; St. David's College, Lampeter, Professor A. W. Scott.

*America*.—Johns Hopkins University, Dr. D. C. Gilman, President, and Professor S. Newcomb; University of California, Professor W. Carey Jones; Columbia University, Professor H. T. Peck; Cornell University, Professor Hiram Corson; Harvard University, Professor W. G. Farlow; College of New Jersey, Rev. F. L. Patton, President; University of Pennsylvania, Dr. J. S. Billings, Professor E. J. James and Professor W. R. Newbold; Yale University, Professor T. R. Lounsbury and Rev. J. H. Twichell; National Academy of Sciences, Washington, General F. A. Walker; Smithsonian Institution, Dr. James C. Welling.

*Austria*.—University of Vienna, Professor J. Schipper; Academy of Sciences, Vienna, Professor Theodor Gmperz.

*Belgium*.—University of Ghent, Professor V. D'Hondt and Professor A. de Couleeneer.

*Denmark*.—University of Copenhagen, Professor H. M. Saxtorph.

*France*.—University of France, Professor Lannelongue, Professor Bonet-Maury, Professor Beljame, Professor Lafaye, Professor Richet, Professor Tisserand; Academy of Aix, Professor Joret; Academy of Caen, Professor Mabillean; Academy of Montpellier, Professor Soubeiran.

*Germany*.—University of Berlin, Baron F. von Richthofen; Royal Prussian Academy of Sciences, Berlin, Professor W. Waldeyer; University of Erlangen, Professor Paul Gordan; University of Göttingen, Professor Franz Kielhorn; University of Heidelberg, Professor A. Merx; University of Kiel, Professor Friedrich Blass; University of Munich, Professor Ludwig Boltzmann; University of Rostock, Professor Friedrich Hashagen; University of Strasburg, Professor G. F. Knapp.

*Holland*.—University of Leyden, Professor C. P. Tiele and Professor H. Oort, Rector; University of Amsterdam, Professor B. J. Stockvis, Rector Magnificus; University of Utrecht, Professor H. Snellen, Rector Magnificus.

*Hungary*.—University of Buda-Pesth, Professor A. Vambóry, Professor Z. Beothy.

*Italy*.—University of Bologna, Professor A. Gaudenzi; Accademia della Crusca, Florence, Sir J. Kingston James; Accademia dei Lincei, Rome, Professor F. Brioschi.

*Norway*.—University of Christiania, Professor F. Hagerup.

Russia.—University of St. Petersburg, Dr. T. T. Martens and Dr. N. E. Wedenski.  
 Switzerland.—University of Basle, Professor J. Kollman; University of Bern, Professor T. Studer, Rector; University of Geneva, Professor Nicole; University of Lausanne, Professor A. Maurer, Rector.  
 University of Cambridge.—Dr. J. Peile, Vice-Chancellor; Rev. H. M. Butler, Master of Trinity College; Professor A. Macalister, Sir G. G. Stokes, Bart.  
 University of Oxford.—Rev. H. Boyd, Vice-Chancellor; Sir H. Acland, Bart.; the Bishop of Oxford.

From 4 to 6 P.M. there was a garden party at the Royal Hospital, Kilmainham, given by General Lord Wolseley and Lady Wolseley, which was attended by a large number of guests; and at 8 P.M. the same evening there was a dramatic performance at the Gaiety Theatre. The theatre was crowded from pit to ceiling by guests and citizens, the National Anthem being sung on the arrival of His Excellency the Lord Lieutenant. The first play was a comic sketch written by Dr. Woods and C. W. Wilson, A.B., entitled "Botany Bay."

On Friday, the 8th inst., in the Examination Hall of Trinity College, addresses were delivered to the students by guests of the University. The chief speakers were: Professor Wilhelm Waldeyer of Berlin; Professor Cremona of Rome, who spoke in Italian; Professor Max Müller, who delivered an eloquent and interesting address; M. Leon Say; General Walker of Boston; and Professor G. Bonet-Maury of Paris. Later in the evening the Lord Chancellor gave a banquet to 150 guests in the dining-hall of the King's Inns. The toast of "The Universities of the World" was given by Professor Dowden in felicitous language and was replied to by Professor Cremona, Dr. Martens (St. Petersburg) and Baron von Richthofen. The University ball in the Leinster Hall the same evening was a brilliant and successful affair and fitly terminated the week's proceedings. Earlier in the day Lord and Lady Rosse entertained at Birr Castle a large number of Tercentenary visitors, luncheon and afternoon tea being provided. Great interest was shown in Lord Rosse's famous telescope, which was exhibited and minutely explained by the astronomer, Dr. Boedicker. The visitors, who thoroughly enjoyed their day's outing, were conveyed in his lordship's vehicles to and from the railway station, special trains being engaged both going and returning. The weather during the week, it may be added, was exceptionally good.

METROPOLITAN HOSPITAL SUNDAY FUND.

The following list is a continuation of the contributions received at the Mansion House up to Thursday last in aid of the Metropolitan Hospital Sunday Fund. The amount received up to the present is £37,100; the amount at the corresponding date in 1891 was £39,250.

	£	s.	d.
St. Barnabas, Pimlico (Rev. Alfred Gurney) .. .. .	20	10	0
Box outside Mansion House .. .. .	5	6	3
St. Mary and St. John the Divine, Balham (Rev. Thos. Bates) .. .. .	55	8	11
St. James', Hatcham (Rev. W. H. Stone) .. .. .	41	12	0
All Saints, Putney (Hon. and Rev. R. Henley) .. .. .	32	0	0
Islington Parish Church (Rev. W. H. Barlow) .. .. .	20	11	0
St. Stephen with St. Thomas Iron Church, Paddington (Rev. T. Harvey Brooks) .. .. .	100	11	11
St. Peter, Bayswater (Rev. C. N. Moore) .. .. .	100	11	8
Christ Church and St. Barnabas, North Finchley (Rev. H. Stephens) .. .. .	28	10	11
Blackheath Congregational Church (Rev. Chas. Wilson, M.A.) .. .. .	100	10	6
St. Stephen, Gloucester-road (Rev. J. P. Waldo) .. .. .	218	13	6
St. John the Divine, Kennington (Rev. C. E. Brooke) .. .. .	60	11	1
St. John's, Notting-hill (Prebendary R. Thornton) .. .. .	74	12	2
St. Agnes, Kennington Park (Rev. T. B. Dover) .. .. .	25	3	1
Wilmington Parish Church (Rev. E. Jamblin) .. .. .	22	2	6
J. J. Randolph, Esq. .. .. .	20	0	0
Harecourt Chapel, Canonbury (Rev. H. Simon) .. .. .	20	0	0

"MEDICAL AID SOCIETIES AND THE PROFESSION."

In an annotation bearing the above heading on page 98 of our last issue, we stated that we should be happy to obtain a legal opinion on the points raised by our correspondents if one of the bonds in question were furnished to us. A form of agreement has been submitted on which we have, through our solicitors, obtained a legal opinion from Mr. J. W. Gordon, Barrister-at-Law, which we subjoin.

Opinion.

The agreement as to which I am asked to advise the Editors of THE LANCET is made between a medical practitioner of the one part and the trustees of an unregistered medical aid society of the other part and binds the former to serve the society in a professional capacity, giving his whole time thereto in return for a salary of one hundred and fifty pounds a year in addition to a residence and an allowance equal to three-fourths of the amount earned by him in the way of midwifery and vaccination fees. It is a special term of this agreement that the medical officer "agrees that he will not, either directly or indirectly, undertake private practice while in the service of the said Association, and on his engagement with the said Association being determined he will not, either directly or indirectly, practise as a physician or surgeon within a radius of seven miles of the surgery within a period of five (years<sup>1</sup>) from the time of his engagement as aforesaid being determined, under a penalty of two hundred pounds as liquidated ascertained damages."

These terms appear to be very onerous, but I entertain no doubt that the agreement is binding and could be enforced by the trustees. Two remedies would be open to them if the medical man were to commence practice in violation of the agreement—that is to say, an injunction to restrain the breach or a judgment for the amount of the penalty. If the latter remedy were followed they could recover the full amount—£200—of the agreed damages.

I will deal in order with the points about which I understand doubt to have arisen.

1. Although the society is unregistered, the agreement, being made with trustees, could be by them enforced.

2. There is consideration sufficient to support the agreement in the fact that the medical officer received his appointment upon these terms. This has long been settled law and was so laid down by the late Master of the Rolls (Jessel) in the case of Gravelly v. Barnard (18 L. R. Eq. 518).

3. The limits imposed are not unreasonable in respect either of space or time. So long ago as the end of the last century it was decided that a radius of ten miles and a period of fourteen years were for this purpose reasonable

<sup>1</sup> The word "years" is omitted from the copy agreement supplied to me.—J. W. G.

limits. (*Davis v. Mason*, 5 T.R., 120.) More recent decisions make it clear that no time limit need be imposed if the undertaking be reasonably limited in respect of the prohibited area.

4. The language of the clause in question is very involved and indeed ungrammatical; so much so that upon first reading I was disposed to doubt whether the meaning had been made sufficiently clear for a Court to act upon it. But upon fuller consideration I am satisfied that the intention of the parties is made clear enough. In coming to this conclusion I have borne in mind the very vague terms of a similar agreement to which effect was given in the case of *Saunter v. Ferguson* (7 C.B. 716).

J. W. GORDON.

Plowden-buildings, Temple, July 14th, 1892.

## Public Health and Poor Law.

### LOCAL GOVERNMENT DEPARTMENT.

#### REPORTS OF MEDICAL OFFICERS OF HEALTH.

*Withington Urban District.*—The annual death-rate in this local board district last year was 15·0 per 1000, a rate in excess of that which has for some years past prevailed. The zymotic rate was as low as 0·6, and no death occurred from any of the continued fevers or from small-pox. When attacks of infectious disease occurred they were promptly attended to; some cases were removed to Monsall Hospital, and local sanitary defects were dealt with. Measures are being adopted as to the disposal of refuse, but the necessary preliminaries do not appear to be settled. The ash-pit privy still retains its hold on the district, 2947 such structures being in existence; and, contrary to common experience, the scavenging is said to be perfectly satisfactory. Appended to Dr. Railton's report is a good account of the work done by the sanitary inspector.

*Epping Rural Sanitary District.*—Following upon an account of the attacks from infectious diseases, which included twenty-three of scarlet fever and fifteen of diphtheria in Chigwell alone, comes a somewhat detailed statement as to the sanitary inspections carried out during the year. The value of real isolation seems to have but little hold on the public mind, for only two cases were removed to the sanatorium. The main sanitary requirements of the district are set out by Mr. Trevor Fowler as follows:—Better houses for the working classes; better drainage for villages, hamlets and groups of houses; abolition of cesspools and connexion of houses with existing sewers; the supply of proper water in place of that derived from surface wells; the securing of certain urban powers; and the proper fitting of the sanatorium. The death-rate for the year was 16·9 per 1000.

*Whitechapel.*—Mr. Loane's district now includes a population of 74,261, and the death-rate during 1891 was 24·7 per 1000. Whilst the general death-rate is greater than that for the metropolis, the zymotic rate contrasts favourably with that for London as a whole. This must be regarded as satisfactory in view of the difficulties which Whitechapel presents. Of this class of diseases the largest number of deaths was thirty from diphtheria, a disease which is making substantial inroads on large communities. Improved dwelling accommodation is continuing to be made and 337 fresh apartments have been provided in model dwellings during the year; houses unfit for habitation have been closed, pulled down or repaired, and this on an extensive scale. Mr. Loane also gives an excellent summary of the London Public Health Act such as must be of considerable value to many residents and others who are not in touch with Acts of Parliament. Great improvements are anticipated as work progresses on the new lines indicated, and we hope Mr. Loane is right in saying that the "house sweaters" will find the Act in this respect a "terror" to them. The sanitary staff will need increasing for the steady increase in duty that is in prospect, and to this aspect of affairs attention is very properly drawn at the onset.

### VITAL STATISTICS.

#### HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6362 births and 3347 deaths were registered during the week ending July 9th. The annual rate of mortality in these towns, which had declined in the preceding three weeks from 17·8 to 17·1 per 1000, was again 17·1 last week. In London the rate was 17·2 per 1000, while it averaged 17·1 in the thirty-two provincial towns. The lowest rates in these towns were 10·2 in Norwich, 10·3 in Croydon, 11·1 in Cardiff, and 13·0 in Brighton; the highest rates were 20·6 in Wolverhampton, 20·1 in Manchester, 22·1 in Liverpool, and 23·2 in Sunderland. The 3347 deaths included 503 which were referred to the principal zymotic diseases, against 477 and 486 in the preceding two weeks; of these, 161 resulted from diarrhoea, 134 from measles, 83 from whooping-cough, 49 from scarlet fever, 47 from diphtheria, 28 from "fever" (principally enteric), and 1 from small-pox. The lowest death-rates from these diseases were recorded in Brighton, Norwich, Huddersfield and Bolton; the highest in Preston, London, Leicester, and West Ham. The greatest mortality from measles occurred in London, West Ham, Birmingham, Nottingham, Leicester, Gateshead, and Halifax; from scarlet fever in West Ham, Preston, Swansea, and Plymouth; from whooping-cough in Manchester, Burnley, and Blackburn; from "fever" in Preston and in Hull; and from diarrhoea in Liverpool, London, and Leicester. The 47 deaths from diphtheria included 30 in London, 4 in Birmingham, 2 in West Ham, 2 in Nottingham, and 2 in Newcastle-upon-Tyne. A fatal case of small-pox was registered in London, but not one in any of the thirty-two provincial towns; 27 cases of this disease were under treatment in the Metropolitan Asylum Hospitals and 5 in the Highgate Small-pox Hospital on Saturday last. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2372, against numbers increasing from 1226 to 2211 on the preceding fifteen Saturdays; 301 new cases were admitted during the week, against 284 and 331 in the previous two weeks. The deaths referred to diseases of the respiratory organs in London, which had been 181 and 185 in the preceding two weeks, declined to 170 last week, and were 29 below the corrected average. The causes of 59, or 1·8 per cent., of the deaths in the thirty-three towns were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Bristol, Nottingham, Bradford, Leeds, and in twelve other smaller towns; the largest proportions of uncertified deaths were registered in Cardiff, Birmingham, Liverpool, Preston, and Hull.

#### HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·3 and 18·0 in the preceding two weeks, further declined to 17·6 during the week ending July 9th, but was 0·5 per 1000 above the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 12·0 in Perth and 12·6 in Leith to 19·1 in Paisley and 20·6 in Glasgow. The 489 deaths in these towns included 22 which were referred to measles, 21 to whooping-cough, 7 to diarrhoea, 5 to scarlet fever, 4 to "fever," 3 to diphtheria, and not one to small-pox. In all, 62 deaths resulted from these principal zymotic diseases, against 85 and 83 in the preceding two weeks. These 62 deaths were equal to an annual rate of 2·2 per 1000, which was 0·4 below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had been 35 and 31 in the preceding two weeks, further declined last week to 22, of which 20 occurred in Glasgow. The deaths referred to whooping-cough, which had been 27 and 23 in the previous two weeks, further fell to 21 last week, and included 19 in Glasgow. The 7 fatal cases of diarrhoea also showed a slight further decline from those recorded in recent weeks. The deaths from scarlet fever, which had been 3 and 9 in the preceding two weeks, fell to 5 last week, of which 3 occurred in Glasgow and 2 in Edinburgh. The 3 fatal cases of diphtheria showed a decline of 4 from the number in the previous week.

and included 2 in Glasgow and 1 in Paisley. The deaths referred to diseases of the respiratory organs in these towns, which had been 80 and 89 in the preceding two weeks, declined last week to 71, and were 6 below the number in the corresponding week of last year. The causes of 52, or nearly 11 per cent., of the deaths in these eight towns last week were not certified.

#### HEALTH OF DUBLIN.

The death-rate in Dublin, which had declined from 31.6 to 24.6 per 1000 in the preceding three weeks, further fell to 21.8 during the week ending July 9th. During the thirteen weeks of last quarter the death-rate in the city averaged 31.3 per 1000, against 18.9 in London and 17.8 in Edinburgh. The 146 deaths in Dublin during the week under notice showed a decline of 19 from the number in the preceding week and included 13 which were referred to measles, 3 to diarrhoea, 2 to whooping-cough, 1 to diphtheria, 1 to "fever," and not one either to small-pox or scarlet fever. In all, 20 deaths resulted from these principal zymotic diseases, equal to an annual rate of 3.0 per 1000, the zymotic death-rate during the same period being 3.4 in London and 0.8 in Edinburgh. The fatal cases of measles, which had declined from 27 to 20 in the preceding three weeks, further fell to 13 last week, a lower number than in any week since March last. The 3 deaths from diarrhoea exceeded the number in any recent week. The fatal cases of whooping-cough, which had been 5 and 1 in the previous two weeks, were 2 last week. The death referred to diphtheria was the first recorded within the city since the beginning of May last. The 146 deaths registered in Dublin last week included 27 of infants under one year of age and 31 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons slightly exceeded the numbers recorded in the preceding week. Eight inquest cases and 5 deaths from violence were registered; and 35, or nearly a fourth, of the deaths occurred in public institutions. The causes of 10, or nearly 7 per cent., of the deaths in the city last week were not certified.

#### VITAL STATISTICS OF LONDON DURING JUNE, 1892.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality during the month of June in each of the forty-one sanitary districts of London. With regard to the notified cases of infectious disease in London during last month, it appears that the number of persons reported to be suffering from one or other of the ten diseases specified in the accompanying table was equal to 9.9 per 1000 of the population, estimated at 4,263,294 persons in the middle of this year. Owing to the epidemic prevalence of scarlet fever in the metropolis this rate shows a further increase upon those recorded in the preceding four months, which had risen from 5.1 to 9.4 per 1000. Among the various sanitary districts the rates last month were considerably below the average in Paddington, Fulham, Hampstead, Strand, St. Saviour (Southwark), St. Olave (Southwark), and Rotherhithe; while they showed the largest excess in Westminster, Holborn, City of London, Bethnal-green, Whitechapel, Mile End Old Town, Poplar, Newington, Woolwich, and Plumstead. The prevalence of small-pox showed a marked decline in London, an average of 16 cases weekly being notified in June, against 27 in May; of the 80 cases notified during last month 16 belonged to Shoreditch, 8 to Whitechapel, 7 to Islington, 7 to Lambeth, and 7 to Plumstead sanitary districts. The Metropolitan Asylum Hospitals and the Highgate Small-pox Hospital contained 40 small-pox patients at the end of June, against 108 at the end of May; the weekly admissions averaged 11, against 29 during the preceding month. The prevalence of scarlet fever during June showed a further marked increase upon that recorded in recent months. This disease was proportionally most prevalent in Hackney, Holborn, City of London, Whitechapel, Mile End Old Town, Poplar, Newington, Woolwich, and Plumstead. The Metropolitan Asylum Hospitals contained 2117 scarlet fever patients at the end of June, against numbers increasing from 1142 to 1652 at the end of the preceding four months; the weekly admissions averaged 238, against 118, 170, and 200 in the previous three months. Diphtheria showed the highest proportional prevalence during June in Hammersmith, Westminster, Hampstead, City of London, Bethnal Green, Whitechapel, and Mile End Old Town. There were 255 cases of diphtheria under treatment

in the Metropolitan Asylum Hospitals at the end of June, against numbers increasing from 198 to 220 at the end of the preceding four months; the weekly admissions averaged 49, against 28, 33, and 41 in the previous three months. Among the various sanitary districts enteric fever was proportionally most prevalent in St. Martin-in-the-Fields, Bethnal Green, and Rotherhithe. The Metropolitan Asylum Hospitals contained 57 enteric fever patients at the end of June, against numbers steadily declining from 285 to 47 at the end of the preceding seven months; the weekly admissions averaged 10, against 9 and 8 in the preceding two months. Erysipelas showed the highest proportional prevalence during June in Marylebone, Bethnal Green, Whitechapel, Limehouse, and Greenwich.

The mortality statistics in the accompanying table relate to the deaths of persons actually belonging to the various metropolitan sanitary districts, the deaths occurring in the institutions of London having been distributed among the various sanitary districts in which the patients had previously resided. The distribution of these deaths, and especially of those resulting from zymotic diseases, affords the most trustworthy data that can be secured upon which to calculate reliable rates of mortality. During the five weeks ending July 2nd the deaths of 6910 persons belonging to London were registered, equal to an annual rate of 16.9 per 1000, against rates declining from 24.2 to 18.8 in the preceding four months. The lowest death-rates in the various sanitary districts during June were 10.0 in Hampstead, 11.3 in Lewisham (excluding Penge), 11.4 in Wandsworth, 12.0 in Plumstead, 13.8 in Battersea, 14.3 in Hackney, and 14.4 in Islington; in the other sanitary districts the rates ranged upwards to 21.6 in Limehouse, 21.9 in the Strand, 22.2 in Mile End Old Town, 22.4 in Newington, 23.4 in Holborn, 23.7 in Whitechapel, and 29.9 in St. George-in-the-East. During the five weeks of June 1249 deaths were referred to the principal zymotic diseases in London; of these, 556 resulted from measles, 200 from diarrhoea, 187 from diphtheria, 159 from whooping-cough, 110 from scarlet fever, 31 from "fever" (including 28 from enteric and 3 from simple fever) and 6 from small-pox. These 1249 deaths were equal to an annual rate of 3.1 per 1000, against rates steadily increasing from 2.5 to 3.3 in the preceding four months. Among the various sanitary districts the lowest zymotic death-rates were recorded in St. Martin-in-the-Fields, Strand, St. Olave (Southwark), Lewisham, Woolwich and Plumstead; and the highest rates in Hammersmith, Whitechapel, St. George-in-the-East, Mile End Old Town, St. George (Southwark) and Newington. Six fatal cases of small-pox belonging to London were registered during June, of which 2 belonged to St. Luke, and one each to Chelsea, Camberwell, Greenwich, and Plumstead. The 556 deaths referred to measles exceeded by as many as 235 the corrected average number in the corresponding month of the preceding ten years; among the various sanitary districts this disease showed the highest proportional fatality in Paddington, Kensington, Hammersmith, Whitechapel, Mile End Old Town, and Newington. The 110 fatal cases of scarlet fever were 22 above the corrected average number; this disease was proportionately most fatal in Westminster and Newington. The 187 deaths referred to diphtheria were nearly double the corrected average; this disease showed the highest proportional fatality in Hammersmith, City of London, Whitechapel, St. George-in-the-East, and Mile End Old Town. The 159 fatal cases of whooping-cough were 118 below the average; among the various sanitary districts this disease was proportionally most fatal in Limehouse, St. George (Southwark) and Newington. The 28 deaths referred to enteric fever were 17 below the corrected average; this disease showed no marked excess last month in any of the sanitary districts. The 200 fatal cases of diarrhoea were 55 above the average; this disease was most fatally prevalent in Shoreditch, Whitechapel, and Mile-end Old Town. In conclusion, it may be stated that the mortality in London during June from these principal zymotic diseases in the aggregate was as much as 22 per cent. above the average, owing principally to the epidemic prevalence of measles.

Infant mortality in London, measured by the proportion of deaths under one year of age to registered births, was equal to 125 per 1000 during June; the lowest rates of infant mortality were recorded in St. James (Westminster), St. Martin-in-the-Fields, St. Olave (Southwark), Rotherhithe, Wandsworth, Woolwich, and Plumstead; the highest rates in Holborn, Clerkenwell, Shoreditch, Whitechapel, and St. George-in-the-East.

MONTHLY ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON.—JUNE, 1892.  
(Specially compiled for THE LANCET.)

Sanitary areas.	Estimated population in the middle of 1892.	NOTIFIED CASES OF INFECTIOUS DISEASE.										DEATHS FROM PRINCIPAL INFECTIOUS DISEASES.																
		Small-pox.	Scarlet fever.	Diphtheria.	Typhus fever.	Enteric fever.	Other continued fevers.	Puerperal fever.	Rhysselas.	Croup.	Cholera.	Total.	Annual rate per 1000 persons living.	Small-pox.	Measles.	Scarlet fever.	Diphtheria.	Whooping-cough.	Typhus fever.	Enteric fever.	Other continued fevers.	Diarrhoea.	Total.	Annual rate per 1000 persons living.	Deaths from all causes.	Death-rate per 1000 living.	Deaths of infants under one year to 1000 births.

## THE SERVICES.

## THE PROFESSORSHIPS AT NETLEY.

THE question of the professorships at Netley gravely affects the interests of both the Army Medical Service and Army Medical School. Surgeon-Colonel Godwin, it will be remembered, was appointed to the Chair of Military Surgery at Netley in succession to Sir Thomas Longmore, C.B. It has been decided that Surgeon-Colonel Godwin is not to draw the pay and allowances of his rank, but those of the professorship he holds; and as there is a considerable difference between the two, Surgeon-Colonel Godwin not unnaturally objects to be subjected to a serious pecuniary loss for the honour of being Professor of Military Surgery at Netley. Owing to the death of Sir William Aitken, the appointment of Professor of Pathology is also vacant. No officer of the Medical Staff has probably the same claims to the appointment, on the score of ability, special knowledge and previous training as assistant professor of the subject, as Surgeon-Colonel F. H. Welch; but the decision in the case of Surgeon-Colonel Godwin is applicable to both cases alike and governs the decision of the officers in question. Surgeon-Colonel Godwin resigns his professorship and Surgeon-Colonel Welch declines to accept that of pathology without the emoluments of his present rank. It is understood that the former officer reverts to the service and goes to India, and the latter will probably proceed to the Devonport district as principal medical officer. This will deprive the list of brigade surgeons of two steps of promotion. It seems probable that a civilian will have to be selected for the chair of Pathology in succession to Sir William Aitken; but we may assume that his chair of Military Surgery cannot be filled by anyone but a military medical officer with the requisite rank, reputation, experience and qualifications for such an appointment. It is a very laudable ambition for a medical officer to desire to fill a professorial chair at the Netley school and it seems to be distinctly in the interest of the public service that such appointments should be regarded as prizes for medical officers. It must surely be a wise policy to encourage medical officers to maintain and develop a high standard of professional knowledge and efficiency and to strive to qualify themselves for appointments in their own special institutions.

## THE ROYAL UNITED SERVICE INSTITUTION.

A good deal of interest has been displayed of late in regard to the financial position and prospects of the Royal United Service Institution. The institution has done good work in the past. We can recall some excellent lectures delivered within its walls by the late Professors Parkes and De Chaumont, and in these days, when army hygiene and the application of modern medicine to modern war are matters of great interest, there must be a number of subjects on which medical officers are well qualified to speak. An institution of the kind should bring together representatives of all branches of the service and be instrumental in disseminating much useful information on various subjects which dovetail into one another in naval and military services. The powers of the institution in this direction might possibly be further developed. Courses of lectures of a thoroughly practical kind might be given by experts on a variety of subjects not only to officers, but to non-commissioned officers and men of the Army, Militia and Volunteer forces. It has been urged that the medical services should support the institution by joining it in larger numbers than they at present do.

## MOVEMENTS OF THE MEDICAL STAFF.

Surgeon-Captain Sawyer has been granted leave from Gibraltar. Surgeon-Captain H. Adamson has re-embarked for Bombay. Surgeon-Captain C. G. Woods has rejoined at Portsmouth, from sick leave. Surgeon-Captain Bostock has resumed his duties in London, on return from Pirbright. Surgeon-Lieutenant-Colonel Finlay has left Aldershot on leave. Surgeon-Lieutenant-Colonel Beamish has been appointed to the Royal Arsenal, Woolwich, in succession to Surgeon-Major Murphy, deceased. Surgeon-Lieutenants Mitchell, Hennessy and Tyacke have reported themselves at Chatham for duty in the Thames district. Surgeon-Captain Burke has rejoined at Colchester, from leave. Surgeon-Lieutenant Dunn has joined at Woolwich for duty. Surgeon-Colonel Jameson has arrived from Egypt, on sick leave. Surgeon-Captain Reckitt has left Shorncliffe on leave. Surgeon-Captain Freyer has rejoined at Belfast. Brigade-

Surgeon-Lieutenant-Colonel O'Brien has left Dublin, on leave of absence. Surgeon-Captain Baylor has proceeded to Kilkenny for duty.

By the death of Surgeon-General Hassard, retired pay, a good-service pension becomes available for disposal. As Surgeon-General Hassard obtained this pension whilst on the effective list the recipient of the vacant distinction will presumably be a full-pay officer.

## INDIAN MEDICAL SERVICE.

Surgeon-Captain H. A. de Lom, M.S., is attached to the Station Hospital, Colaba, for duty. — Surgeon-Captain H. W. G. Macleod, M.B., 19th (Punjab) Regiment of Bengal Infantry, has been permitted to resign the service from April 25th, 1892, subject to Her Majesty's approval. — Surgeon-Captain T. Grainger is appointed to officiate as Civil Surgeon at Champaran during the absence, on deputation, of Surgeon-Major E. Bovill. — Surgeon-Captain J. G. Jordan is appointed to act as Civil Surgeon of Jessore. — Surgeon-Captain W. H. M. Ingham, on expiration of sick leave, is ordered to do duty in Rangoon district. — On return from deputation duty with the Government of India, Military Department, Surgeon-Captain W. G. Thorold is appointed to the civil medical duties of the Kheri district.

NAVAL MEDICAL SERVICE.—The appointment of Principal Medical Officer at Melville Naval Hospital, Chatham, rendered vacant by the transference of Deputy-Inspector-General T. S. Burnett to Jamaica, has been conferred by the Admiralty on Deputy-Inspector-General Belgrave Ninnis, M.D. — Staff Surgeon A. L. Christie, M.B., has been appointed to the *Naiad*; Fleet Surgeon T. M. Clement, M.D., to the *Clyde*; Surgeon J. O. B. Williams, M.B., to the *Iron Duke*; and Surgeon J. J. Walsh to the *Bramble*.

MILITIA MEDICAL STAFF CORPS.—Hants Company: Surgeon-Captain Walter Scott Warlters from Norwich Company Volunteer Medical Staff Corps to be Surgeon-Captain (dated June 29th, 1892).

VOLUNTEER CORPS.—*Artillery*: 1st Devonshire (Western Division, Royal Artillery): Charles Frederick Rudd, Gent., to be Surgeon-Lieutenant (dated July 9th, 1892). — 2nd East Riding of Yorkshire (Western Division, Royal Artillery): Surgeon-Lieutenant Albert Wilson to be Second Lieutenant (dated July 9th, 1892).

"Audi alteram partem."

## "ASPIRATION IN PNEUMOTHORAX."

To the Editors of THE LANCET.

SIRS,—Will you kindly allow me a few lines in reply to the letters in THE LANCET of July 2nd by Professor Gairdner and Dr. Guthrie on the above subject. Dr. Gairdner asks how it was ascertained that no air passed out of the pleural cavity on simple puncture. This conclusion was arrived at from the facts that no rush of air was to be felt, that no movement was communicated to a piece of wool held over the end of the hollow needle and that no change in the position of the displaced heart could be made out. Dr. Gairdner further infers that if air passed out of the pleural cavity by means of aspiration "it would also pass out without the aspirator to such an extent as was needful to relieve pressure." What pressure is meant? The fact that no air escaped after simple puncture indicated clearly that the intra-pleural pressure was not greater than that of the atmosphere, and that therefore relief could come only by slow re-expansion of the retracted lungs, which would allow of the heart swinging back towards its normal situation and thus free the embarrassed circulation. Dr. Gairdner says that in time this would have taken place, but he seems to forget that the patient was so collapsed that full inspiratory movements were not to be expected, and that syncope from cardiac displacement was imminent. In Dr. Gairdner's very successful case, to which he refers, the conditions were entirely different, for there was a rush of air out of the pleural cavity immediately on puncturing with, presumably, instant relief to the urgent symptoms. On the other hand, what was the object in aspirating? Dr. Gairdner erroneously assumes that it was "remove to the whole or the greater part of the air." I hoped by

aspiration to produce such an exhaustion of air in the pleural cavity as would allow of the re-expansion of the *sound* lung, with return of the mediastinum and heart towards their normal position, and as soon as this was affected the needle was withdrawn. This hope was based on the now generally accepted teaching of Dr. Douglas Powell that "the primary cause of displacement of the heart in pneumothorax is not air pressure acting from the diseased side, but lung traction acting upon the healthy side"<sup>1</sup>. Dr. Gairdner seems to imagine that my routine treatment of pneumothorax is by aspiration, but I tried to show in my paper that it was adopted as a last resort to relieve cardiac asthenia, after rest, stimulants, time and finally puncture had failed.

Having tried to reply to the criticisms of Dr. Gairdner on my employment of aspiration in this case I must now consider Dr. Guthrie's advocacy of more frequent aspiration than I ventured to employ, owing to my belief that compression and rest of the lung are beneficial in phthisis. In discussing the pathology Dr. Guthrie confines his attention to the retracted, healthy portion of the lung, which he believes to be adapted for the inroad of the tubercular virus, but ignores the altered condition of the portion of lung which is already phthisical. Before the onset of pneumothorax a consolidated area, except at the extreme apex, is prevented from natural healing by contraction, owing to the rigid chest wall and the traction by the sound part of the lung during inspiration. If rest be secured to the lung by pneumothorax, and if the rigid wall be replaced by an elastic body such as air, nature may then get her opportunity and complete the cure by contraction and cicatrization. Dr. Guthrie further considers pneumothorax a pure accident, and by no means an indication of active phthisis. While this may be true exceptionally, as in the case of a ruptured emphysematous area, it is not generally so. Professor Gairdner has shown<sup>2</sup> that the progress of tubercular disease in the lungs is accompanied by a plastic inflammation of the neighbouring pleura and that the resulting pleuritic adhesions are often in advance of the actual deposit of tubercle near the surface. Were it not for this "curious and beautifully conservative arrangement" pneumothorax would be the rule and not the exception in phthisis, and its occurrence is usually to be explained by the rapid advance of the disease before pleuritic adhesions have had time to form.

I am, Sirs, yours obediently,

Carlton-hill, N.W., July 11th, 1892. G. A. SUTHERLAND.

### "TOOTH CULTURE."

To the Editors of THE LANCET.

SIRS,—Innate imperfections in the tissues, especially in enamel, form the prime factor in the etiology of dental caries, and there exists enough evidence to prove that these imperfections are in the main due to evolutionary and hereditary influences. In all civilised races the size and strength of the whole apparatus of mastication—jaws, muscles and teeth—are inferior. Professor Flower showed some years ago, after examination and measurement of many thousands of specimens, that there is gradual diminution in the size of the teeth from the anthropoid apes through the lower races of man to the European. He constructed a "dental index" and in this the average size of the teeth of the gorilla was represented by 50.8, the Tasmanian by 47.5; other savage and primitive races held intermediate positions, and the European stood at 40.5. Striking evidence of the influence of heredity is afforded daily in dental practice. Nothing is more common than to find in members of the same family jaws and teeth of one general type of quality. Very often the characters are derived from one parent alone—boys "taking after" the mother, girls after the father—and not only does it seem certain that a type of jaw is transmissible but also that a small local deformity or a mal-development of a portion of the maxilla may be passed on to succeeding generations. A tooth or two in the set will also often be found irregularly placed in a parent and some of the progeny; in other instances teeth are to be found presenting in exactly the same situations in parent and child flaws or patches of inferior enamel. It is not uncommon to meet with a mother having first-rate dental tissues who brings forth children whose teeth are inferior and bear the closest resemblance in form and structure to those of the father, and he may be

perfectly healthy and free from any physical defect except the dental.

There can be no doubt that enamel and dentine when once fully calcified are not the seat of physiological activity and do not undergo processes of waste and repair. It must be therefore futile to attempt by therapeutic means the prevention of caries by improving the quality of enamel after formation of that tissue. The exteriors of the crowns of all the temporary teeth—from caries of which children suffer so much—are formed at birth; and these teeth can therefore be influenced only through the mother. By the same time the permanent first molars, incisors and canines are so far advanced in development that it is open to doubt whether later treatment can have any effect upon their enamel. That hereditary disease is capable of influencing the development of enamel and dentine has been proved by the observations of Mr. Hutchinson, and, although the typical teeth which he has described are discoverable in only a small percentage of children, unquestionably syphilitic, their occurrence clearly shows that ill-made teeth may result from a constitutional taint. A considerable variety of malformed teeth with pitted rocky ridged or spinous surfaces, commonly classed as "honeycombed" teeth, are frequently met with and are often mistaken for syphilitic teeth. The defects of these teeth are due to causes acting upon the enamel during calcification; probably some form of stomatitis implicating the tooth-sacs in earliest infancy. Mr. Hutchinson has adduced much evidence to prove that the stomatitis in many instances is caused by administration of mercury immediately after birth. It seems sufficiently obvious that if "tooth culture" is to be practised on a rational basis measures must be in the main directed to the improvement of the race. Strict observance of the laws of health will tend to produce good teeth in the nation, and among these laws must be included one insisting upon the use of articles of diet which shall give due exercise to the muscles of mastication and prevent them and the bones to which they are attached from wasting. Such exercise begun early enough may do good in the individual by stimulating the development of the maxillæ and preventing crowding and irregularity of the teeth—a fruitful cause of decay. Crowding leads to lodgment of debris which fermenting produces acid, the indispensable agent in dental caries. It is not likely that dental surgeons will agree with Dr. Harry Campbell, who in THE LANCET of to-day recommends that children should be encouraged to crack nuts with their teeth in order to exercise their jaws, but there is no difficulty in arranging a child's dietary during the whole period of dentition so that articles of food—such as stale crusts and hard biscuits—may be introduced which shall give the masticating apparatus enough work to ensure a more vigorous development than is likely to follow the exclusive use of soft bland substances which require no chewing whatever.

I am, Sirs, yours faithfully,

Wimpole-street. July 9th, 1892.

HENRY SEWILL.

### "ON ACTINOMYCOSIS OF THE FOOT, COMMONLY KNOWN AS MADURA FOOT."

To the Editors of THE LANCET.

SIRS,—I regret that Mr. Hewlett was not present at the meeting of the Pathological Society when I showed two specimens of Madura disease in the hand and foot, as had he been present he might have saved himself the trouble of criticising "statements which I have been reported to have made."<sup>1</sup> On the meagre evidence of a short report he credits me with having said "actinomycosis bovis cannot be stained by Gram's method unless the saponaceous and calcareous matter be first removed." I certainly did not make any dogmatic statement of this nature. What I did say was, "that at times the fungus masses are so calcified (or saponified) that it is impossible to recognise them as actinomyces until the calcareous (or saponaceous) matter has been removed." This was meant to apply not to actinomycosis bovis alone, but to actinomycosis generally, whether bovis, suis, or hominis. Anyone who has had extensive experience of actinomycosis must have met with cases not unfrequently where no fungus structure could be made out on account of advanced calcification, and where after careful treatment with hydrochloric acid and alcohol the typical structure of the ray-

<sup>1</sup> Medical and Chirurgical Transactions, vol. lix., p. 186.

<sup>2</sup> Clinical Medicine, pp 397, 398.

<sup>1</sup> THE LANCET, July 2nd, 1892, pp. 18 and 19.

fungus was beautifully exhibited. This is especially common in the pig and the calf, but applies equally to man and the ox. When, therefore, Mr. Hewlett asserts that in "all" cases of actinomycosis bovis Gram's method, with or without previous decalcification, will give brilliant results, I can only explain this on the assumption of a limited experience on his part or of extremely good fortune. When calcification is advanced there is in fact nothing left to be stained by Gram's method, and we can only hope after decalcification to find the mycelial elements which enable us to diagnose the nature of the affection by means of appropriate stains. There are also other inaccuracies in Mr. Hewlett's paper. It must be many years ago that there was the slightest "hesitation in fully recognising the identity of actinomycosis hominis and actinomycosis bovis." For shortly after J. Israel's researches this identity was acknowledged. Whether the fungus is one and the same for the two forms is an open question even now; we may have to deal with varieties of the same species. The difficulty in recognising the identity of mycetoma and actinomycosis cannot and does not lie "in the presence of a network of filaments and the apparent absence of the club-shaped bodies," but it lay in the apparent dissimilarity of the yellow and black forms of the Indian fungus. This latter circumstance has always been the obstacle to accepting Dr. Vandyke Carter's view that mycetoma is a parasitic disease. As a matter of fact the filamentous network in the yellow form was not clearly recognised by Dr. Carter himself, while almost every observer acknowledged its presence in the black form. In a paper which will shortly appear I hope to give unequivocal proof of the actinomycotic nature also of the black variety of mycetoma; a specimen of this form, obtained from the St. Bartholomew's Hospital Museum, showing both clubs and mycelium beautifully.

As far as my experience goes—and this is the usual experience—in cattle the clubs are absent as frequently as in man. But are the rays of any importance in the diagnosis of the fungus? By rays or clubs I mean with others the well-known hyaline fringes in which the mycelial filaments disappear. I cannot understand on what or whose authority Mr. Hewlett asserts that "in cattle the rays readily stain with Gram's method, while there is a central area which as a rule remains unstained." In actinomycoses, whether in man or in cattle, the central mycelial zone, the true and typical fungus elements "always" stain with Gram's method, but the hyaline clubs "never" do; in fact they refuse any nuclear stain. In older specimens we find that the filament which disappears in the ray is often distinctly clubbed, and naturally stains with aniline gentian violet, but these club-like endings are not what we call "rays or clubs." The pleomorphism, as I also pointed out at the Pathological Society, was established by Israel, Wolf, Bostroom, and others some years ago; but this pleomorphism does not apply to the rays, for it is now acknowledged by all competent mycologists that the hyaline rays are of no morphological or biological importance, and are probably due to some degenerative changes. The extraordinary differences in the staining reactions of the human form from those of the bovine form are certainly new, and require confirmation. Yet another inaccuracy I must draw attention to. Mr. Hewlett speaks of "the apparent absence of the club-shaped bodies in Madura disease." This assertion is perhaps excusable, as in his "one" specimen they seem to have been indistinct. As a matter of fact, as I pointed out at the same meeting, in most cases the clubs are so very well marked and so gigantic, compared with the forms met with in actinomycoses more familiar to us, that it led me to believe that the Indian fungus is not identical with the European form—perhaps a variety of the same species. Drs. Lewis and Cunningham also generally observed tall, fringe-like processes.

In a future publication, to which I have already alluded, I shall enter more fully into the morphology and biology of the Indian fungus and its relation to our forms of actinomycoses. I felt it incumbent on me to correct a few statements which "report" laid at my door, and also with a concluding word to correct yet another statement which I am reported to have made—viz., "that Madura disease is undoubtedly due to a fungus, and that this fungus is identical in its staining reactions with actinomycoses." As in my forthcoming paper I am giving Dr. Carter all the credit he merits for his original suggestion as to the identity of the Indian and European diseases, I hope it will not be thought that I am attempting to claim priority when I reply that at the meeting of the Pathological Society I said that the fungus found in the yellow form of

mycetoma was not only "tinctorially" but also "morphologically and biologically" a form of actinomycoses. At that time, however, I had no absolute proof as to the exact relation existing between the ochroid and the melanoid masses, and could not go further than suggest the actinomycotic nature of the black variety, which now, as I hope to show, thanks to the kindness of Mr. Edgar Willett, who supplied me with the necessary specimens, is likewise established. Other inaccuracies of Mr. Howlett with regard to literary references and the morphology of the fungus I shall pass over, as they are outside the purpose of this letter. I apologise for having occupied so much space, but I found it necessary to defend myself against a criticism based on a mere "report," which might have been obviated if Mr. Hewlett had thought fit to learn my actual statements at their proper source.

I remain, Sirs, yours truly,

A. A. KANTHACK, M.B., M.R.C.P.,  
John Lucas Walker Student in Pathology,  
Cambridge University.

Cambridge, July, 1892.

## PUBLIC HEALTH AND THE NEW PARLIAMENT.

To the Editors of THE LANCET.

SIRS,—It has long been admitted that a Minister of Public Health would be a desirable addition to the Cabinet. Would not therefore the appointment as President of the Local Government Board of some suitable medical M.P. to an extent accomplish this. Such an appointment might eventually lead up to the creation of a special Minister of public health. The time being opportune I have ventured to draw attention to the question, trusting the opinion of the profession will be forthcoming on the matter.

I am, Sirs, yours faithfully,

July 12th, 1892.

C. E. ABBOTT, L.R.C.P.I., M.R.C.S.

## DANGERS IN RESCUING THE DROWNING BY THE POLE ("AXE") DRAG.

To the Editors of THE LANCET.

SIRS,—It is alleged that in 1884 an unfortunate foreigner, who had tumbled into the water at Havre, whilst his rescue was being attempted by an intended life-saver armed with the clumsy, cumbrous pole-drag, or say rather "pole-axe" drag (as still recommended by our Royal Humane Society), was fatally struck on the head by the well-meaning rescuer. The Royal Humane Society's practically non-portable pole-drag measures 19 ft. 10 in. in length. Its metal pole-head is about 20 inches across, weighing 3 lb. 10½ oz. This head terminates in three double sharp-pointed hooks or flukes. This pole-drag, with its long 18 ft. ash-pole, weighs about a further 7 lb., so, in all, the present pole-axe-drag of the Royal Humane Society weighs approximately about 11 lb. But in using it, as the chief weight is at the bottom, the leverage or pendulum swing practically brings out a still heavier weight. I am anxious to learn if any of your correspondents can kindly inform me of other fatal accidents alleged to have occurred in attempts to rescue the drowning by the unwise use of the pole-axe-drag of the Royal Humane Society. Lieutenant Brunel has invented a pocket life line having thirty yards of cord. Its grapnel and float only weigh 5 oz. He has also invented a coastguard life line with a grapnel weighing 4½ oz., a long wooden float serving as bobbin or reel, weighing 2½ oz., and further 46½ ft. of stout cord weighing 5½ oz. or in all 12½ oz., whilst the leather case and strap weigh 4½ oz. Therefore the entire apparatus, including the case, weighs only about 17½ oz. It is to be hoped that the Brunel system of life-saving will be adopted and introduced into this country, where it is neither patented nor protected. Instead of the former dangerous pole-drags, upwards of 3000 Brunel life lines are now used in France saving over 250 lives a year. Invented in 1874, the Brunel portable life lines have already rescued upwards of 1300 lives in France and her colonies. The cost of the apparatus, though infinitely more efficient and portable, amounts in France to less than a third of the price charged for the apparatus at present recommended by the Royal Humane Society.

On June 13th, 1892, at the Swimmers' Life-saving Society, I exhibited, side by side, the life-saving appliances of the Royal Humane Society and those also on the Brunel system.

The latter were generally approved. In a subject of such vital importance as the rescue of the drowning, it is for the public, who are the patrons and subscribers of the Royal Humane Society, themselves to decide which system is the more efficient and economical.

I am, Sirs, yours faithfully,  
J. LAWRENCE HAMILTON, M.R.C.S.,  
Late Honorary President, Fishermen's Federation.

Brighton, July 11th, 1892.

## HEALTH EXHIBITION IN NOTTINGHAM.

To the Editors of THE LANCET.

SIRS.—Our scheme for holding an exhibition of sanitary appliances in connexion with the annual meeting of the British Medical Association in Nottingham, and under the joint Patronage of the association and the Nottingham corporation, seems likely to prove a success. Thirty-six important firms, including Messrs. Allen, Anidjah, Billington, Bostel, Chorlton, Cliff, F. Cooke, Danks, Duckett, Farmiloss, Foster and Cooper, Henry, Hughes and Lancaster, Jennings, Longford (bedding) Co., Merryweather, Parker and Hassall, Sanitas Co., Sollory and Son, Tylor and Sons, Watts and Whitfield have engaged spaces and paid their deposits. The stalls are 420 feet in length and have a uniform width of eight feet. As already announced the Nottingham corporation have lent the covered and wood-paved yards (measuring 100 feet square) at the rear of the Guildhall and are laying the necessary water mains. The patent jointed drain pipes of Messrs. Parker and Hassall will be laid under the stalls and connected with the nearest street sewer. This complete system of water supply and drainage will enable all working hydraulic apparatus to be shown in operation. The president of the British Medical Association, with the Mayor of Nottingham and Sir Walter Foster, will perform the opening ceremony at 11 A.M. on July 26th. Certificates of merit in three classes will be awarded to deserving manufacturers or inventors. Twelve representative gentlemen from London and the provinces have consented to act as judges of exhibits.

I am, Sirs, yours faithfully,  
Nottingham, July 11th, 1892. PHILIP BOOBYER, Hon. Sec.

## THE FRENCH WORKMEN'S SANITARY CONGRESS.

(FROM OUR SPECIAL CORRESPONDENT.)

THE third sitting of the Congress was presided over by M. Audinet, delegated by the Municipality of Châtelleraut, with delegates of the Paris and the Angers Labour Exchanges as vice-presidents.

M. Prudent Dervillier, member of the Paris Municipal Council, reopened the discussion on the food of the working classes. He complained of the insufficiency of the French law with regard to the prevention of adulteration. The analysis of articles offered for sale as food must be made through inspectors appointed by the police; thus nothing was done except under the direction of the Prefect of Police. Sanitary reformers took no initiative in the matter. It was not necessary to insist on the evils that result from leaving everything to the initiative of the chief police official, who was not of necessity a competent hygienist. It was a subject for which the working classes should demand special legislation. There should be penalties sufficiently severe to act as a deterrent on those who sought to adulterate food. Then there should be a service of inspection that did not depend exclusively on the Prefecture. The local authorities should have a voice in the matter and consumers ought to possess the means of obtaining an analysis of a suspected article without having to pay an extravagant fee. On all these questions the example of the English Legislature was well worth studying. The English laws against adulteration were far from perfect, but they were infinitely superior to those existing in France. There were now forty-two public analysts for the metropolis of London, whereas in Paris there was only the one municipal laboratory. As the number of analyses made increased the proportion of articles found to be adulterated decreased. In 1872 the proportion of articles proved to be adulterated was equal to 26 per cent. of those that were examined and in 1880 it was only 17.47 per cent. The English law sanctioned the

imposition of heavy fines and in some cases of imprisonment with hard labour.

If in England results which, though not perfect, served as an encouraging example had been attained, it would be a great mistake to imagine that this was in any way due to the initiative of the English Government. It was due, on the contrary, to the courageous, bold initiative of individual Englishmen. It was not the custom of the Possibilist party to praise individuals, and they were on principle strongly opposed to all forms of hero-worship. There were circumstances when it was useful to point out what one man could do when inspired by the love of the public good. It was impossible to deal with the question of the prevention of food adulteration in England without describing the initiator of this great reform, the late coroner for Middlesex, Mr. Wakley, M.P. Besides, no name could be more appropriately mentioned at such a Congress as the late Mr. Wakley was one of the early champions of the people's cause. It was as far back as 1850 that Mr. Wakley began his campaign. Then adulteration was so much the practice, even among what were considered the most respectable tradesmen and manufacturers, that there was good reason to believe the death-rate was seriously affected. The late Mr. Wakley took upon himself alone to break down this dangerous system of fraud and robbery, though warned by all his friends that such an unequal struggle would entail his ruin. He established a chemical laboratory, sent two persons to buy samples, and, so that his good faith should not be doubted, divided these samples and left one-half in a sealed packet with the tradesman. He then published in his journal, THE LANCET, the result of the analysis. The tradesmen thus detected and denounced were thrown into a wild state of terror and indignation. But the public gave enthusiastic support. Finding that the law was of no service several tradesmen armed themselves with sticks and lay in waiting; but Mr. Wakley had the advantage of being an athlete, and in this respect also had the best of it. French workmen were too indolent and wanting in personal initiative; they were always afraid to complain and were for ever waiting for the Government to come and help them. For this reason the history of Mr. Wakley's endeavours was a useful example. Mr. Wakley had shown that, for instance, out of twenty samples of tea, twelve were false and mixed with poisonous substances. Even opium and other medicaments were adulterated. Of course coffee, pepper and numerous other articles offered a wide field for fraud. They now wanted to render justice to the memory of the man who made these facts matters of public notoriety, who had raised public opinion and had created such an agitation that the government of England was compelled to legislate on the matter. The son and grandson of the late Mr. Wakley were now continuing in these good traditions. It was most important that such independent organs as THE LANCET should exist. The speaker wanted to particularly call the attention of the Congress to the position of the proprietors of THE LANCET. They considered themselves in honour bound and pledged themselves to have no business or financial interest whatsoever in the matters that might be mentioned in the journal. Thus THE LANCET was absolutely independent and free to criticise all and every one. It was a great misfortune that no such independent organ existed in France. All the French papers had business interests to promote and could not follow suit and create a movement such as had arisen in England and which had resulted in the Food and Drugs Act and the Sanitary Act of 1875. Had such a thing been possible in France the lives of thousands and thousands of French workers would have been saved. Yet everyone present at the Congress might attempt, though of necessity on a smaller scale, to follow the example given by the late Mr. Wakley and boldly attack the adulterators. "Let us follow the example of this good English citizen who created the movement that rendered legislation possible and brought about the adoption of those English laws which, with all their imperfections, have nevertheless given some guarantee that the food sold is wholesome, and which have to a notable extent reduced the prevalence of adulteration. We shall then have better food and with better food wiser minds. We shall then be able to judge better and act with greater ability. The workers will more successfully study the causes of their poverty and be in a better position to solve the social problem."

This speech, of which I have given but a summary, was greeted with more than the usual applause. M. Fabré, a journeyman baker from Versailles, followed. He thought the Congress had not given enough attention to the question

of the spoil or inferior flour which was used for bread. At the military and other depôts such deteriorated flour was sold at a very low price. What became of it? Measures should be taken to see that it was not used for human food and that it should only be given to cattle. With regard to the 10 per cent. of water over and above the normal quantity so often found in bread the speaker did not think this was added purposely. It was far more profitable to reduce the cost of labour. Journeymen bakers were made to load the oven so frequently that they had not the time to knead the dough properly. Then, as a further economy, the loaves were crowded so close together in the ovens that there was not space enough to bake them properly. To this was due the high percentage of water found. Men who worked fifteen and sixteen hours in a day could not be expected to make bread well, that is carefully and laboriously. The hours of labour should be limited and the output per man per hour very much reduced; then the bread would be well and wholesomely made. The delegate agreed that the municipality ought to compete against private bakeries, but it would be a mistake to create one large central municipal bakery. The cost of delivering the bread might amount to 10 per cent. of the total cost of producing it, while that of labour would not be more than 6 to 7 per cent. It was much more practical to have a number of small local municipal bakeries and thus the expense of delivering the bread would be very materially decreased. For about £100,000 the municipality could start 120 different bakeries in various parts of Paris, where the journeymen bakers would not be overworked and where genuine, cheap bread could be sold.

M. Heppenheimer, municipal councillor, was anxious that an independent and purely scientific authority should be organised to check adulteration instead of the present police authorities.

M. Caumaud, municipal councillor, apologised for the small wine dealers. They were not the worst culprits, though they certainly did add water to their wine. It was the intermediary merchants who should be watched.

Dr. Paul Brousse, municipal councillor and reporter on this question, urged that the law protected the wholesale merchants while prosecuting the retail dealer. It was only when an article was offered for sale that proceedings could be taken, so it was quite safe to adulterate in a wholesale manufactory. At the wine docks of Bercy the cost would be too great, in consequence of the entrance dues, to adulterate wine. The intermediary firms were the real culprits. They advanced small sums to individuals so that the latter might open retail wine shops. The sum advanced was generally insufficient, the retailer had to borrow more, and in doing so had to accept adulterated wines. When the retailer was caught it was the intermediary merchant who paid the fines and continued to supply bad wines. The law should be able to trace the wine back to this intermediary and thus reach the real culprit.

The Congress now proceeded to discuss the second question—namely, the feeding and rearing of workmen's children, or as it was put, the milk question—*la question de l'allaitement*. M. Caumaud reported and said he did not propose to deal with children above the age of two years. The high rate of infant mortality was due to our present bad social organisation which tore children away from their mother's breast. The number of mothers who abandoned the hope of suckling their own children was daily increasing. The child which was the product of a difficult gestation due to excessive toil, prolonged till the eve of its birth, came into the world weak and unhealthy. The mother, anxious to return to the factory or the workshop, sent the infant off to some distant provincial baby farm, where it was almost certain to die. A great step had been accomplished by the humanitarian law of May 23rd, 1874. This law, instituting a system of inspection over all who had charge of children, was more rigorously applied in the neighbourhood of Paris than elsewhere and statistics showed with what beneficent results. The mortality of infants under one year old was 18.44 per cent. in the period from 1868-1872. It fell to 16.72 per cent. for the years 1878-1882, and does not now exceed 15 per cent. This was a clear demonstration of the advantage of legislative interference. M. Caumaud insisted on the duty of mothers to suckle their own children. In the upper classes mothers sought to avoid this responsibility. They were too fashionable to suckle their own children and gave them over to the care of hired wet nurses. This was against nature's laws and should not be allowed. As a result

it often happened that either the nurse contaminated the child or the child contaminated the nurse. Many peasant women had caught syphilis through nursing Parisian children. The results of artificial feeding were even more disastrous. In Paris of the assisted infants of the poor the proportion of deaths in 510 of children fed from the breast was 4.90 per cent. and of 669 fed from the bottle 9.56 per cent. In the suburbs of Paris out of 1634 infants fed from the breast 6.36 per cent. died, and out of 1389 fed from the bottle 12.45 per cent. died. M. Caumaud urged that long tube bottles should not be allowed. He proposed that as £600,000 had been spent to build the prison of Nanterre for criminals and vagabonds, at least £400,000 might be spent to create near Paris a vast establishment which would serve as a maternity, where mothers could live with their infants for at least two months after the birth of the child, instead of being driven away in five days, as is done at the hospitals.

Madame Bertier did not like the idea of such vast agglomerations. Nature demands that children should remain with their mothers, and if mothers could not afford to keep their children with them, then sufficient out-door relief should be given to avoid the necessity of separating mother and child.

M. Vallet protested that this was true enough in principle, but in practice many mothers were much too poor and too ignorant to rear their own children. The recommendations given with regard to the precautions for the milk would not be understood; and till such time as the lower labouring classes were better educated and better paid institutions such as had been suggested by M. Caumaud would render great service. Naturally it would be better to keep mother and child together, on condition that the mother did not live in some overcrowded, filthy and insalubrious garret.

The Congress then adjourned.

Paris, July 11th.

## MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

### *The Infirmary and Owens College.*

FOR a long time the question has been agitated whether the Royal Infirmary should accept a site on the Stanley Grove estate, which has been given to the Owens College by the trustees of the late Sir Joseph Whitworth, and should thereon erect a new infirmary. It has been urged that the present building is insufficient and antiquated, and that the site offered by the Owens College would be more suitable, being quieter in its surroundings and about a mile and a half from the centre of the town, for building a new hospital, and that it would be rather more convenient for students inasmuch as it is nearer to the Owens College. On the other hand, plans have been prepared for the enlargement of the Royal Infirmary or the erection on the same site of a new hospital with greater accommodation. These proposals will shortly be laid before a meeting of the trustees of the infirmary. Meanwhile the board of management have refused the offer of the Owens College for a building site on their property. Any scheme for increasing the bulk of buildings on the present site, which is in the centre of the city, will be strongly opposed by many people, who consider that the ground now surrounding the buildings should be preserved as an open space for the general benefit of the town.

### *The late Professor Schorlemmer*

Professor Schorlemmer, F.R.S., who held the chair of Organic Chemistry in the Owens College, died on June 27th. The deceased gentleman, who will be long remembered by many old medical students, became attached to the College in 1861 as assistant to Professor Roscoe, and in 1874 was appointed Professor of Organic Chemistry. He wrote a manual on the chemistry of the carbon compounds and, together with Professor Roscoe, an extensive treatise on chemistry.

Manchester, July 6th.

## NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

### *The Health of Newcastle City.*

DR. H. E. ARMSTRONG (our medical officer of health) has just issued his annual report on the sanitary condition of this city, with tabular reports of the sickness and mortality of the

past year. The returns show reduction in the general rates of births and deaths per 1000 population of all ages, and the former have fallen from 40·5 in 1890 to 35·7 in 1891. The latter have declined from 26·2 to 23·6, notwithstanding the increased mortality from the last six weeks of the year, which attained the average of 35·8 per 1000. The rise is all the more striking from the fact that the average rate for the preceding six weeks to Nov. 21st was only 21·9 per 1000. The principal factors of this abnormal state of things, Dr. Armstrong says, were undoubtedly diseases of the respiratory organs with or without influenza. By far the most fatal infections have been measles and whooping-cough. These together caused 307 of a total of 478 deaths from zymotic diseases and diarrhoea. Small-pox has been entirely absent, and no death from typhus fever has been recorded during the year. Dr. Armstrong shows very forcibly that measles (of which the sanitary department has no official knowledge except from the registrar of deaths, when it is too late to benefit by the information) causes four times as many deaths as scarlet fever. Dr. Armstrong, in his painstaking report, shows how the various sanitary departments are working for the good of the city and instances the work done by the inspectors of nuisances of the common lodging-houses and of the active proceedings of the inspector under the Adulteration Acts.

#### *Sunderland: the New Eye Infirmary.*

The foundation stone of the new building for the Sunderland and North Durham Eye Infirmary has been laid by Mrs. Backhouse. The building is to be two storeys high and provides accommodation for sixteen patients. On the ground floor is a waiting-room to hold 200 persons. This is situated behind the Board-room, from which it is separated by a sliding wood partition which enables the two rooms to be turned into one for the purpose of concerts &c. The general form of the plan is an H, which gives the best possible light and ventilation with the greatest economy in construction. The architect is Mr. J. Wardle Donald of South Shields and the cost will be £4590.

#### *Carlisle: Curious Medico-legal Case.*

A case was tried at the late Carlisle Assizes before Mr. Justice Denman which possesses many points of medico-legal interest. It was sought by an action to set aside the will of a Mrs. Wilcox made in 1884. She died in 1885 at the age of seventy-five. It was shown that at one time she was insane and imagined she was related to the Countess of Derwentwater and Lord Bute and conveyed the whole of her property to Dr. Goss, Bishop of Liverpool; but she still collected her rents. Dr. Goss had the property reconveyed back to Mrs. Wilcox again. At another time she conveyed all her property to the Jesuits and in the same year made her will. In short, she was frequently settling and unsettling her property. It was admitted that she was an inmate for a time in 1864-5 of the Southern Counties Asylum at Dumfries, her mind becoming unhinged after the severe illness and death of her husband. On the other hand, it was shown by solicitors and others that she was generally a shrewd and even very intelligent lady, who knew very well what she was about. The learned judge in summing up said a person might be insane to a certain extent and yet have a mind sufficiently sound for the purpose of disposing of property. The fact that a person had once been in a lunatic asylum must not of itself be taken as conclusive evidence that the person was incapable of making a will and they must judge of a person's sanity by collateral points, by documents, and by other circumstances. The jury, after a consideration of twenty minutes, found for the validity of the will.

#### *A Long Service.*

At the last meeting of the Weardale guardians Mr. Bourne, surgeon, wrote tendering his resignation as medical officer on account of physical infirmities. He said that he had served forty-four years and asked to be recommended for the usual pension. His resignation was accepted with regret by the guardians and the question was adjourned for the next meeting, with the object no doubt of having a full one and a stronger force in the recommendation to the Local Government Board.

At West Hartlepool on Sunday there was a brilliant afternoon to favour the Sunday Hospital demonstration, and the attendance and procession of the Friendly Societies are said to have been the largest on record; it is hoped that the collection will be in proportion. Addresses were given by the Mayor (who presided) and other gentlemen in favour of the fund.

Newcastle-on-Tyne, July 12th.

## SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

### *Edinburgh Medico-Chirurgical Society.*

THE last meeting of the session of this Society was held last week, Dr. Joseph Bell, the president, being in the chair. Dr. James Carmichael showed a Brain with Abscess of the Cerebellum secondary to internal ear disease, and Dr. James showed a Sphygmometer. There were four papers before the meeting for discussion, the first dealing with Electro-diagnosis by means of the Urine, by Dr. Dawson Turner, who gave an outline of a large number of observations he had made on the subject, the urines being from different classes of cases, and the general conclusion being that the degree of resistance depended mainly on the salts present. [We print a *résumé* of these observations in another column.—ED. L.] The next paper was by Dr. G. A. Gibson, on the Antiseptic Treatment of Pernicious Anæmia, and was a further contribution to the discussion on Pernicious Anæmia which had taken place at the preceding meeting. The communication was based upon a well-marked case of the disease which had resisted treatment by arsenic and in which  $\beta$  naphthol was given, following a suggestion of Dr. W. Hunter. During the administration of the drug in doses of two grains thrice daily the blood improved in corpuscular richness, and two or three months after its commencement stood at 2,320,000 per cubic millimetre and the general condition had correspondingly improved. For purposes of comparison it was also given to an ordinary case of anæmia in a young woman, and in this case also there was a gradual improvement in the corpuscular richness of the blood. The paper gave rise to considerable discussion, which was taken part in by members of the Society who had not been present at the previous discussion, but no further points of special interest were brought out. The next communication was by Dr. J. A. Gibson and Dr. Lockhart Gillespie, entitled "Lessons from the Development of the Heart," and consisted of a lantern demonstration of photographs of transverse sections of the heart showing the thickness of the walls of the ventricles at different periods of fetal life at different ages after birth, and in some diseased conditions; but the discussion on the practical bearings of these was deferred. The last paper, Notes on Indian Enteric Fever, by Surgeon-Captain C. H. Bedford, Bengal Medical Service, was taken as read, and ordered to be published in the Transactions of the Society.

July 12th.

## IRELAND.

(FROM OUR OWN CORRESPONDENT.)

### *The late William Colles, M.D., F.R.C.S.I.*

AT a meeting last week of the governors of the Rotunda Lying-in Hospital the following resolution was adopted unanimously: "That the board desire to record their regret at the death of the late William Colles, who for many years discharged the duties of consulting surgeon to the Rotunda Hospital." A copy of this resolution has been forwarded to Mrs. Colles.

### *Sir Patrick Dun's Hospital.*

A garden *fête*, under the patronage of the Lord Lieutenant and the Countess of Zetland, will be held this day and tomorrow in the grounds of Gortmore, Dundrum, in aid of this excellent institution. The Blue Hungarian Band and two military bands will add to the attractions of the *fête*.

### *Royal College of Surgeons.*

On Friday, the 8th inst., a portrait and bust of the late Robert McDonnell, M.D., Fellow and ex-President of the College, was unveiled by his Excellency the Lord-Lieutenant. Sir John Banks, K.C.B., said on behalf of the subscribers that he begged to present the portrait and bust to the College. The object was that the esteem in which Dr. McDonnell's personal worth and professional labours were held should be perpetuated. He received his education in their ancient University and followed his father in choosing the profession of medicine. He presided over that College and also over the Royal Academy of Medicine, and his name and fame went beyond this country, for he received the much-coveted distinction of a Fellowship of the Royal Society. Dr. McDonnell rose to the very highest rank in the profession, and it was expected that having regard to his

position, his services and all the good that he did to the State in peace and war, and as a member of several Royal Commissions, that he would receive some State recognition. This was the desire of the public and of the profession, and the Viceroy was of the same opinion. In conclusion, he had on behalf of the subscribers to give the portrait and bust to the College. The presence of his Excellency the Lord-Lieutenant added dignity to their proceedings and showed his kindly feeling and sympathy with their profession. The President, on behalf of the College, having thanked the subscribers, his Excellency made a few appropriate remarks, in the course of which he said that Dr. McDonnell was not only a member of every scientific institutions in Dublin, but was one who gave up a position in Steevens' Hospital and who of his own accord volunteered to go into the dangers of the trenches in front of Sebastopol, where he did signal and extraordinarily good services to his country. He trusted that the bust and portrait, both of which would be admired as works of art and appreciated because of the gentleman to whom they bore a resemblance, would keep his memory alive in many generations of Irishmen.

#### *Graduates' Memorial, Trinity College, Dublin.*

A meeting in reference to the proposed graduates' memorial took place during the tercentenary week and was presided over by Lord Rosse. Up to the day of meeting a sum of £6500 had been received or promised, but since then I learn that the fund now available, the major portion of which has been invested in Government stocks, amounts to a much larger sum, and it is confidently expected that £10,000 will be realised before many months have passed. The Board of Trinity College have promised a site within the College, the site to be determined by the amount of contributions received. The proposed building is intended when completed to accommodate the various societies which meet within the walls of the university. The following resolution was adopted: "That the graduates of the University of Dublin desire to express their warm thanks to the Board of Trinity College for the assent accorded by them to the establishment of a Dublin University Union within the precincts of Trinity College as the graduates' memorial of the tercentenary of the College and the University.

#### *Ulster Medical Society.*

At the annual meeting held at Belfast on July 8th, the report of the Council was submitted, from which I learn that the Society is in a very flourishing condition, there being a larger number of members than at any previous period of its history. The following office-bearers were elected for the coming session:—President: Dr. Whitaker. Vice-Presidents: Dr. John W. Byers and Dr. Barnett. Treasurer: Dr. Charles Kevin. Secretaries: Dr. McCaw and Dr. Calwell. Librarian: Dr. Cecil Shaw. Pathological Secretaries: Dr. John Campbell and Dr. McQuitty. Members of Council: Dr. J. A. Lindsay, Professor Sinclair, Dr. Ferguson, Dr. Dempsey, Dr. E. C. Bigger and Dr. W. M. Killen.

#### *North of Ireland Branch of the British Medical Association.*

The annual meeting of this Society was held in Lisburn on Thursday, July 7th. Mr. St. George, surgeon to the County Antrim Infirmary, president, occupied the chair. After several interesting medical communications had been brought before the meeting Dr. J. Walton Browne (Belfast) was elected president for the ensuing year. After the conclusion of the meeting Mr. St. George entertained fifty members of the North of Ireland branch at luncheon in his house at Lisburn.

Mr. J. E. Kenny coroner for Dublin, has been elected M.P. for the College Green Division of Dublin by a considerable majority.

The session for the present summer has now ended both at the hospitals and at Queen's College, Belfast.  
July 12th.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

#### *The Epidemic of Cholera in Paris and its Environs.*

WHEN last week I wrote about the outbreak concerning which so much anxiety is felt in this city, I gave it the name of cholérine. I regret that further inquiries compel me to modify its nomenclature and to designate it "cholera

morbus." Such is undoubtedly, I believe, the real nature of the epidemic, and no amount of reticence on the part of the authorities can alter the significance of the facts. The epidemic has manifested itself at two principal centres, but situated "down-stream" and located along the great curve described by the Seine around the peninsula of Gennevilliers. The first centre, comprising Courbevoie, Suresnes, Asnières, Colombes and Argenteuil, is, with the exception of the last, situated within the loop, while the second-mentioned village centre is on the right bank, and includes Aubervilliers and St. Denis. It cannot be denied that, however sluggish the disease may be in its rate of extension, the mortality is alarming amongst those attacked, a fatal result often occurring in a few hours after invasion; and although the capital itself has on the whole escaped, a few cases occurring amongst Parisians have for the last few days been registered. Thus, on Saturday last, three cases were reported—one in the eighteenth and two in the nineteenth arrondissements. On Sunday there were eight cases in different arrondissements. Of these eight cases, however, there is reason to believe that five at least were cases of fright, the symptoms being trifling. On Monday two deaths were registered, both victims being infants. On that day four cases were admitted into the Lariboisière Hospital. Several fatal cases are reported from Aubervilliers, St. Denis, Courbevoie, Levallois, Asnières, St. Ouen and at Ivry, where the disease has made its appearance in the large Hospice des Vieillards. Its appearance at Ivry and at Noisy-le-Sec, both situated up-stream, cannot well be attributed to the drinking of contaminated Seine water. Is the disease really Asiatic cholera? In an able article published in the current number of *La Médecine Moderne* Dr. Talamon, the talented editor, replies unhesitatingly in the affirmative. He regards it as proved that the comma bacillus has remained latent until lately in the soil of the Plaine St. Denis since the year 1884, the date of the last epidemic. He recalls the fact that the cholera of 1884 imported to Toulon made its first appearance in the neighbourhood of Paris at St. Denis and Aubervilliers. He observes great similarity between the present epidemic and the outbreak of cholera in 1890 at Puebla de Rugat. In both instances there was no importation from abroad, both occurred at the same time of the year and both were characterised by slow extension and endemicity. The survival of the cholera bacillus in the soil since 1884 is explained by the researches of Huoppe, Wood and Lustig. These savants tell us that the cholera bacillus is both aerobic and anaerobic, according to its habitat. In the intestinal canal it is anaerobic. Its virulence is here very intense; but it is, on the other hand, more vulnerable to the destroying action of chemical agents. Hence the importance of the prompt disinfection of choleraic stools. In the superficial layers of the soil the bacillus is aerobic and its vitality becomes greatly increased. Its power of resistance is further increased by the formation of jointed spores—the "zoogloes arthrospores" of Huoppe, which, forming a kind of thick viscid network, offer protection against the influence of putrefaction and desiccation. Combined dryness and heat favour its growth, and these atmospheric conditions have been present for the last two months. It further appears that at Aubervilliers extensive road repairing has been in progress for a considerable time, thus setting free colonies of microbes, which, finding their way into the drinking water, spread the disease. The comparative benignity of the outbreak is explained by the observation of Hauser, to the effect that if the bacillus lying latent in the soil resumes its morbid properties in contact with the air, it has nevertheless lost the power of reproduction so characteristic of the microbe of direct Asiatic origin. What measures are the authorities taking to stem the choleric tide? A first step has been taken by the Prefect of Police in the appointment of a sanitary inspection committee, which comprises amongst its members such well-known names as Colin, Dujardin-Beaumez, Proust, Levraud (President of the Sanitary Commission of the Municipal Council) and Brousse. To these names have been added those of Drs. Thoinet and Dubauf, both accomplished bacteriologists, together with Drs. Deschamps and Touvenin. These latter gentlemen, each accompanied by a member of the committee, have already begun their rounds in the infected suburbs. The Assistance Publique has determined to utilise the temporary hospital situated in the Bastion No. 36 for cholera cases, such a step being taken in order to prevent as far as possible the introduction of the infection into the

interior of Paris. A sum of 42,500 fr. has been voted by the Conseil Général of the Seine Department in aid of those communes that are willing to make an outlay in the purchase of filters and sterilising apparatus. I may supplement the above information by stating that Dr. Chantemesse, one of M. Pasteur's principal assistants, is decidedly of opinion that we have to deal with true Asiatic cholera. This I have from a private source. So far as I am aware, no cases have as yet been reported from any of the barracks.

*The Composition of Dr. Brown-Séguard's Gland Juice.*

At the last meeting of the Académie des Sciences M. Gautier announced that Professor de Poehl of St. Petersburg had succeeded in extracting from the pancreas, thyroid body, ovaries and testes a leucomaine called spermine, having the composition represented by the formula  $C_6H_{14}N_2$ , which he has isolated in the form of crystallised phosphate. A few centigrammes of this base, introduced subcutaneously in the form of hydrochlorate, is said to produce the tonic and exciting effects of Dr. Brown-Séguard's injections, and the discoverer believes that it is to spermine alone that the remarkable results obtained by these injections are due. It appears that spermine possesses great oxidising power, it being capable of rapidly converting, in the presence of gold or platinum chloride, magnesium into magnesia. Under its influence also the nitrogenous extractives of urine are converted into urea. It is pointed out that in Germany spermine is confounded with piperazine, the latter substance being sold for the former.

Paris, July 13th.

## BERLIN.

(FROM OUR OWN CORRESPONDENT.)

*Death of Professor Hermann Nasse.*

PROFESSOR HERMANN NASSE, the oldest member of the medical faculty at Marburg, died the other day. Both his father and his grandfather were medical men of more than average reputation. He was born at Bielsfeld in 1803, studied at the Rhenish Frederick William's University and in Paris, assisted Philipp von Walther in the surgical clinic at Bonn and established himself as a private lecturer there in 1834. In 1837 he was called to the chair of physiology, pathology and veterinary science at Marburg, but afterwards confined himself to physiology. His chief writings are: "Inflammation as illustrated by its Anatomical Results," "Contributions to the Physiology and Pathology of the Blood" (written in conjunction with his father), "The Influence of Nutrition on the Blood," "Lymph and its Formation," and the articles on Blood, Chyle, and Lymph in Rudolf Wagner's "Handwörterbuch der Physiologie" ("Hand Lexicon of Physiology").

*Miscellaneous Items.*

The appointment of Professor Fischer of Würzburg to succeed A. W. von Hofmann as professor of chemistry and director of the first chemical institute in Berlin is now an accomplished fact. He will enter on his new duties next session. He will be succeeded at Würzburg by Professor Victor Meyer of Heidelberg.

Professor Ludwig Andreas Buchner, who occupies the chair of pharmacology at Munich, will retire at the end of this session.

Dr. Zander, private lecturer on anatomy, and Dr. Nauwerck, private lecturer on pathological anatomy, both of Königsberg, have been appointed professors.

The *Allgemeine Medicinische Central-Zeitung* (General Medical Central Journal), the oldest of the German medical journals, passed into the possession of the publisher, O. Coblentz, on the 1st inst. Dr. H. Lohnstein remains editor.

Berlin, July 12th.

## EGYPT.

(FROM OUR OWN CORRESPONDENT.)

*The Medical School.*

LAST February some new regulations came into force for the School of Medicine, chiefly on the initiative of the new director and his energetic English colleague. The students will now undergo a six years' course before their final examination for the diploma and the last two years will be devoted to hospital work almost entirely. Before entrance to

the school they must prove that they are at least sixteen years of age, of good health, and that they have passed successfully the secondary examination of the Government schools. This rule will get rid of all those of miserable physique and of untrained mental growth. Students will pay some £84 for the whole of their school and examination fees, but special reduction may be made in a few cases to those who are considerably richer in intellect than in pocket. This is an advance upon the late system, under which the Government paid all the boys for the privilege of teaching them. But it must be remembered that elementary education was only commenced in Egypt fifty years ago, and that at that time Mehemet Ali Pacha had to take children from their parents by force to fill his new schools. During the first two years anatomy, among other subjects, will be taught in a much more thorough and practical way than before, and during the first four years there will be gradually diminishing lessons in the English language. Pathology, which until lately has been entirely neglected, will be taught in the third year, and students will also for two years be obliged to attend all the necropsies of the hospital. The present appointment as pathologist and head of the bacteriological department of Dr. Kaufmann, ex-assistant to Professor Weigert, has already borne good fruit, and it is to be hoped that his labours may gradually furnish the now empty shelves of the pathological museum. The third-year students attend the out-patients' department, in the fourth year they visit the wards for an hour a day, and they hold hospital appointments during the fifth and sixth years. The lecturers are bound to formulate their course upon certain standard books chosen by a committee of lecturers and examiners. Those chosen for next year are mostly in Arabic or French, with a few English text-books, such as Pagge, Nettleship, Klein, &c. Written examinations are to be introduced for the first time next October. The annual examinations have just been held orally, with a new board composed of eight members, each of whom has the lecturer of the subject associated with him. These eight members are unconnected with the school, though some of them are on the hospital staff, and for the first time they are to receive a small fee. They are appointed for three years and consist of a native, a French, and four English doctors, together with a French and a German chemist. At the recent examination 106 students presented themselves, of whom 53 were referred till October, the failures being mostly in anatomy, midwifery, pathology and hygiene. This is the first time that the examinations have been conducted on any serious principle. The School of Pharmacy has dwindled down to two students, of whom one failed to satisfy the examiners. The medical school for girls was represented by fifteen, of whom ten were successful. The girls' school has recently been placed under the control of an English nurse holding an obstetric diploma, and the girls when not attending lectures are lodged, fed and clothed in the hospital, where they act as under nurses in the female wards. None of these reforms would have been possible without the coöperation of the Minister for Education—an Armenian Pacha of rare intellectual gifts.

*The "Bosphore Egyptien."*

It will be remembered that on May 4th a French newspaper here went out of its way to libel Mr. Milton with reference to various surgical operations. The terms of the libel caused the greatest sympathy with Mr. Milton to be manifested by all those not belonging to the French colony, and great joy was evinced yesterday when the verdict of the judges was announced in the civil action brought against the journal. The case was tried in the Court of Mixed Tribunals here, a cumbersome method necessary in a country where every individual is protected by the laws of his own nation. The case came before five judges, two natives, a Russian and an American, with a German president. The *Bosphore* made no attempt to prove its charges and relied for its sole defence upon further abuse of Mr. Milton and his English and German colleagues. It tried, of course unsuccessfully, to prove that Mr. Milton, because he possesses the L.S.A. diploma together with that of M.R.C.S. Eng., was nothing but a simple druggist. The advocate for the defence, who is also one of the owners of the newspaper, made the wildest and most hysterical statements, and, when taxed by the plaintiff's counsel with direct falsehood, he complained plaintively that he had not been able to find any medical witnesses to support the libellous charges. The judges ruled that the libel was "untrue, defamatory and injurious" and condemned the *Bosphore* to pay all costs and £1025 damages, with interest at 7 per cent.

until paid. The judgment was published yesterday in the *Bosphore* and must also appear, by order of the Court, in an English and Arabic local paper. The condemned parties will of course appeal and the case will be reheard at Alexandria in the autumn. The verdict leaked out a few days before, delivered probably through the native judges, and it is an open secret that if it had not been for the Gorman and American members of the Bench the sum awarded would have been absurdly small. The *Bosphore* in its issue last night devotes two furious columns to the iniquities of the Court and threatens Mr. Milton with future disclosures. So long as there is no comic journal published in Egypt we owe a debt of some gratitude to the *Bosphore Egyptien*.

Cairo, July 1st.

## ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AT a quarterly meeting of the Council held on the 14th inst., the President reported that at a meeting of the Fellows of the College, held on the 7th inst., for the election of four members of the Council in the vacancies occasioned by the retirement in rotation of Mr. Thomas Smith, Mr. Arthur Edward Durham and Mr. George Lawson, of whom Mr. George Lawson did not offer himself as a candidate for re-election, and by the death of Mr. Matthew Berkeley Hill, Mr. Thomas Smith and Mr. Arthur Edward Durham had been re-elected and Mr. John Tweedy and Mr. Frederick Howard Marsh elected members of the Council. These gentlemen made a declaration in the terms of the oath prescribed by the Charter of 1800 and took their seats as members of the Council.

The minutes of the Museum Committee of the 4th inst. were read as the report from that committee and it was agreed that Mr. Burgess, the museum artist, should be employed for a further period of six months.

The Council decided to supply six additional tables for the display of the dissections of human anatomy.

As recommended by the Committee of Management, the West Riding Lunatic Asylum at Wakefield is to be recognised for the purposes of study required by Section 1, Clause 2, Paragraph 13 of the Regulations of the Combined Examining Board in England.

In accordance with the recommendation of the same Committee, it was decided to provide a sinking fund for the Examination Hall and Laboratories, and the subject was referred back to the Committee for elaboration of a scheme.

The reports of the Laboratories and the Nomination Committees were approved, read and adopted.

The following professors and lecturers for the coming year were appointed: Mr. J. Hutchinson, jun., and Mr. B. Pitts, as Professors of Surgery and Pathology; Mr. B. T. Lowie, Mr. C. B. Plowright and Mr. C. Stewart, as Professors of Comparative Anatomy and Physiology; Mr. J. R. Bradford, as lecturer on Anatomy and Physiology; Mr. J. H. Targett was appointed as the Erasmus Wilson Lecturer.

The President reported the holding of the meeting of Fellows after the election of members of the Council on Thursday, the 7th inst.

A letter was read dated the 4th inst. from Mr. E. Octavius Croft, Secretary to the Faculty of the hospital, enclosing an application from the honorary medical staff of the Hospital for Women and Children at Leeds for the recognition of that institution as giving such clinical instruction in gynaecology as is required by the regulations for the examinations for the Membership of the College. The letter was referred to the Committee of Management for their consideration and report.

Mr. J. H. Targett was elected Pathological Curator for another year. Mr. J. B. Bailey was re-elected Librarian.

Mr. Thomas Bryant was re-elected President of the College for the third time. Messrs. C. Heath and A. E. Durham were elected Vice-Presidents.

The members of the various committees were appointed.

It was agreed, on the motion of Mr. Rivington, that a committee should be appointed to consider and report to the

Council on the standing rules, and to submit a revised copy to the Council.

The thanks of the Council were given to Mr. F. G. Hallett for his catalogue of portraits and busts in the Royal College of Surgeons.

The next meeting of the Council will be held on August 1st.

## Medical News.

**EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.**—The following gentlemen passed the Second Examination of the Board in the subjects indicated at a meeting of the Examiners on the 4th inst. :—

*Anatomy and Physiology.*—Thomas S. Bartley, William F. Rawson, Eric G. Storrs and Percy V. Fry, students of Yorkshire College, Leeds; Walter R. Walton, of University College, Liverpool; Thos. F. Woolley, Wilfred Allport, William S. Willmore, Geo. H. E. Bekenn, Eustace B. Bostock, George E. Atkins and Henry W. Pepper, of Queen's College, Birmingham; Subhan Ali, of Lahore Medical School; Edward W. Battle, of Owens College, Manchester; F. H. Humphris, of Edinburgh University and Mr. Cooke's School of Anatomy and Physiology; Francis F. Noonan, of Melbourne and Edinburgh Universities; Alfred Lockhart and Isaac Wood, of Queen's University, Kingston, Canada.

*Anatomy only.*—Charles A. Phillips, Edward H. Phillips and Geo. Y. Myrtle, of Yorkshire College, Leeds; Henry W. Lloyd, of University College, Liverpool; Ernest W. Ormrod, of Bristol Medical School; Herbert A. L. Banham, of Sheffield Medical School.

*Physiology only.*—Geo. R. Sparrow, of University College, Liverpool. Twelve candidates were referred in both subjects, one in Anatomy only, and six in Physiology only.

Passed on the 5th inst. :—

*Anatomy and Physiology.*—Phillip Macaulay, of Yorkshire College, Leeds; R. Howlett-Hayes, of Dublin and Guy's Hospital; Leonard N. Pentreath, of St. Thomas's Hospital; David L. Clay and John Hepworth, of Owens College, Manchester; Alfred K. White, of Dublin; William H. Brown, David Horwich, William G. Thomas and William H. G. Wilkes, of Queen's College, Birmingham; Thomas J. Chidley, of Dublin and Mr. Cooke's School of Anatomy and Physiology.

*Anatomy only.*—Wilbye Cooper, John L. Elliott and Arthur T. Lachmora, of Yorkshire College, Leeds; John T. Barritt and Robert Marshall, of Owens College, Manchester; Frederick A. W. Quay, of Trinity College, Toronto; Bernard P. O'Neill, of Guy's Hospital; Howard P. Kennard, of St. Thomas's Hospital; J. A. K. Griffith, of University College; Edward A. McAnnally, of St. George's Hospital and Mr. Cooke's School of Anatomy and Physiology; Augustus C. Greenwood, of Middlesex Hospital.

*Physiology only.*—William Archer and Walter G. Parkinson, of Yorkshire College, Leeds; Thomas W. W. Boyce, of Bristol Medical School; Frederick A. L'E. Burges and John W. Farndale, of Queen's College, Birmingham; Thomas H. Agnew, of University College, Liverpool; Henry J. Heginbotham, James Worthington, and Samuel Crossley, of Owens College, Manchester.

Nine candidates were referred in both subjects, four in Anatomy only and ten in Physiology only.

Passed on the 6th inst. :—

*Anatomy and Physiology.*—Julian Horn, Tom H. B. Yorath and Harry D. Packer, of Guy's Hospital; John C. Padwick, George Miller and Sydney C. Hounslow, of St. Bartholomew's Hospital; Lewis W. Burrow, of St. Thomas's Hospital; Frederick A. J. R. Brooko, of London Hospital.

*Anatomy only.*—Joseph L. F. de Gannes and Cyrus W. Smith, of University College; Preston R. Wallis, of University College and Mr. Cooke's School of Anatomy and Physiology; Christopher A. A. Coulthard, of St. George's Hospital; Charles F. Stileman, of St. George's Hospital and Mr. Cooke's School of Anatomy and Physiology; Thomas H. Parker and Henry P. Cox, of King's College; Ernest H. Tipper, of Guy's Hospital; Percy L. Blaber, of St. Thomas's Hospital; Alan P. Birch, of Middlesex Hospital and Mr. Cooke's School of Anatomy and Physiology.

*Physiology only.*—Ernest E. Crowther, of Yorkshire College, Leeds; George V. Miller and Frederick P. Duncan, of University College; Walter K. Hopkins, of St. Bartholomew's Hospital; Henry A. Burridge, of King's College; Charles C. Jenkins, of Guy's Hospital.

Fifteen candidates were referred in both subjects, three in Anatomy only and ten in Physiology only.

Passed on the 7th inst. :—

*Anatomy and Physiology.*—Alfred Armer, of St. Bartholomew's and Guy's Hospitals; Cecil F. Gordon, of St. Bartholomew's Hospital; Francis J. H. Cann, of Guy's Hospital; Philip G. Mould, of Owens College, Manchester, and St. Mary's Hospital; Geo. B. C. Blount, of St. Thomas's Hospital; Thomas Lambie, of University College; Arthur G. L. Smith, of Middlesex Hospital.

*Anatomy only.*—John W. Ensor and Morton E. Tresidder, of Guy's Hospital; George W. Brown and William Herbert, of St. Thomas's Hospital; Alexander S. McSorley, of King's College; Thomas S. Pigg and Arthur R. H. Skey, of St. Bartholomew's Hospital; Francis A. Phillips, of St. George's Hospital; Morgan D. Blake, of St. George's Hospital and Mr. Cooke's School of Anatomy and Physiology; Randolph L. Grosvenor, of Cambridge University and St. Mary's Hospital; William G. Noble, of London Hospital.

*Physiology only.*—John R. Benson, of King's College; J. S. Hosford, Ernest G. L. Goffe and John W. Stokes, of University College; Edward J. C. Kennedy, of Victoria University, Ontario; Walter A.

Sharpin, of St. George's Hospital; William A. Carden, of Guy's Hospital; David L. Jones and G. G. Oakeley, of St. Bartholomew's Hospital; A. Stanley-Matthews, of St. Thomas's Hospital; Alfred Carruthers, of St. Thomas's Hospital and Mr. Cooke's School of Anatomy and Physiology.

Nine candidates were referred in both subjects, seven in Anatomy only and nine in Physiology only.

Passed on the 8th inst. :—

*Anatomy and Physiology.*—Frank Lond, of Guy's Hospital; Arnold E. Lovitt, Wm. G. Mortimer and John H. Power, of London Hospital; Richard T. Cesar, of London Hospital and Mr. Cooke's School of Anatomy and Physiology; Malcolm Wheeler, of Edinburgh University and St. Thomas's Hospital; Gordon C. Barker, of King's College; William F. Cross, of St. Bartholomew's Hospital; L. E. Callender and Robert W. Dodgson, of St. Mary's Hospital; A. H. Waring, of University College.

*Anatomy only.*—Edwin Folliot, William M. Coghlan and Bernard W. Holmes, of St. Bartholomew's Hospital; Percy H. Collingwood, James H. de Willers, George Candler and Frank E. Saunders, of St. Thomas's Hospital; Norman Macdonald, of St. Mary's Hospital; Thomas Herbert, of Middlesex Hospital; Arthur S. Turner, of Guy's Hospital; Alfred W. Hayes, of King's College.

*Physiology only.*—Gerald H. Goddard and Charles F. Wanhill, of University College; Frederick E. H. Keogh, of St. Mary's Hospital. Eleven candidates were referred in both subjects, three in Anatomy only and eleven in Physiology only.

Passed on the 9th inst. :—

*Anatomy and Physiology.*—Clement H. Hunter, Harry F. Spon and Ernest T. Shorland, of Guy's Hospital; Sideoy H. White, John E. Brash and Sidney Bridger, of University College; Frank Copeland, of Westminster Hospital; George W. Connor and Thos. H. Wells, of Middlesex Hospital; William W. Woolliscroft, of Charing-cross Hospital; Francis R. S. Cosens and George A. Leon, of London Hospital.

*Anatomy only.*—William P. Brooke and Montague M. Lowsley, of Charing-cross Hospital; Arthur B. R. Sworn, of University College.

*Physiology only.*—Richard Lumley Roberts, of Guy's Hospital; Thomas J. McCulla, of London Hospital and Mr. Cooke's School of Anatomy and Physiology; John Blackwood, of University College. Eighteen candidates were referred in both subjects, three in Anatomy only, and three in Physiology only.

Passed on the 11th inst. :—

*Anatomy and Physiology.*—Charles J. Kearney and William L. B. Davies, of Guy's Hospital; Richard D. Fisher, Edwin C. Smith and Thomas P. Littlejohn, of London Hospital; Jonas W. Leake, Robert W. S. Christmas, of Charing-cross Hospital; S. E. A. Zichy-Wornarski, of Melbourne University; Marcus B. Johnson, of Cambridge University and St. Mary's Hospital; Joseph Hayes, of McGill College, Montreal, and Mr. Cooke's School of Anatomy and Physiology; Francis E. Clay, of Westminster Hospital.

*Anatomy only.*—Duncan N. Macleannan, of Queen's University, Kingston, Canada, and Mr. Cooke's School of Anatomy and Physiology; Harold E. Dixon and Thomas W. Turner, of London Hospital; Lewis Savin, of Middlesex Hospital; Willie N. Barron, of St. Bartholomew's Hospital.

*Physiology only.*—Henry C. Lambert, of Queen's College, Birmingham, and Bristol School of Medicine; Alfred B. Wright, Alexander S. Grant, of London Hospital; John A. MacPhail, of McGill College, Montreal; David C. Kemp, of University College; Arthur E. Poake and Frederick Moreton, of Westminster Hospital; Alfred R. Hitchfield, of Guy's Hospital; A. A. Rogers, of St. Bartholomew's Hospital; William Ashford, of St. Thomas's Hospital.

Nine candidates were referred in both subjects, five in Anatomy only and four in Physiology only.

Passed on the 12th inst. :—

*Physiology only.*—Henry Harvey, William P. Thomas John J. Spears and Wm. F. Adams, of London Hospital; Montague H. C. Palmer, of Cambridge University and London Hospital; James R. Webb, of Melbourne University and London Hospital; Richard D. Stacy, William H. Pope, Martin A. Cooke, Percy W. G. Shelley, Burroughs M. Hughes and Alfred N. Wilde, of St. Bartholomew's Hospital; Walter J. O. Kay and Edward Haines, of St. Thomas's Hospital; William Gilbertson, of Cambridge University and St. Thomas's Hospital; Edward Fisk, William F. Byford, Stanley Rivers, Thomas S. Biggs and Percy E. Tresidder, of Guy's Hospital; Arthur T. Davey and John Gardiner, of Middlesex Hospital; Charles Mathews, of St. Mary's Hospital; Daniel Fogarty, of Ledwich School of Medicine, Dublin, and Mr. Cooke's School of Anatomy and Physiology. Eleven candidates were referred.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—The following gentleman, having passed the necessary examinations and having now attained the legal age of twenty-five years, was at the quarterly meeting of the Council on the 14th inst., admitted a Fellow of the College :—

Lee, Arnold William Warrington, M.B. Lond., L.R.C.P. Lond., of Owens College and Royal Infirmary, Manchester; diploma of Member dated Aug. 1st, 1890.

**SOCIETY OF APOTHECARIES OF LONDON.**—The following candidates have passed the recent Primary Examination in the respective subjects :—

*Chemistry, Materia Medica, Botany, and Pharmacy.*—E. M. Aikin, H. L. Billitt, E. C. Bond, T. Butcher, E. L. Colebrook, J. G. Horwood, C. E. Long, and E. M. Wells, of the Royal Free Hospital; E. G. Smith, Westminster Hospital; J. K. H. Smyth, St. Mary's Hospital; A. Wheeler, Edinburgh.

*Chemistry.*—J. Ash, Charing-cross Hospital; S. A. Clarke, Middlesex Hospital; M. Orange, Royal Free Hospital.

*Materia Medica, Botany, and Pharmacy.*—E. G. Adams, L. M. Blako,

E. Briggs, E. M. Gough, M. H. Harris, E. J. Macgowan, H. M. Maitland, M. Thorne, and C. S. Vines, of the Royal Free Hospital; C. Basan and S. Smith, Middlesex Hospital; C. Bayley, Charing-cross Hospital; A. P. B. Ellis, City School of Chemistry; F. T. Knott, Guy's Hospital; L. Macrae, King's College Hospital.

*Anatomy and Physiology.*—R. B. Allen and A. E. Mellersh, of St. Mary's Hospital; A. T. Anderson, Owens College, Manchester; E. Bentham, C. T. Green, Rukimabal, L. E. V. Saville, and A. M. Thornett, Royal Free Hospital; H. Clough, Yorkshire College, Leeds; R. Crawford, Belfast; W. J. Gething, Queen's College, Birmingham; W. A. Higgins, Cambridge; D. W. Jones, H. S. Oliver, and T. H. P. Peers, Charing-cross Hospital.

*Anatomy.*—J. Abrines and A. H. Wade, St. Bartholomew's Hospital; J. T. Brickwell, Guy's Hospital; A. H. Bygott, Queen's College, Birmingham; B. N. de Beauvais, Aberdeen; E. T. Fitzpatrick, Dublin; F. B. Hargreaves, Owens College; E. J. Macgowan, Royal Free Hospital; and A. Wheeler, Edinburgh.

*Physiology.*—C. Basan, Middlesex Hospital; W. E. V. Gould, Queen's College, Birmingham; T. E. Johnson and T. J. McCulla, London Hospital.

**KILSYTH, STIRLING.**—It is stated that Sir Archibald Edmonstone has given the town council of Kilsyth a right to supply water, which will be in addition to the present service, from a spring near Corry, as well as ground for a reservoir, free of expense.

**DEVONSHIRE HOSPITAL, BUXTON.**—The half-yearly report of this hospital is worthy of notice, for it shows a new departure worthy of imitation by provincial and other institutions of a similar kind. In addition to the medical report of the patients under treatment there is a statistical supplementary medical report, detailing the statistics of cases of rheumatism, rheumatoid arthritis and sciatica, which are collected from notes made since the commencement of the year. This report will give information of value as regards some of the most important points in the etiology of the diseases mentioned, but must be carried on for a much longer time before conclusions of value can be drawn. The house surgeon, Mr. E. Valentine Gibson, and the assistant house surgeon, Mr. H. R. Lloyd-Davies, are to be congratulated on this addition to the report, for without their voluntary exertions it would not have appeared.

**WEST LONDON MEDICO-CHIRURGICAL SOCIETY.**—The annual meeting was held on Friday, July 8th, Dr. Chas. Wells, President, in the chair. Dr. Wells delivered his valedictory address, in which he congratulated the Society upon the satisfactory progress of its tenth session. The papers generally have been upon subjects commanding attention and attracting interest, and the evenings devoted to the exhibition of clinical cases proved, as heretofore, very popular and were largely attended. He then referred to the excellence of the Cavendish Lecture by Sir Charles Cameron, on the Etiology of Typhoid Fever. The subject was admirably chosen, practical, full of original work, and the interesting experiments showing the diffusion of gases through porous soils were very striking, especially in relation to the fact of the greater frequency of typhoid fever upon gravel than upon the clay. This has a considerable bearing upon the salubrity of the locality of London. "Gravels," says Dr. E. A. Parkes in his "Practical Hygiene," "of any depth are always healthy except when they are much below the general surface and water rises through them," and many other authorities testify to the same result. It seems, therefore, that the old prejudice against living upon the clay is not well founded, certainly as regards the prophylaxis of enteric fever. Dr. Wells quoted from the reports of the medical officer of health of Hampstead, where the average death-rate from all zymotic diseases is 1.1 per 1000, in support of this theory. He also corroborated Sir Charles Cameron in pointing out the dangers of underground air entering our dwellings, and insisted upon the importance of covering the whole or the site of the house with cement or allied material. After referring with much regret to the loss by death of four members, Dr. Wells in conclusion again very heartily thanked the Society for the high honour conferred upon him by his election to the presidential chair and warmly acknowledged the generous support and assistance he had received from the Council and officers during his term of office. A vote of thanks to Dr. Wells was carried with acclamation. The following officers and Council were elected for the session 1892-1893 :—President: Mr. Swinford Edwards. Vice-Presidents: Mr. R. W. Lloyd, Dr. J. B. Ball, Mr. L. Mark and Dr. Symons Eccles. Council: Drs. Abraham, Banning, Batten, C. W. Chapman, Clippingdale, Masters, Schacht, Messrs. Benham, Bruce Clarke, Percy Dunn, R. Lake and Mansbridge. Treasurer: Mr. Gunton Alderton. Secretaries: Mr. J. Herbert Menzies and Dr. A. Clemow. Librarian: Dr. Schacht.

THE Queen has been pleased to give directions for the appointment of Francis Volcy Pougnet, Esq. M.D., to be a member of the Council of Government of the Colony of Mauritius.

**KIDDERMINSTER INFIRMARY.**—The committee of this institution has accepted an offer from Mr. Howard C. Jobson of Summerhill to give a donation of £250 to endow a bed in the infirmary in memory of the late Mr. W. C. Audry.

**DISEASED MEAT AT ILKESTON.**—A Nottingham butcher has been prosecuted by the town authorities, at the Ilkeston Petty Sessions, for exposing for sale forty-seven pieces of meat unfit for human food, and fined 3s. for each piece and costs—total £8 7s. 6d.

**LONDON SCHOOL OF DENTAL SURGERY.**—On Wednesday, at the Royal Institute Galleries, Piccadilly, Professor St. George Mivart, F.R.S., distributed the prizes won by the successful students at this school, which is in connexion with the Dental Hospital. After the distribution the professor referred to the growth of the school as shown by the fact that, whereas in 1875 the students numbered but ten, at the present time they had increased to one hundred. The principal prize winners were Mr. G. Northcroft, who gained the Saunders's Scholarship, and Mr. H. J. Stevens, who won the prize given by Messrs. Ash and Sons for the best essay. The first prizes in class subjects were awarded to the following: Mr. H. J. Stevens, in Dental Metallurgy and Dental Surgery; Mr. E. H. Harwood, in Dental Mechanics; Mr. T. H. Clarence, in Operating; and Mr. H. W. Trewby, in Dental Anatomy.

**POOR-LAW MEDICAL OFFICERS' ASSOCIATION.**—At a meeting of the Council held at their rooms, 3, Bolt-court, Fleet-street, on July 12th, 1892, the case of the late Mr. C. A. Walters of Cheltenham, who died on the 8th inst., was further considered, and the following resolutions were unanimously passed: "That the suspension of Mr. Walters by the guardians of Cheltenham for declining to attend the child of Drusilla Cook without a medical order, which was no dereliction of duty whatever, was not only uncalled for but also seriously unjust. That the 'severe censure' passed on Mr. Walters by the Local Government Board for no serious fault, and which appears to have accelerated his death, was unwarranted and even cruel, and especially to a medical officer who had held his appointment for thirty-eight years. That in the opinion of this Council the guardians of the Cheltenham Union were themselves guilty of a grave error in having sanctioned any form of relief being given to Drusilla Cook, who had received over £100 since the death of her husband, and this within the past twelve months, and who had £30 deposited in the savings bank at the time her weekly allowance was granted by the board. That a copy of these resolutions be sent to the guardians of the Cheltenham Union, to the medical journals, and to the Cheltenham local press."

**DENTISTRY AND WORKHOUSE CHILDREN.**—At the weekly meeting of the Strand Board of Guardians on Tuesday evening an important discussion arose on a communication from the Local Government Board approving of a resolution passed by the guardians of the Strand Union at a recent meeting for the appointment of a qualified professional dentist to attend the children of the schools at Edmonton, the salary, however, not to be made a charge on the common poor fund. The chairman remarked that this was the first appointment of the kind made by any metropolitan or provincial board of guardians, and he thought the Strand Union deserved every credit for initiating such a necessary and beneficial advance in the hygienic treatment of the poor children in their workhouses and schools; but he could not understand the objection of the Local Government Board to charging the dentist's stipend on the common poor fund. Mr. Walker was glad to note that the course taken by the guardians had met with the approval of their regular medical and surgical staff, and there was no narrow-minded professional jealousy or animus shown at the proposed creation of a new semi-medical office. There was a large number of children in the schools of the Union, and for their present physical comforts and future health and prospects in life it was essential their teeth should be well looked after. Several other guardians concurred in the importance of the subject, and in the result the board agreed to carry out the instructions of the Whitehall authorities and to elect a duly qualified dentist at the next meeting.

**A HOSPITAL FOR STOURBRIDGE & C.**—Mr. John Corbett, late M.P. for Mid-Worcester, has made a further donation of £500 for furnishing and equipping the hospital he is founding for the Stourbridge and Brierley-hill district.

**OPEN SPACES.**—The Local Government Board has sanctioned the borrowing of £41,250 by the Corporation of Dewsbury, for the purchase and laying-out of a public park and street improvements. The estimated cost of the park is £33,250.

**PHARMACEUTICAL SOCIETY OF IRELAND.**—The following candidates have obtained the licence of the Society: R. S. Moore, T. J. Walsh, G. F. Walsh, T. Whelehan, G. F. Stevenson, M. L. Tierney, R. J. Cahir, W. J. Hartnett, C. O'Connor, J. H. Graham, H. A. Kelso, and J. W. Peatt.

**UNIVERSITY COLLEGE HOSPITAL.**—In consequence of the necessity for carrying out extensive repairs, painting, &c., it has been decided to close University College Hospital, with the exception of the maternity department, for six weeks from the 20th inst. The committee appeal for funds to enable them to meet the heavy expenditure.

**PRESENTATION TO DR. J. H. BRIDGES.**—A massive silver bowl was presented to Dr. J. H. Bridges on Monday, July 4th, in the library of the British Medical Association, 429, Strand, W.C. The bowl had been subscribed for by the medical officers of the metropolitan fever hospitals, district asylums, poor-law schools and workhouses. The chairman, Mr. J. Adams Clarke (Medical Officer of the St. Pancras Schools at Leavesden), in making the presentation, paid a graceful tribute to Dr. Bridges' high qualifications, ability, and courtesy, and acknowledged the help invariably shown by him to those with whom he came into official contact. Dr. MacCombie (of the South-Eastern Hospital) expressed the regard felt for Dr. Bridges by the medical superintendents of the metropolitan fever hospitals, and Dr. A. H. Robinson (of Mile End Infirmary) spoke on behalf of the infirmaries and schools. Dr. Bridges, after expressing his gratification at the handsome present he had just received, spoke of the numerous difficulties encountered when he assumed the duties of an Inspector of the Local Government Board twenty-three years ago. Dr. Bridges, in taking leave of those present, hoped that he should not lose touch of those medical officers with whom he had been in official contact for so many years. The proceedings were brought to a termination by formal votes of thanks to the chairman and to the secretaries of the movement, Drs. Littelljohn and Sydney Stephenson.

## Appointments.

*Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

**ALCOCK, REGINALD**, has been appointed Assistant House Surgeon to the North Staffordshire Infirmary and Eye Hospital, vice J. F. Crombie.

**ANDREW, A., L.R.C.P., L.M. Irel.**, has been appointed Medical Officer for the Glossop Sanitary District of the Glossop Union.

**BENSON, ANNETTE M., M.B., B.Sc. Lond.**, has been appointed Resident Medical Officer to the Victoria Hospital for Children, Hull.

**CARLING, W., B.A., M.B., B.C. Cantab.**, has been appointed Assistant House Surgeon to Guy's Hospital.

**CARROLL, J., M.B., C.M. Glasg., D.P.H. Camb.**, has been reappointed Medical Officer of Health for Ilkeston.

**CROMBIE, J. FRANK, M.B., C.M. Edin.**, has been appointed House Surgeon to Great Yarmouth Hospital.

**EATON, J., M.R.C.S.**, has been appointed Medical Officer for the Splittlegate Sanitary District and Workhouse, and Public Vaccinator to the Grantham Union, vice Bailoy, resigned.

**EVANS, A. ERNEST, M.B., C.M. Glasg.**, has been appointed House Physician to the City of London Chest Hospital.

**FAGAN, JOSEPH P., L.R.C.S., L.R.C.P. Irel., L.M.**, has been appointed Assistant Surgeon to the South Dispensary, Liverpool, vice Dr. J. G. Moyle, resigned.

**FARQUHARSON, WM. F., M.B. Edin.**, has been appointed Assistant Medical Superintendent to the Counties Asylum, Carlisle, vice D. M. M. Ross, M.B.

**FOLKER, HENRY HERBERT, M.R.C.S., L.R.C.P. Lond.**, has been appointed Honorary Assistant Ophthalmic Surgeon to the North Staffordshire Infirmary and Eye Hospital.

**FULLER, JOHN B., M.R.C.S., L.R.C.P. Lond.**, has been appointed Senior Resident Medical Officer of the Birmingham Children's Hospital.

**GARRETT, JOHN HY., M.D., L.S.Sc. Durh., D.P.H. Camb.**, has been appointed Medical Officer of Health for the Borough of Cheltenham, vice Dr. Sampson Roch, resigned.

GODSON, A. H., B.A., M.B., B.C. Cantab., has been appointed Assistant House Surgeon to Guy's Hospital.

GREEN, A., M.B. Lond., L.R.C.P., M.R.C.S., has been appointed Surgeon of the Chesterfield and North-East Derbyshire Hospital.

HAWORTH, S. R., M.D., C.M. Irel., has been appointed House Surgeon to the Bridgnorth Infirmary, vice Craig, resigned.

HOUGHTON, MURTAUGH J., L.S.A., has been appointed Assistant to the House Surgeon and Physician at the Wolverhampton General Hospital, vice R. S. Hogarth.

JOHNSON, T. C., M.B., C.M. Edin., has been appointed Medical Officer for the Middleham Western Sanitary District of the Leyburn Union.

MURRAY, B. W., F.R.C.S. Eng., has been appointed Surgeon to the Liverpool Infirmary for Children, vice R. N. Pughe, resigned.

PEARSON, JOSEPH, M.B., C.M. Aberd., has been appointed Honorary Assistant Medical Officer to the Children's Hospital, Sheffield, vice C. H. Willey, M.D.

RAINY, HARRY, M.B., C.M. Edin., has been appointed Resident Medical Officer to the Chalmers Hospital, Edinburgh, vice Mackenzie.

RICHARDSON, G. G., L.R.C.P., L.R.C.S. Irel., has been appointed Junior Resident Medical Officer of the Birmingham Children's Hospital.

ROBERTS, J. LLOYD, M.B., C.M. Edin., D.P.H. Eng., has been reappointed Medical Officer of Health for the Abergele and Ponsarn Urban Sanitary District of the St. Asaph Union.

ROSS, DONALD M. M., M.B., C.M. Edin., Senior Assistant Medical Officer, Cumberland and Westmoreland Asylum, Carlisle, has been appointed District Medical Officer in the Government Medical Service, Jamaica.

SLEVIN, P. J., L.R.C.P., L.R.C.S. Irel., has been appointed Medical Officer for the West Drayton Sanitary District of the Uxbridge Union.

TURNBULL, W. H., M.B., B.S., B.Hy. Durh., has been appointed Medical Officer of Health for the Borough of South Shields, vice Dr. T. E. Hill.

WETHERELL, J. A., M.D., C.M. Edin., has been appointed Resident Medical Officer and Government Resident at Wyndham, Western Australia.

WILEY, C. H., M.D., has been appointed Honorary Medical Officer to the Children's Hospital, Sheffield.

YOUNG, F. C., B.A., M.B., B.C. Cantab., has been appointed Assistant House Physician to Guy's Hospital.

## Vacancies.

For further information regarding each vacancy reference should be made to the advertisement.

ANCOATS HOSPITAL, Manchester.—Senior House Surgeon. Salary £80, with board and washing.

BOROUGH HOSPITAL, Birkenhead.—Junior House Surgeon. Salary £60 per annum, with board and lodging, but no wine, spirits, or beer. A further sum of from £20 to £25 per annum is usually obtained in fees.

BRADFORD CHILDREN'S HOSPITAL.—House Surgeon. Salary £70, with board, residence and washing.

BURY DISPENSARY HOSPITAL, Bury, Lancashire.—Senior House Surgeon. Salary £100 per annum, with board, residence, and attendance.

ECCLES AND PATRICROFT HOSPITAL.—House Surgeon. Salary commencing at £60 per annum, with board and residence in hospital. (Apply to the Honorary Treasurer, 11, Quay-street, Manchester.)

EVELINA HOSPITAL FOR SICK CHILDREN, South-wark-bridge-road, S.E.—Junior Resident Medical Officer. Salary £60.

FULHAM UNION.—Assistant Medical Superintendent of the Infirmary. Salary £100 per annum, increasing £10 yearly to a maximum of £130, with board, furnished apartments, attendance and washing.

GREAT NORTHERN CENTRAL HOSPITAL, Holloway, N.—House Surgeon. Salary £60 per annum, with board and lodging in the hospital.

HORTON INFIRMARY, Banbury.—House Surgeon and Dispenser. Salary £60 per annum, with board and lodging.

JOINT COUNTIES ASYLUM, Abergavenny.—Junior Assistant Medical Officer. Salary (a progressive one) commences at £100 a year, with apartments, board and attendance.

LINCOLN ODDFELLOWS' MEDICAL INSTITUTE.—A qualified Assistant. Salary £120 a year (out-door). (Apply to the Secretary, 12, North Parade, Lincoln.)

LIVERPOOL NORTHERN HOSPITAL.—Assistant House Surgeon. Salary £70 per annum, with residence and maintenance in the house.

LOUGHBOROUGH FRIENDLY SOCIETIES' MEDICAL AID ASSOCIATION.—Junior Medical Officer. Commencing salary £160 per annum.

MCGILL UNIVERSITY, Montreal, Canada.—Professorship of Pathology for the Faculties of Medicine and Comparative Medicine for one year. Salary for provisional appointment for one year £400 sterling. (Apply to the Dean, Montreal, Canada.)

METROPOLITAN ASYLUMS BOARD, Norfolk-street, Strand, W.C.—Clinical Assistant at the Darenth Schools and Pavilions for Imbeciles, near Dartford, Kent. Board, lodging and washing provided.

NOTTINGHAM BOROUGH ASYLUM.—Resident Clinical Assistant for six months. Board and residence provided.

QUEEN'S HOSPITAL, Birmingham.—Physician for Out-patients and Pathologist to the Institution for three years. Annual honorarium £75.

ROYAL HOSPITAL FOR CHILDREN AND WOMEN, Waterloo-bridge-road, S.E.—Obstetric Physician.

ROYAL PORTSMOUTH, PORTSEA, AND GOSPORT HOSPITAL, Portsea.—Assistant House Surgeon for six months. Board, residence and washing, and an honorarium of £15 15s. at expiration of term of office.

ROYAL SEA-BATHING INFIRMARY FOR SCROFULA, Margate.—Resident Surgeon. Salary £100 per annum, with board and residence. (Apply to the Secretary, Offices, 30, Charing-cross, S.W.)

SHEFFIELD PUBLIC HOSPITAL AND DISPENSARY.—Senior Assistant House Surgeon. Salary £65 per annum, with board, lodging and washing.

ST. LUKE'S HOSPITAL.—Resident Clinical Assistant for six months, with board and residence.

ST. MARYLEBONE GENERAL DISPENSARY, 77, Wolbeck-street, W.—Resident Medical Officer. Salary £105 per annum, with furnished apartments, attendance, coal and gas.

VICTORIA INFIRMARY OF GLASGOW.—Superintendent and Resident Medical Officer. Commencing salary £150 per annum, with apartments and board.

WEST KENT GENERAL HOSPITAL, Maidstone.—House Surgeon. Salary £150 per annum, with furnished apartments, coals, gas and attendance in the hospital.

WONFORD HOUSE HOSPITAL FOR THE INSANE, near Exeter.—Assistant Medical Officer. Salary £150 per annum, with board, furnished apartments, and washing.

WORCESTER AMALGAMATED FRIENDLY SOCIETIES' MEDICAL ASSOCIATION, Worcester.—Assistant Medical Officer. Salary (without residence) £140 per annum, with part of Midwifery fees; also £20 per year for cab hire.

## Births, Marriages, and Deaths.

### BIRTHS.

DUNLOP.—On June 30th, the wife of Shuldham Dunlop, M.D., Holywood, county Down, of a son.

FRAZER.—On July 9th, at Bellgrove-terrace, Newcastle-on-Tyne, the wife of Surgeon-Major P. T. Frazer, Army Medical Staff (Retired), of a daughter.

HAIRISINE.—On July 4th, at Roose House, Upper Tooting, S.W., the wife of Hudson Hairisine, L.R.C.P., of a son.

LANGTON.—On July 12th, at Marlborough-place, Brighton, the wife of Herbert Langton, M.R.C.S., of a daughter.

MARTIN.—On July 12th, at Arnheim, Blackburn, the wife of John M. H. Martin, M.D. (Vict.), F.R.C.S. Eng., J.P., of a son.

MORRIS.—On July 12th, at Windhill, Bishop's Stortford, the wife of John Edward Morris, M.D., of a daughter.

SELBY.—On July 11th, at Teynham, Kent, the wife of Prideaux George Selby, L.R.C.P. Lond., M.R.C.S., of a daughter.

WALE.—On July 6th, at High-street, Croydon, the wife of George Wale, L.R.C.P. Lond., D.P.H. Camb., M.R.C.S., of a son.

### MARRIAGES.

COLE-BAKER—LYSTER.—On July 13th, at St. Peter's Church, Dublin, G. Cole-Baker, M.B., Assistant Master, Coombe Hospital, 28, Lower Baggot-street, to Florence, widow of the late Philip T. Lyster, R.M.

HARDEN—LEVY.—On July 6th, at St. Mark's, Hamilton-terrace, N.W., Edward Henry Thornborough Harden, M.R.C.S., L.R.C.P. Lond., eldest son of the late Henry Harden, M.R.C.S., of St. Mawes, Cornwall, to Emily Agnes, youngest daughter of the late Albert Levy, of Hall-road, N.W.

LUKE—RUSSELL.—On July 12th, at The Lodge, Elle, N.B., by the Rev. P. Hay Hunter, Minister of Yester, assisted by the Rev. R. H. Dunlop, Minister of Elle, and the Rev. Duncan MacGregor, Minister of the Free Church, Elle, James Luke, M.B., C.M., to Elizabeth, daughter of the late George Russell, J.P., of The Lodge, Elle.

PINHORN—BRYANT.—On July 7th, at Christchurch, Marylebone, Richard Pinhorn, M.R.C.S., L.R.C.P. Lond., L.S.A., of Cambridge-terrace, Dover, to Susan Catherine Victoire, widow of the late Lieut.-Colonel G. F. Bryant, Indian Army (2nd Belooch Regt.).

SCOTT—LAMB.—On July 6th, at St. Stephen's Church, C.-on-M., Manchester, Benjamin Scott, M.B., C.M., of Ardwick-green, Manchester, to Alice Mary (Mollie), second daughter of the late Alderman Joseph Lamb, J.P.

SCOTT—MOLONY.—On July 5th, at Christ Church, Crookham, Hants, Horatio Scott, M.D., Surgeon-Major Retired, of Basingbourne, Fleet, Hants, son of the late Rev. J. L. M. Scott, Rector of Portferry, to Eleanor Florence, second daughter of the late Frederick Beresford Molony, Madras Civil Service.

WIGAN—HOPKINS.—On July 6th, at Easton Church, near Winchester, Charles Arthur Wigan, M.D., of Portishead, Somerset, to Emily, daughter of Major Powell Hopkins, late 16th Regiment, and granddaughter of the late General Sir Philip Baimbrige, K.C.B.

### DEATHS.

BALKWILL.—On July 11th, very suddenly, at 14, Old Cavendish-street, Cavendish-square, London, William Edward Balkwill, aged 43.

BURCHELL.—On July 5th, at Delamers, Bradwell-on-Sea, Southminster, Essex, Peter Lodwick Burchell, M.B. Lond., F.R.C.S. Eng., aged 74 years and 10 months.

DOUZY.—On July 12th, at Moulsoford, J. Harrington Douzy, M.R.C.S., L.S.A., Superintendent of the Berks County Asylum, late of Netherhampton, Salisbury, aged 34.

MURPHY.—On June 24th, at Cork, Surgeon-Major F. H. S. Murphy, Army Medical Staff, aged 37.

RUTHERFORD.—On July 2nd, at Pulborough, Sussex, Samuel Rutherford, M.D., M.R.C.S., L.S.A., aged 64.

SYLVESTER.—On July 10th, at Dry Hill Park, Tunbridge, Harold Augustus Sylvester, M.R.C.S., fifth son of S. A. Sylvester, in his 28th year.

WALLACE.—On July 5th, at Grange Mount, Cloughton, Cheshire, Quintin Macadam Wallace, M.D., aged 30.

WALTERS.—On July 8th, at Wharfedale House, Cheltenham, Charles Astley Walters, M.R.C.S., aged 67.

WEISS.—On July 4th, Hubert Foveaux Weiss, F.R.C.S. Eng., of Granville-gardens, Ramsgate, and Piccadilly, W., aged 87.

N.B.—A fee of 6s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

## METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

THE LANCET Office, July 14th, 1892.

## Notes, Short Comments &amp; Answers to Correspondents.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*All communications relating to the editorial business of the journal must be addressed "To the Editors."*

*Lectures, original articles, and reports should be written on one side only of the paper.*

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."*

*We cannot undertake to return MSS. not used.*

## THE DISCOVERY OF THE CIRCULATION OF THE BLOOD.

NO discovery has been so gradual as that of the circulation of the blood, and an adequate history of the steps by which the ground was prepared for Harvey's immortal induction has yet to be written. We have had monographs from time to time setting forth the claims of pioneers like the Spaniard Serveto and the Italian Cesalpino to having, in part if not in whole, anticipated the English physiologist, while enthusiastic "vindicators" like Dr. Archibald Pitcairne have contended that for those who can "read between the lines" the discovery was as good as made by Hippocrates himself. But, we repeat, a competent historian of the most momentous finding in physiology has yet to appear. Early in the third century after Christ (a scholarly correspondent reminds us), probably in the reign of the Emperor Caracalla, were published the "Recognitions of Clement," in the eighth book of which there is certainly a remarkable adumbration of Harvey's discovery: "What shall I say of the substance of the blood which, proceeding as a river from a fountain and first borne along in one channel and then spreading through innumerable veins, irrigates the whole territory of the human body with vital streams, being supplied by the agency of the liver, which has its seat in the right side for effecting the digestion of food and turning it into blood?" The passage is of deep interest, and in that history which we have already desiderated must find its place as an important link in the inductive chain which it was reserved for Harvey to complete and to connect with universal truth.

*Anxious.*—It is only safe to employ a qualified assistant under the immediate supervision of the principal and living in the same house.

*Mr. J. W. Cook.*—We do not recommend practitioners.

## PSEUDO-CYESIS.

To the Editors of THE LANCET.

SIRS,—You may think the following case of spurious pregnancy of sufficient interest for publication.

A lady engaged me to attend her in her confinement. She stated that she was eight months pregnant. Inquiring her age, I discovered she was fifty-two years old, which surprised me, and I obtained the following history. Until to eight months before she had been perfectly regular and showed no signs of change of life. She was a widow with two children, the youngest being of age. She had incurred the risk of impregnation

eight months previously with a man who promised her marriage, which promise he has not fulfilled. Morning sickness almost immediately set in and lasted for seven weeks. The breasts became painful and she "quickened" at the beginning of the sixth month, since when, she said, "the kicks have often made me feel faint." She increased greatly in size. I did not then examine her. Five weeks later I was sent for, as she was said to be in labour. The pains were very strong and frequent on my arrival. Palpation failed to reveal the presence of a child, though the abdomen was very large; breasts turgid and secreting milk freely. While examining the abdomen I saw a distinct impulse, and on placing my hand over the point felt the rectus muscle violently contract. It was very like the kick of a child. Vaginal mucous membrane normal in colour; cervix ulcerated and congested. The sound passed into the womb registered 8½ in. The os slightly patulous. Temperature of patient 100°; pulse 100 and irregular. I assured the patient and her friends that she was not pregnant, but I think they would like to have assured me I was not sane. However, I insisted upon it, and very shortly the pain ceased. Next morning the breasts had ceased to secrete milk, the abdomen was decidedly less in size and there had been no pain. I ordered the patient up and to go out (she had not been out for nine months, fearing recognition of her state), which she did, and a few days after had a regular menstrual flow and is now in her normal healthy condition. The patient after connexion had been much worried, fearing impregnation, and had been unable to sleep, and the symptoms very soon showed themselves and followed the regular order. She had disclosed her condition to her family, causing much grief, and in all good faith had prepared everything for her confinement and lying-in.

I am, Sirs, yours faithfully,

July, 1892.

G. HAY REYNOLDS, M.B.

## MEDICAL AID ASSOCIATIONS.

To the Editors of THE LANCET.

SIRS,—In reply to the question asked by "A. H. T. D.," may I point out that there is nothing to prevent any association from making a contract with a member of the legal profession in order to obtain advice at a low rate, and that if the Incorporated Law Society or the General Medical Council try to interfere in those matters they will have to be dealt with by a still more powerful body, the House of Commons, the vast majority of whose members are dependent for their seats on the votes of men who are either members of friendly societies or who sympathise with those who are. Moreover, were the whole population of these islands to secure advice and medicine by paying 1d. per week the income of a medical man would be about £300 a year, and if we consider that the larger incomes made in our profession are drawn from a comparatively small wealthy class who will not join friendly societies, we can see that no increase of such societies can greatly reduce the incomes of medical men. I have been in the employment of a practitioner who paid me barely 5 per cent. of the income he received from my work, whereas now, in the employment of a friendly society, I receive about 50 per cent. of the payments of members and all the midwifery fees. What is it to me who gets the surplus, and why should I fancy I have any claim on it? There are many other reasons which make me prefer my present position to that of an assistant; there is no possibility of differing on a professional matter from my employer—a difference which, whether he proves to be right or wrong, results unpleasantly for an assistant; I hold a permanency during good behaviour, and cannot be dismissed to make way for a partner or for the principal's son (newly qualified); my employers increase my salary according to promise and do not allege that "business is bad," for the plain reason that they have no interest in doing otherwise; I receive far more respect from my patients than I should receive in a surgery, where the patient, having his fee ready and knowing that other surgeries are open to him, regards the doctor as he does the publican. I very seldom see my employers, and am not interfered with by them in the discharge of my duties. All these reasons lead me to think that assistants are justified in looking on even a junior position in connexion with a medical association as a prize, and that they do so is shown by the keen competition for such appointments. As to the fact that the parish nurses attend our cases, I may point out that instances are not rare in which even patients who pay large fees to their medical attendant seek the services of these women. In conclusion I may say that I have heard of no instance in which a doctor was refused an appointment because of his having been connected with a Medical Aid Society.

I am, Sirs, yours faithfully,

July, 1892.

VERAX.

## INCREASE OF MEDICAL OFFICERS' SALARY.

A GENERAL MEETING of the Glamorgan County Council Asylum Committee was held recently to consider applications on behalf of the medical staff for increase of salary on account of increased duties. It was recommended that the medical superintendent, Dr. Pringle, should have his salary increased from £800 to £1000; Dr. Stewart, second in charge, to have an increase from £200 to £250; Dr. Findlay to be raised from £150 to £200; and another medical officer at Angeltown to be increased from £120 to £150.

*Suffolk.*—The question is hardly one for us to decide, but in the absence of other evidence it would appear as if the clause quoted stated the precedence of the parties.

## THE "STABILIMENTO BALNEARE" AT NOCERA.

PROFESSOR MURRI of Bologna, than whom there are few better qualified to speak authoritatively on therapeutics, has put on record his high opinion of the virtues of the waters of Nocera, particularly in gouty affections in which stomach, liver, kidneys and heart are involved. The source that yields the so-called *Acqua Bianca* has proved of signal efficacy in the uric acid diathesis, and the air of the locality is such as to cooperate effectively in promoting a return to the healthy state. Like other centres of mineral-water supply, Nocera after centuries of popularity fell into disrepute, sharing, indeed, the general decadence that befell Italy after the Renaissance. It was still resorted to in 1714, the year in which a medal was struck to commemorate the building of the Palazzo Nuovo by Pope Clement XI., who highly appreciated its healing resources; but shortly after that date it had almost ceased to attract visitors, in spite of its noble position, its excellent air and the undoubted virtues of its *Acqua Bianca*. Quite recently, however, it has, like many other Italian institutions, undergone a resurrection, and few "stabilimenti balneari" in the peninsula have done more to merit a return to popular favour. In summer its temperature ranges from 16° to 22° C.; it is sheltered from the hot winds of the south; its air is dry, pure and restorative, not too stimulating for the nervous system and very grateful to delicate chests. It has, moreover, warm alkaline baths for disorders of the skin and for rheumatic and gouty subjects, and its hydrotherapeutic staff consists of able physicians provided with every resource for the inhalation of compressed or rarified air, for the practice of Faradisation and other electrical treatment, culminating in "bagni elettrici" proscribed and administered by well-qualified consultants and attendants. Professor Murri's attestation to the value of the "stabilimento" is confirmed by the written opinions of Professor Castiglioni and Dr. Barduzzi, two eminently sound authorities, who have had personal experience of its efficacy. Add to this the lovely landscape of Umbria, recalling so many *chefs-d'œuvre* of Perugia and his pupil Raphael, and Nocera would seem to be a health resort inferior to none in Italy and to few in Austro-Hungary, Switzerland, Germany or France. Hotel accommodation, usually defective in Italy, has of late years been much improved throughout the peninsula, and that of Nocera, previously sharing in the general roughness of Italian houses, now affords a favourable specimen of the more comfortable appointments demanded by modern civilisation. The season is now at its height, but the early summer and the late autumn have much to recommend them, especially to the visitor from northern latitudes.

*Lex.*—Much depends on the distance between the towns A and B and the possibility of C being able to take personal interest in and exercise supervision over affairs in town A. The mode of procedure is not ordinary, but we are not prepared to say it is wrong.

## THE OPIUM HABIT.

To the Editors of THE LANCET.

SIRS,—In reply to the letter of "Opium" I beg to inform him that there is no limit to the quantity of opium or tincture of opium that a druggist may sell to a customer. A few months since I discovered that a druggist had for many years supplied one of my patients with thirty or forty ounces at a time of tincture of opium. This patient had contracted the opium habit, but although I suspected that small quantities were taken I was astonished to find that it had been possible to procure it in the quantity I have mentioned. I have been informed on good authority that the Sale of Poisons Act does not in any way prohibit the sale of laudanum in any quantity and without any inquiry as to the name of the purchaser or the purpose for which it is required. This reveals a most lamentable state of things, and shows the necessity for an amendment of the law. The Association for Preventing the Sale of Opium to the Chinese should investigate the subject of the facilities for obtaining opium without let or hindrance in England.

I am, Sirs, yours obediently,  
SANITAS.

July 11th, 1892.

*Medical Superintendent.*—Misrepresentation and exaggeration are inexcusable in a lady allowed to visit hospital patients. But any honest criticism directed in the first instance to the authorities of the hospital should be welcomed.

*Correspondent.*—He should be willing to do so if required.

## LIFE INSURANCE.

To the Editors of THE LANCET.

SIRS,—The vital importance of life insurance for the medical profession must be my excuse for asking you to allow me to call your readers' attention to the Pioneer Life Office of Liverpool, which seems to be very little known in London. The advantages offered are so great, the premiums so small and the system so easily grasped that I would advise all intending insurers to thoroughly examine it.

I am, Sirs, yours faithfully,  
M.D.

June 20th, 1892.

## CHOLERA REGULATIONS.

The following General Order has been issued by the Local Government Board to portsanitary authorities, urban and rural sanitary authorities, medical officers of health, officers of customs, masters of ships &c.:

"Whereas cases of an infectious disease alleged to be cholera now exist in certain parts of France and it is expedient that regulations should be made with reference to ships having on board bales of rags from that country, now therefore we, the Local Government Board, do by this our Order, and in exercise of the power conferred on us by Section 180 of the Public Health Act, 1875, by the Public Health Act, 1880, by Section 118 of the Public Health (London) Act, 1891, and every other power enabling us in this behalf, make the following regulations, and declare that they shall be enforced and executed by the authority or authorities specified: 1. From and after July 12th, 1892, and until we shall by order otherwise direct, no rags from France shall be delivered overside, except for the purpose of export, nor landed in any port or place in England or Wales.—2. If any rags shall be delivered overside or landed in contravention of this order, they shall, unless forthwith exported, be destroyed by the person having control over the same, with such precautions as may be directed by the medical officer of health of the sanitary authority within whose jurisdiction or district the same may be found.—3. All masters of ships consignees and other persons having control over any rags prohibited under this order from being delivered overside, except for the purpose of export, or landed, are required to obey these regulations.—4. All officers of customs are empowered to prevent the delivery overside or landing of rags in contravention of this order.—5. It shall be the duty of the sanitary authority to take proceedings against masters of ships, consignees or other persons having control over any rags, who shall wilfully neglect or refuse to obey or carry out, or shall obstruct the execution of any of these regulations." [The Public Health Act, 1875, provides by Section 180 that any person wilfully neglecting, or refusing to obey or carry out, or obstructing the execution of any regulation made under that Section shall be liable to a penalty not exceeding £50.]

## CLAIM TO EMERGENCY CASES.

*One Anxious to Know.*—We think Dr. A. has no claim to the case in question. Claims arise either from previous attendance on patients, or from a sudden call in an emergency. But it cannot be maintained that a message in an emergent case to the practitioner whose door comes first in the messenger's way gives any claim to the case.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Messrs. Allen and Hanburys, London; Mr. R. Bingham Adams, Southsea; Mr. E. Brown, Birmingham; Mr. J. F. Bullar, Southampton; Dr. J. St. Clair-Boyd, Belfast; Dr. R. W. Bateman, Newmarket; Messrs. A. and C. Black, Edinburgh; Mr. Baron, Manchester; Messrs. Burgoyne and Co., London; Dr. Bobardt, Newbury; Dr. H. J. Buck, Clapton Common; Mr. J. B. Browne, London; Messrs. Baillière, Tindall, and Cox, London; Mr. Philip Boobyer, Nottingham; Messrs. Black, London; Mr. Birchall, Liverpool; Dr. Canney, London; Surgeon-Lieutenant-Colonel A. Crombie, Calcutta; Messrs. Chapman and Farrington, London; Mr. Cooke, London; Dr. Coghill, Birmingham; Dr. W. Dale, London; Mr. Davids, Banbury; Mr. J. H. Dewhurst, Tunbridge Wells; Messrs. W. and W. Davies, Brighton; Mr. Havelock Ellis, London; Mr. Fardon, Liverpool; Mr. J. Foare, Liverpool; Mr. Gravatt, London; Messrs. Chas. Griffin and Co., London; Mr. T. Campbell Grey, Swansea; Mr. Heywood, Manchester; Mr. Harding, Loughborough; Messrs. Humphreys, London; Mr. J. W. ## Medical Diary for the ensuing Week.

### Monday, July 18.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M., and on Tuesday, Wednesday, Friday, and Saturday at the same hour.  
 ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations daily at 10 A.M.  
 ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M. and each day at the same hour.  
 CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2.30 P.M.  
 HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.  
 METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.  
 ROYAL ORTHOPEDIC HOSPITAL.—Operations, 2 P.M.  
 CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and each day in the week at the same hour.  
 UNIVERSITY COLLEGE HOSPITAL.—Ear and Throat Department, 9 A.M.; Thursday, 9 A.M.

### Tuesday, July 19.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.; Fridays and Saturdays at the same hour.  
 GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.  
 ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.  
 ST. MARK'S HOSPITAL.—Operations, 2 P.M.  
 CANCER HOSPITAL, BROMPTON.—Operations, 2 P.M.; Saturday, 2 P.M.  
 WESTMINSTER HOSPITAL.—Operations, 2 P.M.  
 WEST LONDON HOSPITAL.—Operations, 2.30 P.M.  
 ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M. Throat Department, Tuesdays and Fridays, 1.30 P.M. Electro-therapeutics, same day, 2 P.M.

### Wednesday, July 20.

NATIONAL ORTHOPEDIC HOSPITAL.—Operations, 10 A.M.  
 MIDDLESEX HOSPITAL.—Operations, 1.30 P.M.; Saturdays, 2 P.M. Obstetrical Operations, Thursdays, 2 P.M.  
 CHARING-CROSS HOSPITAL.—Operations, 3 P.M., and on Thursday and Friday at the same hour.  
 ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.  
 LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.  
 ST. PETER'S HOSPITAL, COVENT-GARDEN.—Operations, 2 P.M.  
 SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.  
 GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.  
 UNIVERSITY COLLEGE HOSPITAL.—Operations, 1.30 P.M.; Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.  
 ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.  
 CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9.30 A.M. Surgical Visits on Wednesday and Saturday at 9.15 A.M.

### Thursday, July 21.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Surgical Consultations, Wednesday, 1.30 P.M. Ophthalmic Operations, Friday, 1.30 P.M.  
 UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Ear and Throat Department, 9 A.M.

### Friday, July 22.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

### Saturday, July 23.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; and Skin Department, 9.15 A.M.

## SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year ..... £1 12 6 | Six Months ..... £0 16 3

TO THE CONTINENT, COLONIES, UNITED STATES, INDIA, CHINA, AND ALL PLACES

ABROAD ..... One Year 1 14 8

\* In consequence of the new postal arrangements, the Annual Subscription for India, China, and all foreign countries will now be reduced to £1 14s. 8d., instead of £1 16s. 10d. as formerly.

Post Office Orders and Cheques should be addressed to The Publisher, THE LANCET OFFICE, 423, Strand, London, and crossed "London and Westminster Bank, St. James's-square."

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance. Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 66, Rue Caumartin, Paris.

# "TABLOIDS" OF COMPRESSED DRUGS.

"TABLOIDS" of Compressed Drugs afford a means for *economising time, trouble, and expense* in being *easily prescribed and dispensed*, with the greatest degree of accuracy in dosage attainable.

They are dispensed by chemists at a cheaper rate than either pills or powders because they cost less, when the length of time occupied in dispensing the latter is taken into consideration.

The tired general medical practitioner after a hard day's work at visiting considers them a boon for dispensing, since they facilitate immensely the quick despatch of the medicines, and enable him to secure a little rest from his arduous duties. "Tabloids" are supplied in neat little vinaigrette bottles, suitable for dispensing, and in bottles of 100, from which they may be dispensed in any quantity desired.

Chemists dispense any number ordered in the prescription.

The "Tabloids" are prepared with the finest drugs obtainable only, and contain each exactly the amount indicated on the label.

The "Tabloids" are especially acceptable to fastidious patients, for it has been frequently observed that many who are unable to swallow a pill can take a "Tabloid" with the greatest facility.

"Tabloids" of insoluble drugs are prepared so that they fall to a fine powder in the stomach when swallowed entire, and thus render absorption of the remedy prompt and certain.

"Tabloids" of Cascara Sagrada, Quinine, Pil Rhei Co., &c., are supplied, when specially ordered, coated with pure white sugar. These coated "Tabloids" are much more readily soluble than pills, and are more easily swallowed, reliable, and elegant in appearance.

In the following list those "Tabloids" coated with sugar are indicated by an asterisk.

## LIST OF "TABLOIDS" PREPARED BY BURROUGHS, WELLCOME, & CO.

<p>Aconite Tinct., 1 min. Aloin, 1-10 gr. Ammon. Bromide, 5 and 10 gr. Ammon. Chloride, 3, 5, and 10 gr. Ammon. Chloride with Borax. Antacid (Soda Bicarb., Potass. Bicarb., Magnes. Carb., aa 2 gr.; Sodii Chlorid., 3 gr.) *Anti-Constipation (Aloin, 1-5 gr.; Belladonna Ext., 1-3 gr.; Strych., 1-60 gr.; Ipecac., 1-16 gr.) Antifebrin, 2 gr. Antimony Tartrate, 1-50 gr. Antipyrin, 5 gr. Apomorphine Mur., 1-50 gr. Arsenious Acid, 1-100 and 1-50 gr. Atropine Sulph., 1-100 gr. Belladonna Tinct., 1 min. Bismuth Subnitrate, 5 and 10 gr. Blue Pill, 8 gr. Borax, 5 gr. Caffeine Citrate, 2 gr. *Calcium Sulph., 1-10 gr. Calome, 1-10, 1/2, and 1 gr. Capsicum Tinct., 1 min. *Cascara Sagrada Ext., 2 gr. *Cascara Comp. (Cascara Ext., Dry, 1 gr.; Euonymin, 1/2 gr.; Nux Vomica Ext., 1-16 gr.; Ext. Hyoscyamus Dry, 1-3 gr.) *Cathartic Comp., U. S. P. (Ext. Coloc. Co. Pulv., 1-1/3 gr.; Hyd. Subchlor., 1 gr.; Cambogia Pulv., 1/2 gr.; Ol. Mentli. Pip.) Charcoal, 5 gr. Chloralamid., 5 gr. Chloral Hydrate, 5 and 10 gr.</p>	<p>Cocaine Mur., 1 gr. (Voice). Cocaine with Potash and Borax Grotto Aromat. cum Oplo Pulv., 5 gr. (Aromatic Confection with Dialysed Iron, 10 min. (Opium.) Digitalis Tinct., 1 min. Digitalin, 1-100 gr. Diuretin-"Knoll," 5 gr. Dover Powder, 1/2 and 5 gr. Euonymin Resin, 1-8 gr. Exalgin, 2 gr. Ferrum Redactum, 2 gr. Gregory Powder (see Rhubarb Comp. Pulv.) Galacum and Sulphur Hydrarg. cum creta, 1-8, 1/2, and 1 gr. Hydrarg. Iod. Rub., 1-20 gr. Hydrarg. Iod. Vir., 1-8 gr. Hydrarg. Perchlor., 1-100 gr. Hydrarg. Subchlor. (Calomel), 1-10, 1/2, and 1 gr. *Hydrastin Comp. (Hydrastin Mur., 1/2 gr.; Ergotin, 1/2 gr.; Cannabin Tannate, 1/2 gr.) Ichthyol, 2 1/2 gr. (Powder). Ipecac. and Opium, 5 gr. (Dover Ipecac. Powder, 1-10 and 5 gr.) Iron and Arsenic Comp. (Quinine Bisulph., 1 gr.; Iron Hypophosph., 2 gr.; Arsenic, Strychnine Sulph., aa 1-50 gr.) Iron and Quinine Cit., 3 gr. *Laxative Vegetable (Res. Podoph., Ext. Hyosc., Ext. Tarax., aa 1-4 gr.; Ext. Coloc. Pulv., 1 gr.; Jalapa Pulv., Res. Lepand., aa 1-3 gr. Ol. Mentli. Pip.) Lithia Co. (Dr. Lane's formula).</p>	<p>Lithia Carbonate, 2 gr. Manganese Dioxide, 2 gr. [1-3 gr. Morphia Sulph., 1-100, 1-20, and Nasal (antiseptic and alkaline). Nasal (alkaline). Naso-pharyngeal (Sodium Chlorid., Borax, Boric Acid, Benzoic Acid, Menthol, Thymol, Ol. Gauthieria, Cocaine Mur.) Nitro-glycerine, 1-100 gr. (see also Trinitrine). Nux Vomica Tinct., 1 min. Opium Tinct. (Laudanum), 2 min. Papain, 2 gr. (Dr. Finkler &amp; Co.) Pepsin (Fairchild). Pepsin, Saccharated, 5 gr. Peptonic (Pepsin, Zymine, and Lactophosph. Lime, p. aq.) Phenacatin, 5 gr. Pilocarpin Mur., 1-20 gr. Podophyllin Resin, 1/2 gr. Potass. Bicarb., 5 gr. Potass. Bromide, 5 and 10 gr. Potass. Chlorate, 5 gr. Potass. Iodide, 5 gr. Potass. Nit. (Sal Prunella), 5 gr. Potass. Permanganate, 1 and 2 gr. Quinine, 1-10 gr. and 1/2 gr. *Quinine (Soluble), 1, 2, 3, and 5 gr. Reduced Iron, 2 gr. Rhubarb, 3 gr. *Rhubarb Comp. (Pill), 3 gr. (Rhei. Pulv. 1/2 parts; Aloes Soc. Pulv., 1 part; Saponis Pulv., 6-8 parts; Myrrha Pulv., 6-8 parts; Ol. Mentli. Pip.) (Powd.), 5 gr. Rhubarb Comp. Pulv. (Gregory</p>	<p>Rhubarb and Soda, 5 gr. (Rhei., 3 gr.; Soda Bicarb., 2 gr.; Zingiber. 1/2 parts.) Saccharin, 1/2 gr. Salicin, 5 gr. Salol, 5 gr. Santonin, 1/2 gr. Soda Bicarbonate, 5 gr. Soda-Mint, or Neutralising "Tabloids" (Soda Bicarb., 4 gr.; Ammon. Carb., 1/2 gr.; Ol. Mentli. Pip., 1/2 gr.) Soda Salicylate, 3 and 5 gr. Strophanthus (2 minims of Tinct. in each). Sulphur Comp. (Sulph. Precip., 5 gr.; Potass. Bitart., 1 gr.) Tannin, 2 1/2 gr. Test Tabloids (Fehling's). Thirst (Effervescent). Tonic Comp. (Iron Pyrophos., 2 gr.; Quinine Bisulph., 1 gr.; Strychnine Sulph., 1-100 gr.) Trinitrine (Nitro-glycerine), 1-100 and 1-50 gr. Trinitrine and Amyl Nitrite. Trinitrine Comp. (Trinitrine, 1-100 gr.; Nitrite of Amyl, 1/2 gr.; Capsicum, 1-50 gr.; Menthol, 1-50 gr.) Urethane, 5 gr. Voice (Potash, Borax, &amp; Cocaine). Warburg Tincture, 30 min. in each. Zinc Sulphate, 1 gr. Zinc Sulpho-carb. 2 gr. Zingib. Fort. Tinct., 5 min. Zymine (Pancreatin). Zymine Comp. "Tabloids" (Zymine, 2 gr.; Bismuth Subnit., 2 gr.; Powd. Ipecac., 1-10 gr.)</p>

## CASSELL & COMPANY'S ANNOUNCEMENTS.

NEW WORK BY ARTHUR P. LUFF, M.D.

**A MANUAL OF CHEMISTRY, Inorganic and Organic.** With an Introduction to the Study of Chemistry. For the Use of Students of Medicine. By ARTHUR P. LUFF, M.D., B.Sc.Lond., M.R.C.P., Fellow of the Institute of Chemistry; Fellow of the Chemical Society; Physician to Out-patients in St. Mary's Hospital, and Lecturer on Medical Jurisprudence and Toxicological Chemistry (late Demonstrator of Chemistry) in the Medical School. With numerous Engravings. Just published, price 7s. 6d.

NEW WORK BY FREDERICK TREVES, F.R.C.S.

**THE STUDENT'S HANDBOOK OF SURGICAL OPERATIONS.**

By FREDERICK TREVES, F.R.C.S., Surgeon to, and Lecturer on Anatomy at, the London Hospital; Member of the Board of Examiners of the Royal College of Surgeons; Examiner in Surgery at the University of Cambridge. With 94 Illustrations. Now ready, price 7s. 6d.

NEW WORK BY A. W. MAYO ROBSON, F.R.C.S.

**ON GALL-STONES AND THEIR TREATMENT.** By A. W. MAYO ROBSON, F.R.C.S., Professor of Surgery in the Yorkshire College of the Victoria University; Hon. Surgeon to the General Infirmary at Leeds, &c. Illustrated. Now ready, price 8s. 6d.

JUST PUBLISHED.

**A MANUAL OF OPERATIVE SURGERY.** By FREDERICK TREVES, F.R.C.S. With 422 Illustrations by C. BERJEAU. Each Volume contains about 800 pages, medium 8vo. Two Vols., price £2 2s.

NEW WORK BY G. E. HERMAN, M.B. LOND.

**FIRST LINES IN MIDWIFERY:** a Guide to Attendance on Natural Labour. By G. E. HERMAN, M.B. Lond., F.R.C.P., F.R.C.S. Now ready, price 5s.

NEW WORK BY J. BLAND SUTTON, F.R.C.S.

**SURGICAL DISEASES OF THE OVARIES & FALLOPIAN TUBES,** including Tubal Pregnancy. By J. BLAND SUTTON, F.R.C.S. &c. With 118 Engravings and 5 Coloured Plates. Crown 8vo, 544 pages. Now ready, price 12s. 6d.

CASSELL & COMPANY, LIMITED, LUDGATE HILL, LONDON.

ABSTRACT OF TWO

Lectures

ON

POTT'S DISEASE OF THE SPINE.

*Delivered at the National Orthopaedic Hospital, London,  
on May 9th and 10th, 1892,*

By E. MUIRHEAD LITTLE, F.R.C.S. Eng.,  
SURGEON TO THE HOSPITAL.

IT would be futile to attempt to discuss fully in one or two lectures the history, etiology, pathology, symptoms and treatment of Pott's disease, and I shall not try to do so, but will confine myself chiefly to a consideration of some of the more important points in the diagnosis and treatment of this malady. Caries of the spine was known to the ancients and is mentioned by Hippocrates, but it was reserved for Percival Pott in 1779<sup>1</sup> to fully describe it. It has long been considered to be associated with the strumous diathesis and is now, in common with other strumous bone troubles, recognised as a local manifestation of tuberculosis, though we may be hardly prepared to find that out of 185 cases in which this point was investigated by Gibney of New York he got a history of tubercle in one or both parents in 76 per cent. Both sexes are liable—males slightly preponderating, according to most authors. The disease is rare during the first two years of life, the third year being that in which the onset most frequently occurs, and the frequency diminishes in each succeeding lustre; and, although there is a general agreement among authors as to this relative liability, the figures given differ remarkably. An analysis of the last 320 cases treated at this hospital shows that there were 151 males and 169 females. Of these cases 115 occurred in the first five years of life, and 200 before the end of the tenth year. After adult age cases are rare; the onset may, however, occur at any age, up to even seventy-three, as recorded by Dr. Ogle in the case of a well-known ecclesiastic.<sup>2</sup> Which region of the spine is most frequently attacked? There is no doubt that the dorsal region is by far the most liable. All observers are substantially agreed on this point. The lower six dorsal vertebrae are more often attacked than the upper six, or than the lumbar or cervical region. The lumbar region comes next in order of frequency, and last the cervical.

Like other strumous bone troubles Pott's disease is often the outcome of the inflammatory reaction following on some perhaps slight injury and it most often happens that the patient's friends consider the disease as the result of a fall or tell you that it comes of his having been dropped by a nurse. In 845 cases Taylor found a history of injury in 53 per cent (447). It should, however, be borne in mind that all active children are liable to falls and I believe that if the parents of a large number of healthy children between the ages of two and ten years were interrogated more or less severe falls during the previous twelve months would be recorded in a large percentage, if not in 50 per cent. of cases. The disease may have its seat in the bodies or the arches of the vertebrae. These latter are rarely affected and their destruction in whole or part does not produce the serious deformity that follows destruction of the bodies. I have here several sequestra removed from the right lamina of the seventh dorsal vertebra in a girl aged fifteen now in the hospital.

Abscess is in my experience not so common a complication of Pott's disease as is generally supposed and among 187 cases treated here as out-patients I find only 7 in which abscess is recorded. Among in-patients abscess is far more common (21 in 133 cases), evidently because many cases are admitted because they have abscesses, which otherwise would be treated as out-patients. Pus must in most cases be formed during the course of the disease and the records of post-mortem examinations show that abscess frequently exists without any external evidence of its presence being given. Thus Mohr found abscess in 30 out of 61 necropsies and Nebel in 56 out of 82. An abscess may reach the surface in the pharynx in the case of cervical caries, in the loin in lumbar or dorsal disease, and following the sheath of the psoas may appear in the groin or at any point below Poupart's

ligament. Abscess may cause obvious swelling in the anterior surface of the abdomen, or may pass over the crest of the ilium and appear on the buttock. Abscesses have also been known to make their way into the lung, trachea, bronchi, alimentary canal, or bladder, or burst into the peritoneum or larger vessels. These abscesses contain pus, serous or sero-purulent fluid, or cheesy or cretaceous matter and sequestra. Spontaneous cure is the end of the majority of vertebral abscesses, if we include those which give no external sign of their presence.

For convenience the course of the disease may be divided into three stages—(1) Inflammatory; (2) loss of substance; and (3) consolidation. In the earlier stages of Pott's disease, before there is any loss of substance, the symptoms are so vague and so often overlooked that, especially among the lower middle and working class, advice is seldom sought until there is obvious deformity. Pain, localised or referred to the periphery of the spinal nerves, is not in my experience a common symptom at any stage of the malady, and it is surprising that such extensive disease, involving one of the most important bony structures of the body should be so little painful. Tenderness on pressure over the spinous processes is also rare, and the hot sponge described as a test in many surgical text-books is of little diagnostic value. Peculiarities of gait and attitude and departures from the normal in the mobility of the head and trunk are the symptoms which are the most characteristic. In whatever part of the vertebra or vertebrae the disease begins the affection sooner or later reaches a part where the inflamed structures are interfered with by motion and the irritation caused by movement tends to aggravate the inflammatory process. The efforts of nature, as in hip-joint disease, seem directed towards procuring physiological rest for the part by the involuntary contraction of the appropriate muscles. Hence in the spine, as in the hip, we have stiff joint as an early symptom due to muscular action and stiff joint as a final result due to ankylosis. The parallel holds good, although Pott's disease is not primarily a joint affection. This contraction of the muscles produces rigidity of the part of the spine affected and often of the greater part of the column. The wider the range of movement in health the more marked and obvious is the stiffness in caries. Consequently, when the cervical region is the seat of disease the stiff neck is at once noticed by the friends, whereas in the dorsal region rigidity may be overlooked for months until the case is examined by a surgeon. The patient in the early stage of cervical caries—say, in the middle of the region—if directed to look over one shoulder turns his whole chest, the movement occurring in the loins and hips. Flexion and extension of the neck is no longer practised. Nodding, although limited, may be possible, and if the upper cervical vertebrae are affected voluntary flexion and extension are impossible, the head and neck forming one rigid rod. A characteristic attitude seen in some cases of cervical disease is that in which the patient rests his elbows whenever he can possibly do so, and takes the weight of his head off the inflamed structures by supporting it in the palms of his two hands. He sometimes, if a child, "squats" in oriental fashion and stooping forwards holds his head while his elbows rest on his knees. Patients with caries in the neck walk with a peculiar air of anxiety and, carefully avoiding any jar or shock, may be said, like Agag, to go delicately.

In the first stage in the dorsal region the patient will avoid bending the back, and if the disease be severe it will be noticed that he takes some of the super-incumbent weight of head and upper extremities off the inflamed structures by resting his hands on the seat of the chair on which he sits, on a table or on any available object. Sometimes the child will lean the body (without bending it) forwards and rest his hands on his thighs, the hip and knees being slightly bent. If a patient is asked to pick up anything from the floor he will generally keep the trunk perpendicular and sink down by bending the knees and hips until his hand is within reach of the ground. This is very characteristic. With disease in the lumbar region the gait and posture are much the same as in the dorsal, but the upper part of the spine is less rigidly fixed. In the lowest dorsal and lumbar region, psoas contraction is apt to occur and this may be the only marked symptom besides rigidity. This contraction causes lordosis if the patient is old enough to walk about. If you tell the patient with dorsal caries to try to touch his toes without bending his knees—and this test is not available in young children—he will be able to go only a very little way and will keep his back stiff, and in lumbar caries this stiffness is still more marked. If a child suspected of Pott's disease be laid

<sup>1</sup> Remarks on that kind of Palsy affecting the Lower Limbs.

<sup>2</sup> Pathological Transactions, vol. xv., p. 20.

prone on a couch and the surgeon holding the ankles lift the lower extremities and pelvis while the upper part of the chest remains on the couch on which it rests as a fulcrum, should the spine be of normal mobility a general curve will be formed from the shoulders to the hips, while the thighs will be further extended. In Pott's disease, however, the trunk will remain rigid and the thighs slightly flexed and the patient generally resists the manoeuvre. Pain is very variable in the first stage of Pott's disease. In some cases the child cannot be moved without pain and the friends will say that it never seems easy and constantly cries unless it is lying down. In some children night cries occur; in others pain may be referred to the distribution of the spinal nerves of the part. Thus with disease about the seventh dorsal vertebra epigastric pain is complained of and sometimes vomiting occurs; in others there is pain over the hip (twelfth dorsal), and in lumbar disease the anterior crural or other lumbar nerves may be irritated and pain be referred to the thigh &c. In general the story told is that the patient has been ailing for some months, has been fretful and easily tired, and cries when moved roughly, but no very sharply localised pain is often complained of. The classic test, which consists of making the patient jump off a small height on the heels or drop on to the heels from tiptoe is not to be recommended; if there be active disease it will do harm, although, as a rule, in such a case the patient will not put it in practice when told to do so, and it is not always easy to get a healthy child to do it. The practice of pressing on the head in suspected disease high up is equally to be condemned and is yet more dangerous. As the first stage merges into the second alterations in the form of the column occur, causing in the dorsal region an exaggeration, in the cervical and lumbar an obliteration, of the normal curves or their reversal. Before this has gone very far all doubt of the nature of the disease is set at rest when the other usual symptoms are considered. One spinous process is soon found to project from the line, forming a boss, and as the bodies of the vertebrae on each side of the area of destruction fall together other spinous processes on either side become more prominent until a knuckle-like angle is formed. But it must not be forgotten that an irregularity of the line of spinous processes or marked projection of one or more of these is perfectly consistent with health. In that case, however, there is normal or sometimes more than normal mobility. This irregularity is, however, very different from the pronounced salient angle which develops in the later part of the second stage. But projection of one or more spines in the dorsal region, below the first two dorsal, is almost always pathological and presumptive evidence of caries. It is commonest in the lumbar region.

The backward projection in Pott's disease is not infrequently accompanied (as Lovett of Boston, U.S., has pointed out) by a lateral deviation from the mid line and a mistaken diagnosis may be made in such a case. The mobility of the column in slight or moderate lateral curvature and its rigidity in caries should prevent mistakes. Also rotation of the spine is absent in caries. Strain of the back may suggest early Pott's disease. If there be any doubt in such a case it must be treated as though caries were present. Time will clear up the doubt. In the posterior curvature which occurs in rickety infants there is generally mobility enough to exclude Pott's disease, but in some cases the differential diagnosis is not easy.

In disease of the cervical vertebrae the head is sometimes held awry, and such a case may be mistaken for torticollis. The freedom of movement within certain limits in the latter deformity quite negatives caries. A careful examination of the parts will, by showing the seat of the trouble, help to distinguish between hip disease and psoas-contraction in lumbar caries, or between the latter and sacro-iliac disease. In hysteria rigidity of the spine may simulate Pott's disease. The hyperaesthesia and absence of the typical symptoms of caries, such as resting the weight on the hands and the detection by careful observation of mobility when the patient is off her guard, will help in diagnosis. In rheumatism of the spine the local pain and the long-standing rigidity, without angular deformity besides the general constitutional state, are the chief guides to a diagnosis. That the diagnosis is not always easy is shown by the occasional occurrence of lamentable mistakes, as in a case reported by Mr. Edmund Owen.<sup>3</sup> In Dr. Ogle's case, before referred to, no suspicion existed during life of the extensive disease of

the axis and neighbouring parts which was found after death.

As a means of recording the progress of the deformity an outline of the contour of the spine should be taken by means of a flexible strip of lead, which is applied to the back—preferably while the patient is lying down—so as to lie closely in contact with the skin over the apices of the spinous processes. This strip of lead must be stiff enough to retain (with careful handling) the form thus acquired and is to be used as a guide to pen or pencil when laid on its edge on a piece of paper. The outline thus obtained is preserved for comparison with future ones. Another way of using the outline is to trace it on a piece of cardboard. The card is then cut through along the line, and the template thus formed is applied to the spine. If it does not exactly fit it must be modified by means of scissors. When accurate it is to be kept as a means of detecting the slightest alteration in contour. In dealing with very young children it will be found convenient to warm the lead to the temperature of the skin by immersion in a bowl of warm water. In the third stage the angle has reached nearly its maximum and the spine consolidates and only a slight alteration takes place in the contour here, but changes occur in the healthy parts of the spine, producing what are known as compensatory curves. These may go on increasing for years after active mischief has ceased.

The treatment of Pott's disease in its active phases, like that of other inflammatory bone or joint mischief, should be mainly directed towards securing complete physiological rest for the injured part, and in most cases all that is needed is to second the efforts of the patient, both voluntary and instinctive, which are directed to the same end. In a disease which tends so often to end in spontaneous recovery—we have had six deaths from all causes in 133 cases admitted as in-patients—radical operative measures on a part so deeply seated as the anterior half (the vertebral bodies) of the spinal column can seldom be justifiable; and although, since Israel's operation in 1882, Treves and others have operated on the seat of the bone lesion in a good many cases, the results are not such as to make the operation preferable to expectant treatment in most cases. In practice it is only in the lumbar region that the bodies of the vertebrae are at all freely accessible; and in the dorsal region, which is attacked in so large a proportion of cases, it is only by resection of ribs that the operation is feasible. It is also extremely difficult to remove the diseased parts thoroughly and safely, and without this an operation must be looked on as a failure. Rest—i.e., arrest of motion of the diseased part—is sought after in various ways, each of which has its advantages, by recumbency, by extension and fixation. Complete recumbency in the supine or prone position is advisable, for a time at any rate, in the first stage of disease in most cases, while in the severe cases, where there is marked constitutional disturbance it is a *sine qua non*. Its advantages are that it is simple, requires no apparatus and no special skill to carry it out, while it removes the weight of the parts above from the affected part of the spine to a more complete extent than any portable apparatus can do. Its drawbacks are that it prevents the patient taking exercise, that it is in young children difficult sometimes to maintain, and that the confinement to bed that it involves may be prejudicial to their health and may retard or prevent recovery. In most cases in the early stage patients are better without exercise, and by the use of the bed frame children can be easily prevented from sitting up. The bed frame consists essentially of two blunt hooks of  $\frac{3}{4}$ -in. iron rod jointed at the shank ends to a flat iron bar, the length of the distance between the patient's axillae (shown). The upper ends of the arms rest in these hooks, to the extremity of each of which a padded strap is fixed, which passes over the shoulders and buckles to the shank of the hook. The flat iron bar rests on the bed, below the nape of the neck, and the whole is attached to the head of the bed by simple means. Though principally meant to be used as a means of counter-extension when weights are used it is useful in simple continued recumbency to restrain young patients without interfering with the use of the arms. Extension may be made by weights attached to the feet, the bed frame being used for counter-extension, or the weight of the body, when the foot of the bedstead is raised up, may itself supply the counter-extending force. Instead of thus hanging, as it were, the body by the feet, which has obvious disadvantages, we may hang it by the head and upper extremities and this can be most conveniently done by using the suspension couch. This

<sup>2</sup> THE LANCET, Jan. 30th and Feb. 20th, 1892.

allows constant extension to be practised while the patient is in the sitting or reclining position, a method of treatment introduced by my colleague, Mr. F. R. Fisher, in 1877.<sup>4</sup> This method has the great advantage that the patient when in the sitting position can see what goes on around in the daytime, while at night he can be lowered almost to a horizontal position. The exact regulation of the amount of extension is easily made by means of the rack-and-pinion movement. Another means of applying extension and in children a most convenient and efficient one is the box known by the name of Dr. Phelps of New York. This consists essentially of a Y-shaped trough of wood, suitably padded. The body of the child occupies the trunk of the Y, the lower limbs the two branches. The sides of the box are cut away just below the shoulders of the patient to allow his arms free play and the bottom is also cut away below the buttocks to facilitate the use of the bed-pan. By means of occipital and chin straps regulated by buckles counter-extension can be made, the body weight acting as an extending force when the head end of the box is raised up, or by means of the anklets and cords extension can be made by pulling on the feet. The patient I now show you has been in such a box, modified by Mr. Ernst, for some weeks. The box is very light and easily carried about, and a child can even be taken to school in it and given as much fresh air as climate and situation allow. Experiments on the cadaver, both normal and affected with spinal curies, show that no practicable amount of force will effect immediate separation of the surfaces of the affected bones. I cannot but believe, however, that continuous and uninterrupted extension with only a few pounds weight, and still more so when a large part of the weight of the trunk is employed, must in time, by tiring out the muscles, succeed in reducing or nullifying the pressure between the diseased elements of the spinal column. Clinically extension is most useful and its results encouraging. Fixation of the spine is sometimes attempted in the active stage by the application of gypsum jackets or by some other portable appliance. In most cases fixation or attempted fixation is ineffective unless the mischief be situated towards one end of the column.

In the later stages of Pott's disease portable appliances have their true and best uses. These consist of gypsum, poroplastic felt, leather or wooden &c. jackets or instruments made of steel and leather. These have as their object to support the spine and prevent further bending of the affected portion, and it is claimed for some of them that not only may the deformity be reduced by their employment but even in some cases totally removed. It has never been my good fortune to see this result. The gypsum jacket has the great advantage of low cost and simplicity, needing the help of no instrument-maker in its application and being made of common and easily obtainable materials. On the other hand, it is heavy and in its simplest form not removable and consequently dirty and disagreeable. It may, it is true, be made to open and lace down the front, but is even then not adjustable to any great extent, and if much modification, owing to changing conditions of the spine &c., is wanted a new jacket must be made. In consequence of objections the gypsum jacket is very rarely ordered in this hospital, where the poroplastic felt jacket may be said to have quite taken its place. This material has the advantages of lightness, great plasticity when softened by steam heat, sufficient rigidity at the body temperature and consequent adaptability to changing conditions, and the jacket is easily removable. It should be applied while the patient is suspended. A properly designed and constructed steel support is perhaps the best possible appliance for convalescent or consolidated Pott's disease, but it has the disadvantages common to all elaborate instruments that it needs special skill and experience on the instrument maker's part and also on the surgeon's to secure a good result. Jackets and steel supports, unless they extend to the head and thus relieve the spine below of some of the weight of that organ, are of little or no effect as a means of longitudinal extension, and in children, even with the head-piece or jury-mast, the pelvis is so little developed that it is difficult or impossible to get a proper basis or point of support for counter-extension. These appliances must therefore be chiefly useful as a means of extending the spine in the sense of diminishing the abnormal curve or angle, in the same way that a splint is sometimes used on the outer convex side of the leg to straighten a curved tibia. Gypsum and poroplastic jackets can, however, do little more than support the trunk, while a steel support may be made to press on the projecting

angle, and by means of a pelvic band and shoulder-straps and a laced chest-piece counter-pressure at the ends of the lever can be obtained and further deformity be more surely prevented, or the existing angle be perhaps in some cases diminished.

In cervical and upper dorsal disease an extension of the apparatus to the head is imperatively needed, and for this purpose the occipital support with the chin and forehead straps is better than the overhead jury-mast, in that it more thoroughly immobilises and extends the cervical spine by using the occipital piece as a point of support for the head. It is also less unsightly and far less in the way. In high cervical disease one of the forms of collar which transfers the weight of the head to the shoulders may be used late in the disease, while in the acute stages recumbency, with sandbags to support the neck and prevent movement, is a classic and effective treatment, and the higher the disease the more complete should the rest be. A small, firm pad, as Mr. Hilton long ago pointed out, should be placed under the upper part of the neck to support the vertebra in the normal anterior curve of that part and in atlo-axoid disease—happily rare—to prevent pressure on the medulla by displacement of the odontoid process.

In the dorsal region (lower two-thirds) Phelps's box or recumbency, with extension by bed frame and weights, is the best treatment during the active stages of the malady. When consolidation begins a poroplastic jacket or well-fitting steel support is advisable. In the loin disease as a rule results in less deformity than elsewhere, because an obliteration or even reversal of the lumbar curve is much less obvious in its effects on the appearance and attitude of the body than alterations of form in the neck or chest, and the alterations of the normal loin curve are not often great, no doubt because (as Bradford and Lovett point out) the bodies here are very large and are not often completely or even extensively eaten away by the disease. In this region simple recumbency gives good results, while it is obvious that, owing to the nearness of the trouble to one end of the lever, it is difficult to exert antero-posterior extension by supports. Owing, however, to the length of the unaffected parts of the spine above, of which we can take hold by a jacket or instrument, mechanical support is more efficient here than in the dorsal region. A poroplastic jacket may be made by careful moulding and firm lacing to fit to the ribs at the sides and back so closely as to offer considerable support to the upper part of the trunk, some of the weight of which is thus transmitted to the hips direct. All jackets and instruments should be removed at night or at other times when the patient is recumbent, because they are not then needed, and also to allow the chest walls full play and counteract, as far as possible, the necessarily constricting effects of the jacket during the time it is worn. The "life" of a jacket is also prolonged by thus saving unnecessary wear and tear.

After consolidation is complete little or no change occurs in the gibbosity formed by the ankylosed vertebra, or remains of vertebra, but gradual changes in the "compensatory" curves which occur in the sound parts of the column above and below the projection go on for some time, unless prevented by a well-fitting and firmly applied support. These compensatory curves are the result of the erect position, in which without them the centre of gravity of the body and especially of head and upper extremities would be placed too far forward for stability; the gibbosity is therefore thrown backwards and the vertical through the centre of gravity made to fall within the base by the curves above and especially below (lordosis), but in some cases of dorsal disease instead of compensatory curves the lines of the angle are continued as it were above and below, and the whole trunk is thrown backwards by movement in the loins and at the hips, so as to attain equilibrium and much to exaggerate the apparent deformity; a proper support should prevent this. The chief complications are abscess, paralysis, psoas contraction. Abscess is a serious complication of Pott's disease and four modes of dealing with it present themselves: (1) Expectant treatment; (2) repeated aspiration; (3) injection of fluid to promote absorption; (4) incision. Expectant or, as it may be called, passive treatment should always be tried and persisted in as long as an abscess is not rapidly increasing or showing a disposition to point, and not a few chronic cases will do well under this treatment. It must be remembered that psoas and, in a less degree, lumbar and iliac abscesses differ in many circumstances from those in other parts of the body and those from other causes, and cannot often be dealt

<sup>4</sup> Essays on the Treatment of Deformities, Churchill, 1870.

with according to the general rules of surgery. In the first place the sac cannot freely be laid open nor the tissue lining it be safely completely excised. The channel communicating with the focus of disease is a long one and often tortuous, and there are often diverticula and other sacs communicating with that which is apparent externally by perhaps minute openings. Add to this the neighbourhood of important structures and the difficulties in the way of radical treatment are at once appreciable. In some cases, when an abscess has existed for a long time, it may have become cut off from its original source and be nothing more than a localised collection of pus, which is easily cured by incision. Aspiration will only remove the serous or more fluid parts of the contents, leaving the cheesy or curdy masses, which are more important, behind, and even evacuation of the fluid by aspiration may be hindered by the blocking of the needle by flakes of lymph or curdy masses. Aspiration, however, will, by reducing tension, put off the evil day of rupture. With antiseptic precautions simple incision, repeated if needed, is to be preferred to aspiration. Injection with iodoform glycerine or iodoform and ether is a means of treatment that has lately found favour in Germany—from 30 to 100 grammes (seven to twenty-five ounces) of a 10 per cent. solution being injected through an aspirator needle, the abscess having previously been emptied. Bruns claims fifty cures in fifty-four cases, and the treatment appears certainly worthy of trial. Iodoform poisoning is stated hitherto not to have been observed. For retro-pharyngeal or retro-oesophageal abscess incision is the best treatment, on account either of accessibility or danger to life. In lumbar abscess incision is more useful than in psoas abscess, as the sac is likely to be less extensive and complicated, and drainage is here much more complete. Lumbar incision may also advantageously be practised in abscess pointing in the groin, an incision being made at the outer side of the transverse processes of the vertebrae in the loin through the fibres of the quadratus lumborum. Pressure on the abdomen and groin will cause bulging of the sac, which may then be probed by an aspirator or grooved needle and then freely opened; if easily accessible the carious vertebrae may at the same time be attacked and scraped. Israel's case was of this kind; the canal was opened, liberating pus, but the patient died from empyema. In slow chronic cases, despite risk of lardaceous disease, a less heroic treatment is to be recommended.

Paraplegia as a complication of Pott's disease too often occurs, although in 133 cases treated here as in-patients I find it noted in only 10; paresis is mentioned in 8 cases. Of the 10 cases 7 recovered, while of the paresis cases 6 are recorded as recovered, no mention being made in the seventh of the paresis; probably it had disappeared. The lower extremities generally alone suffer, motor power being often completely lost, while sensation may be impaired but is seldom lost. Control over the sphincters of the anus and bladder is often lost; the knee-jerk is generally absent. The upper extremities are also in cervical disease occasionally palsied, yet they may recover. Spontaneous recovery under rest treatment is the rule even after a very long interval. The cause of the palsy is generally a pachymeningitis and not displacement of the vertebrae. Hence the contrast in prognosis between palsy from injury (fracture dislocation) and that from caries.

In the treatment of paraplegia rest and extension produce the most encouraging results. They may be applied when the disease is lower dorsal or lumbar, by weight extension in the recumbent position, or when it is above this by suspension from the head, and, if the body be heavy, also by the arms. The adult patient (twenty-two) you have just seen has been treated by the former method, the child whom you see by the latter method. Both had complete motor paralysis and loss of knee-jerk on admission and improved in general health under treatment. In the case of the child returning power was evident after a fortnight. Both can now (in July) walk about. I suppose that the improvement is not due to rest alone, from the rapidity with which improvement has set in when extension was applied, rest having, at least in the man's case, been previously tried. I presume that extension, by removing irritation and diminishing intervertebral pressure, allows the organism a chance to absorb the inflammatory products and thus alleviates pressure, more than by any possible straightening out of the distorted canal. Macewen advocated operative interference in pressure paralysis and operated by removing the laminae and spinous processes. This operation has now been done some score of times, with a fatal or negative result in many cases.

It is probable that some at least of the successful cases would have recovered under other treatment, and, as Lovett and Taylor have recorded, that when palsy came on under treatment every case studied by them recovered, and that of all cases 83 per cent. recover without operation, it must be plain that the field for operation is a narrow one, applicable to otherwise hopeless cases. After years of palsy even patients may recover without operative interference. In one case under my care recovery occurred after two years of palsy. Contraction of the thigh sometimes occurs in dorsal or lumbar disease where psoas contraction has been marked, and prevents the patient's reaching the ground with the affected limb without flexing the whole trunk forwards, as compensatory lordosis, such as occurs in hip disease is either prevented by ankylosis or else the whole available mobility is employed in compensating for the dorsal gibbosity. To prevent this contraction extension should be applied early wherever flexion of the thigh exists. When deformity from contraction remains section of the offending muscles and fasciæ subcutaneously should be practised. In some cases it may be necessary to operate on deeper structures, which can only safely be done by open incision. The limb must be kept extended by a splint for some time. This splint may form part of any support fitted to the trunk so as to allow walking.

---

A REPORT ON  
THIRTY-SEVEN CASES OF TUBERCULOUS  
DISEASE OF THE HIP-JOINT,  
FOR WHICH EXCISION OF THE JOINT WAS PERFORMED  
IN THIRTY-SIX CASES.

BY BILTON POLLARD, M.D., B.S. LOND., F.R.C.S. ENG.,  
ASSISTANT SURGEON TO UNIVERSITY COLLEGE HOSPITAL AND SURGEON  
TO THE NORTH-EASTERN HOSPITAL FOR CHILDREN;

AND  
C. F. MARSHALL, M.D., CH. B. VICT.,  
HOUSE PHYSICIAN TO THE METROPOLITAN HOSPITAL, KINGSLAND-ROAD,  
N.E.; LATE SENIOR HOUSE SURGEON TO THE NORTH-  
EASTERN HOSPITAL FOR CHILDREN.

INTRODUCTION.

THE treatment of tuberculous disease of the hip-joint after it has advanced to suppuration is regulated by two main schools of thought. One considers it best merely to open and drain the abscesses as soon as they are detected. The other recommends that the abscesses should not only be opened, but that they should be cleared of tubercular material and that the tubercular growth should also be thoroughly extirpated from the joint, notwithstanding the fact that, in order to do so, it is usually necessary to remove the head of the femur. The relative merits of two methods of treatment have been much discussed in recent years, but the advocates of the rival plans are still, so far as we know, unconvinced by the arguments of the other side. *A priori* arguments and general impressions in regard to results will not carry conviction on a subject of this kind. Mere tabular statements of the results are also insufficient. The opponents of a particular method of treatment should be so completely supplied with the facts that they may estimate its merits and demerits for themselves. Such a report should deal with consecutive cases, which have been under treatment in sufficiently recent times to allow of at least the majority of them being traced; for it is surely just as reasonable to assume that untraced cases either are or have been under treatment at other hospitals or even that they are dead as it is to assume that all or the majority of them are cured because they have not applied for further treatment. Nothing further can be said of untraced cases than that they spoil the returns. Having these views in mind, we have not delayed our investigations to a time when the report might suffer conspicuously from untraced cases. This report deals with all the cases of tuberculous disease of the hip-joint which have been operated upon by one of us during the last six years. By making inquiries in the localities where the children used to live we have traced several cases which would otherwise have escaped us. We have only failed to find two patients. We have prepared abstracts of the notes

of all the cases. These, though of necessity short, include, it is hoped, all the important facts in regard to them. The condition of the children when last seen is pretty fully stated, and engravings, executed from photographs, are appended to the reports of the cases when the children have left off their splints and are going about, their wounds being healed.<sup>1</sup> In order to avoid repetition in the reports of individual cases, we shall first of all describe the plan of operation which was followed.

#### DESCRIPTION OF OPERATION.

The abscess, which almost always was found situated beneath the sartorius and tensor vagina femoris muscles, was first freely opened by an incision between these muscles and thoroughly scraped and scrubbed with sponges in order to remove the tubercular growth. The lower part of the abscess was then plugged, whilst the sinus which led into the joint, and which was usually found just above the neck of the femur in the angle between it and the great trochanter, was enlarged sufficiently to give exit to the pus and tubercular débris from the joint and to admit the finger. If the head of the femur was diseased, as it invariably was, the neck of the bone was divided with an Adams' saw and the separated head was raised from the joint with a curved elevator and removed. Care was always taken to divide no more of the Y-ligament than was necessary in order to remove the head of the femur, for it was considered that this ligament was one of the chief agents in limiting the inevitable displacement of the trochanter upwards. The cavity of the joint was then very thoroughly scraped with a sharp spoon and in some cases tubercular tissue was cut away with scissors. In the earlier cases repeated scrubbing with sponges was relied upon for the removal of the tubercular débris, but in the later cases the cavity of the joint was flushed out with water sterilised by boiling alone or, in addition, by perchloride of mercury in the proportion of 1 in 4000 either through Mr. Barker's flushing spoon or through a piece of rubber tubing. The cavity of the joint was then dried and, the wound being held open, a careful examination was made for any remaining tubercular growth with the aid of a strong light thrown into the cavity from a forehead mirror. By this means in a few cases tubercular foci were seen which would otherwise have escaped detection. Iodoform was applied to the joint and the cavity was tightly packed with sponges. After the stitches had been inserted the sponges were removed and the limb held in abduction. The sutures were then tied. In some of the cases a tube was inserted, but in others, following Mr. Barker's lead, no provision was made for drainage. In order to leave the cavity as dry as possible firm pressure was kept up about the joint until the dressing had been securely fixed with a moderately tight bandage. A double Thomas's splint made so as to maintain abduction of the limb was then applied. In the earlier cases the tube was not entirely removed for some weeks, in those about the middle of the series no tube was used, and in the later cases a tube was employed for about twenty-four hours. Immediate excision was not resorted to unless extensive and general disease of the joint was found. In some of the cases it was decided to deal with them as thoroughly as possible without excision, so as to give them a chance of healing without destroying the natural support of the joint. In all these cases with the exception of one, which is not included in this series, it was judged best to excise the joint at a later date on account of the unsatisfactory progress of the case.

The series of cases here reported refer to thirty-six patients. In one case both hip-joints were excised. We have therefore to do with thirty-seven radical operations for the removal of tuberculous disease from the hip-joint. Eight of the patients, or 21.6 per cent., are known to be dead. The mortality directly dependent on the operation was 10.8 per cent. (four patients). Of the remaining four cases two died of intercurrent affections altogether unconnected with tuberculosis and two died from other tubercular complications. There remain for consideration twenty-nine cases. Of these twenty-seven have been followed up; two could not be found. The report has therefore to do chiefly with twenty-seven cases. Seventeen of these are now healed and are going about without splints. They are subsequently referred to as completed cases. The remaining ten cases are still wearing Thomas's splints. Four of these appear to be soundly healed; six have

a sinus. After the reports of the individual cases we propose to give an analysis of them under several headings in order to bring into relief the points both favourable and unfavourable which appear to us to be the most important and instructive.

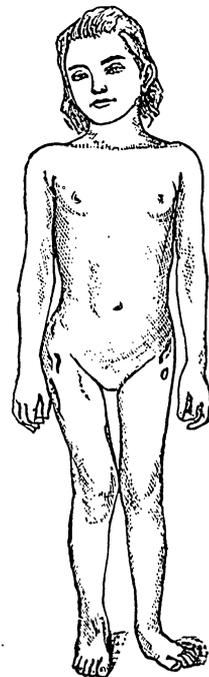

#### COMPLETED CASES.

CASE 1.—C. R.—, aged nine years. Disease of the right hip began at eight years of age. No cause was assigned. There had been no previous treatment. The patient was admitted to hospital one year after the onset of the disease with a large abscess behind the trochanter. The limb was adducted and everted but not flexed. The joint was excised through a posterior incision. The head of the femur and the trochanter were found diseased and the head of the femur and part of the trochanter were removed; the wound was drained with tubes. The temperature was normal throughout. The wound healed by primary union, except at the tube tracks; these healed by granulation two months after operation. There was a recurrence of the disease two years after the operation, the splint having been discarded for nine months. Carious bone was removed from the trochanter. The second and third secondary operations were performed six and ten months after the recurrence, and there was no further bone disease. The fourth secondary operation was performed eleven months after recurrence, an iliac abscess being opened. The fifth secondary operation was fifteen months after recurrence, with no further bone disease. The wound finally healed one year and four months after recurrence and three years and seven months after excision. A double Thomas's splint was worn for nine months after excision and a single Thomas's splint for six months more. The splint was resumed after recurrence and left off sixteen months after final healing. When the patient was last seen, five years and three months after excision (three years and three months after recurrence), the splint had been left off six months. The general health was fairly good. The real shortening was two inches, but the apparent shortening was only half an inch, the difference being due to abduction. The limb could be flexed to 10° and extended to the vertical. The patient walks easily with the aid of a stick. (Fig. 1.)

FIG. 1.

FIG. 2.

CASE 2.—R. B.—, aged seven years. Disease of the left hip began at seven years of age; no cause assigned; treated previously with Thomas's splint for six months; again by weight extension five weeks before admission. Admitted to hospital fifteen months after onset of disease with abscess over trochanter. Limb was flexed and adducted and rotated

<sup>1</sup> Owing to the length of this paper in its original form we are obliged to omit the abstracts of the incomplete cases; also some of the engravings.

inwards. Joint excised by anterior incision; head of femur much diseased; head and part of neck of femur removed; drained with tube. Temperature normal. Healed in three months; no recurrence of bone disease. Small sinus scraped four months after excision. Finally healed five months after excision. Single Thomas's splint worn for twelve months after excision and then left off without sanction. When last seen, five years and two months after excision and four years and nine months after healing, splint had been left off four years and two months. Joint quite sound; real shortening two inches. General health fairly good. Joint could be flexed to 90° and extended to vertical. (N.B.—This patient developed disease of the other hip about four years and a half after excision of the first hip; this was treated at the Evelina Hospital, where the head and neck of the femur were removed. Owing to this the apparent shortening could not be taken, and the patient could not walk without crutches; but with them and a patten on the left foot she could get about comfortably.) (Fig. 2.)

CASE 3.—E. M—, aged six years. Disease of the left hip began at five years of age after a fall; treated with weight extension for two months before operation. Admitted to hospital ten months after onset of disease with a posterior abscess. Limb was then flexed to 30° and adducted 20°; no shortening. The

months and afterwards with weight extension. Admitted nine months after onset of disease with abscess in front of joint. Limb was flexed and inverted; joint excised by anterior incision; head and neck of femur diseased and acetabulum perforated. Head and part of neck of femur removed with a loose sequestrum from acetabulum; no drainage; temperature normal on eighth day; healed by primary union; recurrence three months after excision. Two secondary operations were done three and nine months after excision. Sequestrum removed from acetabulum at the first of these; no further bone disease at the second. Third secondary operation performed a year and ten months after excision; small carious spot in acetabulum. Finally healed one year and eleven months after excision. When last seen, three years and four months after excision, or one year and five months after final healing, splint had been left off eight months. General health good and joint quite sound; real shortening one inch; apparent shortening one inch; no displacement of limb; joint allows flexion to 90° and extension to vertical. Walks easily on sole of foot without support. (Fig. 4.)

CASE 5.—A. P—, aged five years. Disease of the left hip began at four years of age; no cause assigned; no previous treatment. The patient was admitted to hospital a year after the onset of the disease with an abscess in front of the joint;

FIG. 3

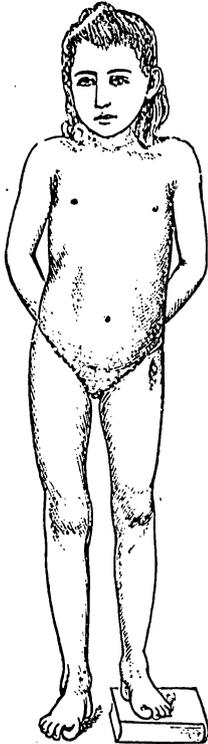

FIG. 4.

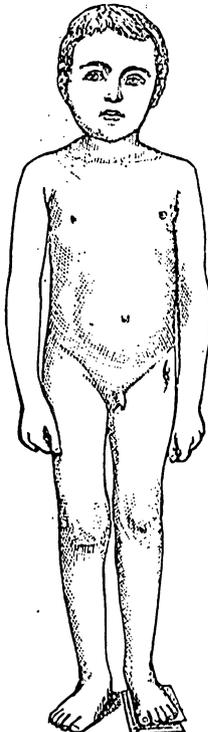

FIG. 5.

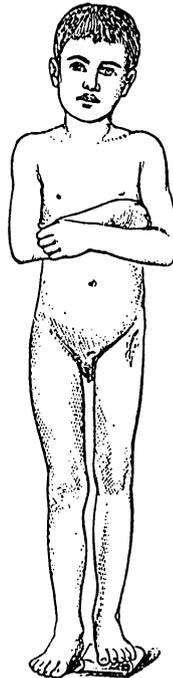

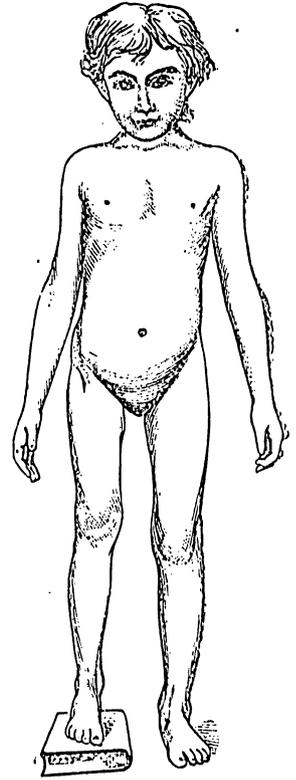

FIG. 6.

abscess was opened and drained six weeks before excision. The abscess track did not heal. Joint excised by anterior incision. Head of femur carious, and removed. Acetabulum only superficially affected. Drained for five weeks. Temperature irregular for three weeks after excision. Healed in seven weeks. Two small secondary operations, one consisting in scraping granulations, the other aspiration of an abscess three and eight months after excision. No recurrence of bone disease. Finally healed about nine months after excision. Splint worn for one year and ten months after excision. When last seen, four years and four months after excision, or three years and seven months after final healing, the splint had been left off about two years and a half. General health good; joint sound; real shortening two inches, apparent shortening one inch and a half; firm fibrous union at an angle of 45°; flexion compensated for by lordosis; difference in apparent and real shortening due to slight abduction. Walking good on toes without support. (Fig. 3.)

CASE 4.—J. M—, aged three years. Disease of the left hip began at the age of two years and three-quarters, after an injury to leg. Previously treated with plaster-of-Paris for three

joint excised through anterior incision; head of femur disintegrated; acetabulum and root of trochanter diseased; head and part of neck removed and trochanter scraped; drained with two tubes; temperature rarely above 101°. Healed by primary union, except at tube track; recurrence fourteen months after excision. Four secondary operations—fourteen, sixteen, eighteen, and eighteen months and a half after excision. At the second of these there was fresh bone disease in the trochanter and upper end of the neck of the femur, with two small sequestra. There was no further bone disease at the last two operations. Wound finally healed about six months after recurrence, and a year and eight months after excision. A Thomas's splint was worn for two years and six months. When last seen, three years and four months after excision, or a year and eight months after final healing, the splint had been left off eleven months. General health good and joint sound; real shortening an inch and three-quarters; apparent shortening an inch and a quarter, the difference being due to slight abduction. The limb could be flexed to 30° and extended to the vertical without movement of spine.

Walks easily on toes without support, and can run about with other children. (Fig. 5.)

CASE 6.—W. B—, aged five years. Disease of the right hip began at three years of age; no cause assigned; previous treatment by weight extension for three months, followed by Thomas's splint for fifteen months. Admitted to hospital two years after onset of disease with abscess in front of and on outer side of joint. Joint excised by anterior incision; head of femur destroyed and upper part of neck carious; remains of head and part of neck of femur removed; drainage for five weeks. Temperature never above 101°; drainage track did not heal; recurrence; two secondary operations four and thirteen months after excision; carious bone removed at each. Wound finally healed fifteen months after excision; a Thomas's splint worn for one year and nine months after excision. When last seen, two years and six months after excision, or one year and three months after final healing splint had been left off nine months; general health good; joint sound; real shortening two inches and a quarter, apparent shortening one inch and three-quarters, difference being due to slight abduction; limb was flexed at an angle of 10°; joint allowed slight flexion and abduction. Walking good on sole of foot. (Fig. 6.)

CASE 7.—C. K—, aged eight years. Disease of left hip began at six years of age; no cause assigned. Treated for nearly two years with a single Thomas's splint. Admitted to hospital two years after onset of disease with an abscess in front of joint. Limb was shortened three-quarters of an inch, adducted and everted slightly, but not flexed; joint excised by anterior incision; head and neck of femur diseased, acetabulum denuded of cartilage, but not very carious; head and neck of femur removed. Wound drained with two tubes for six weeks and a half; temperature only once above 101°; primary union except at tube tracks; no recurrence of bone disease, but residual abscess opened one year and eight months after excision, child having then left off splint five months previously. A double Thomas's splint was worn for seven months after excision, and a single Thomas's for eight months more. When last seen, two years and six months after excision, the splint had been left off about a year. General health fair. Real shortening one inch and a quarter; apparent shortening one inch; the difference being due to slight abduction. Joint firmly ankylosed in good position; no movement independent of pelvis. Walks on sole of foot, preferably with the aid of a stick, but can walk well without it. (Fig. 7.)

CASE 8.—L. A—, aged nine years. Excision of both hip-joints. Disease of the left hip began at eight years of age; no cause assigned. Treated with weight extension and double Thomas's splint before operation. Admitted to hospital one year after onset of disease with an anterior abscess. Limb in good position. Joint excised by anterior incision; head of femur carious, acetabulum affected superficially; head of femur removed; no drainage; temperature below 100° after third day. Primary union in three weeks; no recurrence or secondary operations. Wound finally healed three weeks after excision. Disease of right hip began insidiously while a double Thomas's splint was being worn; it was only noticed a month before excision. Joint excised by anterior incision three months and a half after first excision; head and neck of femur carious and most of head absorbed, acetabulum superficially diseased; head and neck of femur removed and a tubercular focus scraped in trochanter; no drainage. Temperature normal on eighth day. Primary union in three weeks; recurrence in scar six weeks after excision; no further bone disease. One secondary operation. Wound finally healed thirteen weeks after excision. A double Thomas's splint was worn for a considerable time after the operations (exact time not known). When last seen, two years and five months after the first excision, two years and one month after second excision and one year and ten months after final healing of second excision, the patient's general health was good in spite of the fact that she also had had spinal caries for which prolonged treatment had been necessary. Both joints were quite sound. Left limb: Real shortening, estimated, by relation of trochanter to Nélaton's line, two inches; joint allows flexion to 60° and extension to the vertical, also adduction to 45° and slight abduction. Right limb: Real shortening one inch and three-quarters; joint allows flexion to 30° and extension to the vertical, also slight abduction. The patient can walk slowly on the soles of the feet without any support. (Fig. 8.)

CASE 9.—A. C—, aged six years. Disease of right hip

began at four years of age; no cause assigned. Previously treated with Thomas's splint. Admitted to hospital two years and a half after onset of disease with an anterior abscess. This was opened and drained thirteen months before excision. As the sinus did not heal, the joint was excised by anterior incision. Head of femur nearly destroyed, acetabulum superficially diseased; remains of head and part of neck of femur and a sequestrum removed.; drained with tube; temperature never above 101.2°; wound healed by primary union except at tube track. Three secondary operations, three, four and six months after excision. Further bone disease at the first of these only. Wound finally healed eight months after excision. A Thomas's splint was worn for about one year and eight months. When last seen, two years and five months after excision, or one year and nine months after final healing, splint had been left off about nine months. The boy had not gained much flesh, but his general health was good. Joint firmly ankylosed at an angle of 15° flexion; real shortening one inch and a half, apparent shortening one inch and a half. Walking good on sole of foot without support. An interesting point in connexion with this case is the fact that signs of phthisis appeared at the right apex nine months after final healing,

FIG. 7.

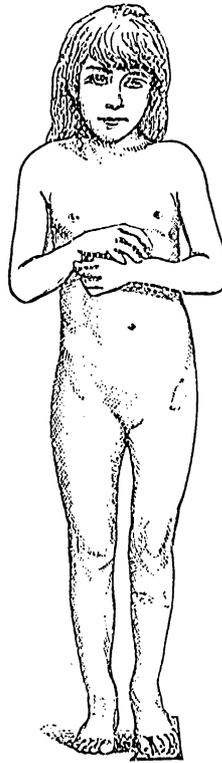

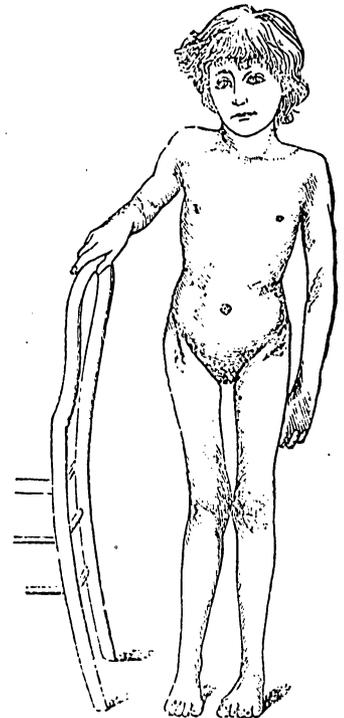

FIG. 8.

but when last seen (nine months after leaving off splint) no sign of phthisis was detected. (Fig. 9.)

CASE 10.—G. P—, aged five years. Disease of right hip began at five years of age, after a fall. A Thomas's splint was worn for some time before operation. Admitted to hospital five months after onset of disease with abscess in front of joint; limb flexed and everted; joint excised by anterior incision; head of femur diseased, acetabulum superficially affected; head of femur removed. Drained for four weeks; temperature never above 101.2°; wound healed by primary union except at drainage tract; finally healed five weeks after excision; no recurrence; no secondary operations. A Thomas's splint was worn for thirteen months after excision. When last seen, two years after excision, or one year and eleven months after final healing, splint had been left off eleven months. General health very good. Joint sound and fixed by firm fibrous union at an angle of 20°; real shortening one inch and three-quarters, apparent shortening one inch and a half. Walking good on toes without support. (Fig. 10.)

CASE 11.—C. N—, aged eight years. Disease of right hip said to have begun when the child was eighteen months

old. Admitted six years and a half (?) after onset of disease with a large abscess over right buttock and a discharging sinus over trochanter; limb was shortened one inch, flexed and adducted; joint excised by posterior incision; head and neck of femur destroyed; trochanter and acetabulum extensively diseased; trochanter and remains of neck removed; drained with tube; wound did not heal. Five secondary operations one, three, four, five, and twelve months after excision; at the second of these the joint was reopened from behind and more of trochanter sawn off. The other operations consisted in the scraping of sinuses and treatment of

FIG. 9.

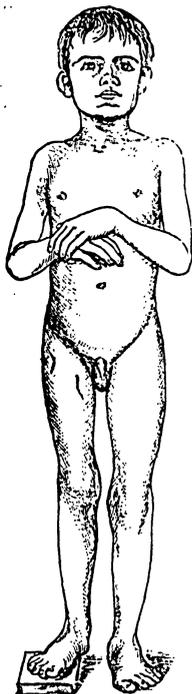

FIG. 10.

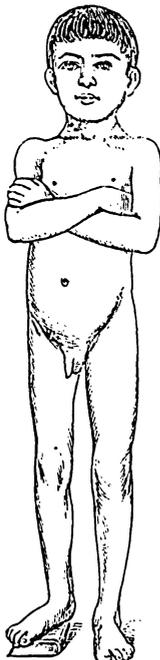

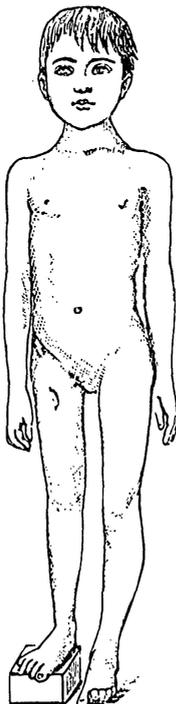

FIG. 11.

fresh abscesses. Wound finally healed thirteen months after excision. Temperature irregular all through till last operation. Splint worn for one year and three months after operation. When last seen, one year and eleven months after excision or ten months after final healing, splint had been left off eight months. General health good. Joint sound; actual shortening three inches and a half, apparent shortening two inches; difference due to abduction. Limb can be flexed to 30° and extended to vertical. Walking good on toes without support. (Fig. 11.)

(To be continued.)

**NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.**—This institution satisfactorily maintains its benevolent activity and usefulness. The new wing is found well suited to the important uses to which it is put. The receipts for the past year were £15,539 0s. 9d., the largest since the hospital has been rebuilt. The amount received for general purposes was sufficient to meet the expenditure and to leave a small balance, but a debt of £2200, with which the year opened, remained. The board has, however, since the account was prepared, been enabled to discharge the several loans and the institution again stands free from debt.

**SOCIETY FOR THE RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.**—A quarterly court of directors was held on Wednesday, July 13th. Sir James Paget, President, was in the chair. Four new members were elected. The deaths of two widows receiving grants were reported. It was resolved to distribute on the 20th the sum of £1296 among the fifty-eight widows and eighteen orphans now in receipt of grants. No fresh applications for assistance were read. The expenses of the quarter amounted to £51 11s.

## PERFORATION OF THE INTESTINE IN PHTHISIS.

By W. SOLTAU FENWICK, M.D. LOND., M.R.C.P.,  
PHYSICIAN TO OUT-PATIENTS TO THE EVELINA HOSPITAL FOR SICK CHILDREN,

AND

P. R. DODWELL, M.B. LOND.,  
ASSISTANT RESIDENT MEDICAL OFFICER, HOSPITAL FOR CONSUMPTION,  
BROMPTON.

(Concluded from p. 186.)

We will now turn to the consideration of the second result of perforation of the intestine by a tuberculous ulcer—namely, the formation of a chronic abscess having a direct communication with the bowel. Fæcal abscess may arise during the course of chronic phthisis under two separate and distinct conditions. In one a small localised collection of pus may form in the abdominal cavity as the result of a previous attack of peritonitis, and bursting through the wall of the intestine give rise to fæcal extravasation. The second variety results directly from perforation of a tuberculous ulcer of the bowel, and it is with this condition that the present paper is alone concerned. Fæcal abscess having its origin in tuberculous disease of the intestine is but rarely met with, for among 122 instances of this affection collected by Dr. Samuel Fenwick<sup>1</sup> only 10 were due to the perforation of a tuberculous ulcer. Among 2000 consecutive necropsies on phthisis performed at the Brompton Hospital we have only been able to discover 10 instances of the disease in question and with considerable difficulty have collected 15 additional cases from various sources, making in all a total of 25. The disease occurs at all periods of life, but perhaps is most frequent between the ages of twenty and thirty. In two cases the patients were less than four years of age, and in one case over sixty. Women appear to be more often the subjects of this affection than men, for of the 25 cases no fewer than 15 were females. The sac of the abscess may be situated either within the cavity of the peritoneum or in the substance of some solid organ. In the first case its walls may be said to be formed by a thickening of the serous membrane and adhesions between the neighbouring organs; while in the second the attachment of the fasciæ and an inflammatory thickening and condensation of the connective tissue constitute an efficient barrier against further diffusion of the purulent material. The cases at our disposal afford two instances in which the abscess-cavity was contained in the substance of a muscle. In one recorded by Piégu<sup>2</sup> a coil of small intestine had become adherent to the right psoas, and a perforating ulcer had given rise to a collection of pus among the muscle bundles. In another instance an abscess in the anterior abdominal wall owed its origin to the adhesion and perforation of a tuberculous ulcer in the ileum. It is interesting to note that in many instances the walls of the sac were found profusely studded with granulations, and in not a few cases an acute tuberculous affection of the peritoneum quickly followed the establishment of the local disease. So long as the sac remains entire the orifice in the bowel continues patent and the pus is feculent; but the abscess is very apt to burrow and discharge, either externally or into some hollow viscus, and when this event occurs the intestinal aperture may become completely closed and, the discharge continuing, may entirely lose its fæcal element.

With regard to the location of the fæcal abscess, it is to be noticed that the large intestine is far oftener the starting-point of the affection than the small, the proportion in our cases being nearly 3 to 1. In 21 instances the post-mortem notes define fairly accurately the position and relations of the abscess. In 10 it was situated in the right iliac fossa, the sac having formed eight times in the subperitoneal tissue and twice within the cavity of the peritoneum. Of the subperitoneal variety 6 were due to perforation of the posterior wall of the cæcum and 2 to perforation of the vermiform appendix, which in these cases was only partially invested by the peritoneum and lay behind the first portion of the large intestine. Both instances of intra-peritoneal abscess in this region originated in perforation of the appendix and

<sup>1</sup> *Obscure Diseases of the Abdomen: Art., Fæcal Abscess.*

<sup>2</sup> *Bulletins de la Société Anatomique, 1837.*

in one case there was a similar lesion in the ileum just above the valve. In five cases the abscess was found to occupy the central regions of the abdomen, in three of these it lay superficially and pressed the intestines backwards, while in the remaining two it was deeply situated among the coils of the small gut and was connected with them by numerous adhesions. The perforations in these cases were found as follows: three were located in the ileum, one in the jejunum and in one both the duodenum and cæcum were simultaneously affected. The pelvic cavity was the seat of an abscess in five cases; in three of these a perforation was found in the small intestine, one in the sigmoid flexure and one in the upper part of the rectum. In only two instances was the faecal abscess situated in the lumbar region, and in both of these the affection occurred on the right side. One originated in perforation of the ascending colon, while the other appeared to have followed faecal extravasation from the vermiform appendix. In twelve cases the abscess burst during life, and it is important to notice that in only one instance did the sac rupture into the cavity of the peritoneum. Three times an abdominal abscess made its way through the umbilicus, feculent matter mixed with pus being discharged continuously through the wound. In four cases an iliac abscess presented at the right groin, and in one the contents of the sac were evacuated by surgical interference. In three instances the abscess burst into some other portion of the intestinal tract; in one a lumbar abscess perforated into the ascending colon; in another an iliac abscess, resulting from disease of the appendix, made its way through the wall of the cæcum, while the third example occurred in the pelvic cavity and the pus found its way into a loop of small intestine.

Attention has already been drawn to the fact that fatal peritonitis may ensue from perforation of a tuberculous ulcer in the intestine without giving rise to any symptoms indicative of the condition, and it is therefore not surprising to find that in the majority of cases the development of a faecal abscess occasioned but little additional disturbance of the general health. Local pain was always complained of, and although this symptom varied in severity in different cases it was invariably increased by pressure and on muscular movement. Nausea and vomiting were noticeable features in nearly every case, sometimes continuing throughout the whole course of the illness, but more often only recurring from time to time. The formation of an abscess appeared to exert no influence upon the diarrhoea which always accompanied the extensive ulceration of the intestinal tract, but in one instance the stools were noticed to contain blood a few days before the discovery of the abdominal tumour. Emaciation proceeded rapidly in all the cases and the tongue presented a dry, furred or fissured appearance. In only one case did the patient suffer from rigors, a fact worthy of particular notice, since in cases of faecal abscess arising from causes other than tuberculous ulceration repeated shiverings are the rule and not the exception. With this single exception the clinical records of the cases fail to show that any definite degree of pyrexia accompanied the formation of the local abscess. Except when rupture of the sac took place, the abscess appears to have exerted but little influence upon the duration of life. In one case an abdominal tumour was discovered by accident a fortnight prior to death, and in the majority of cases life was certainly prolonged for three or four weeks after the presumable occurrence of perforation death finally resulting from exhaustion. From these facts it is obvious that a faecal abscess cannot be looked upon as a complication of chronic phthisis endowed with any symptoms more striking than those of chronic local peritonitis.

In 14 out of the 25 cases the presence of an abdominal tumour attracted notice during the life of the patient. In 9 instances the swelling occupied the right iliac fossa, in 3 the epigastric and umbilical regions, and in 2 the tumours invaded the greater portion of the anterior division of the abdominal cavity. The case with which it could be detected varied according to the relation of the sac to the abdominal wall, the outline being irregular and ill-defined when the abscess was situated deeply among the coils of intestine, but rounded and distinct when it occupied a more superficial position in the neighbourhood of the cæcum. In a few cases the swelling was sufficiently large to produce an obvious effect upon the outline of the abdomen. Owing to the presence of adhesions the tumour was always firmly fixed to the surrounding structures, and hence it not only resisted all attempts to displace it by lateral pressure with the fingers, but also failed to alter its position during forced acts of

respiration. Various statements are made with respect to the consistency of the tumour, some writers describing it as "hard and irregular," others as "soft and smooth," while the term "brawny swelling" is frequently made use of to express the physical characters of the disease when situated in the iliac fossa. In a few instances a certain amount of elasticity could be detected in the tumour, but true fluctuation could seldom be made out satisfactorily. It occasionally happened, especially when the abscess was situated in the iliac fossa, that firm pressure over the swelling produced a gurgling noise. This sign was probably due to the sac containing a mixture of air and fluid, but in some cases it might also have arisen from the presence of a piece of intestine interposed between the anterior surface of the tumour and the hand. The percussion note over a faecal abscess is liable to wide variation. Sometimes the note proves quite dull, and under these circumstances the sac is presumably full of fluid. In other cases the note is found to vary according to the force of the percussion stroke, being hyper-resonant when the finger is lightly struck, but becoming dull and toneless when more forcibly percussed. Such a qualitative change in the percussion note arises in all probability from the composite nature of the contents of the abscess, the tympanic sound being the expression of its gaseous moiety and the dull note that peculiar to the fluid portion. There is, however, one percussion sign of such importance that, when present, it is pathognomonic of faecal abscess—the sudden development of tympanic resonance over a tumour which had previously yielded only a dull note. In such a case the development of gas within the tumour can only have arisen from putrefaction among its original contents or by the direct admission of air or intestinal gas into the cavity of the abscess. In one of our cases it was expressly noticed that when the abscess due to perforation of the duodenum discharged itself through the umbilicus, the appearance of the pus was preceded by an escape of a large quantity of very fetid gas, after which the whole tumour became dull on percussion.

In addition to the foregoing there are one or two physical signs which are more rarely encountered. The outline of the tumour as determined by percussion is sometimes found to vary with the position of the patient and a distinct splash becomes audible when the body is shaken or suddenly moved. In other cases, again, the physical characters of the swelling appear to be influenced to a great extent by the state of the bowels, a sudden attack of diarrhoea often giving rise to a remarkable diminution in the size of the tumour. This latter sign is almost entirely confined to those varieties of faecal abscess which originate in causes other than tuberculous ulceration of the bowel, for in our cases diarrhoea was a constant and not an occasional symptom, and consequently a sudden diminution in the size of the sac was never observed unless rupture had taken place. From these facts it would appear that whenever an abdominal swelling, unattended by special symptoms, presents itself during the latter stages of chronic phthisis, irregular and ill-defined in outline, immovable on deep inspiration or by pressure with the fingers, tympanic on light and dull on deep percussion, with gurgling and pain on pressure, it will almost certainly prove to be a faecal abscess. In certain cases, however, the diagnosis may prove of some difficulty, for not only may the tumour itself be difficult to investigate on account of its deep situation, but the physical signs peculiar to it may be simulated closely by other pathological conditions. It may happen that an abscess arising from perforation of the duodenum, instead of coming forwards as in the case previously alluded to, may remain localised in the immediate neighbourhood of the lesion. In this position the tumour is difficult to detect on account of the rigid condition of the abdominal walls, and the auscultatory phenomena may so closely simulate those of pneumothorax that Leyden has designated the condition "pyo-pneumothorax subphrenicus." In true pneumothorax, however, the whole of one side of the chest is expanded and motionless, while in peri-duodenal abscess the expansion of the thorax due to the tumour is strictly confined to its lower part. In the former case, again, the percussion note is hyper-resonant, the breath sounds either diminished or totally suppressed, tactile fremitus abolished, and the heart driven over towards the opposite side. In the latter condition the diaphragm is pushed upwards and the base of the lung compressed, hence where the breath sounds are deficient the percussion-note is dull and tactile fremitus increased; while the heart may be tilted upwards, but is never laterally displaced. Lastly, if air and fluid coexist in the chest the splashing sounds are

limited to the diseased side, but if gas and liquid are associated in an abscess cavity, the splash and metallic phenomena are distinctly audible all over the abdomen and back.

The left lobe of the liver is frequently enlarged in cases of chronic phthisis, and if previously the seat of hydatid or syphilitic disease the tumour may present some difficulty for diagnosis. From faecal abscess, however, such a condition is easily distinguished by the absence of pain on palpation, its slow growth and more definite outline, its free movement on inspiration and by the fact that percussion produces a dull note under all circumstances.

If the tumour be situated in the right iliac fossa it may be confounded either with a caecum thickened by tuberculous disease of its mucous membrane or with a mass of caseous glands located behind the first portion of the large intestine. In each case a gurgle may be produced by pressure and the percussion note vary with the force of the stroke. A thickened caecum, however, usually forms a tumour less distinct in outline than a faecal abscess in this situation, is less painful on pressure and exhibits little tendency to increase in size. A bundle of caseous glands may easily be recognised from the fact that the tumour it gives rise to is much harder and more irregular in outline and less painful on pressure than a faecal abscess, while other enlarged glands can often be detected in the immediate vicinity or elsewhere in the abdominal cavity. It must be remembered, however, that if suppuration should occur in connexion with the tuberculous mass, the pus may eventually burst through the caecum and give rise to a true faecal abscess. In the cavity of the pelvis the existence of the disease can seldom be determined during life. Faecal abscess connected with the colon may be mistaken for a tumour arising from the kidney. In the latter case the urine generally contains albumen, blood or pus, and the symptoms present point more strongly to a tuberculous affection of the kidney than to the exceedingly rare association of a local abscess with perforation of the ascending colon.

In conclusion, we will as briefly as possible draw attention to a few of the less important local results of perforation of the bowel by a tuberculous ulcer. When extensive adhesion exists between the coils of the gut, a perforating ulcer, after destroying the whole thickness of the bowel, may find itself confronted by the serous surface of another coil and proceed to eat its way through the tissue opposed to it until it has opened up the cavity of the bowel. In this manner the intestines may be completely honeycombed and the contents of the intestinal canal no longer follow a definite route but pass at random from one portion of the intestine to another. Thus Rindfleisch<sup>3</sup> states that these fistulous openings in the wall of the gut may exceed in diameter that of the intestine itself, and instances one case where he found five such irregular means of communication existing between different parts of the intestinal canal. In other cases fistulae may originate by an intermediate process of abscess formation. A slight amount of leakage having taken place through the base of an ulcer, inflammation and suppuration are promptly excited in the vicinity, and the abscess thus formed by burrowing in different directions may effect a communication with another of a similar nature, or even find its way through the wall of a contiguous coil. Should any obstruction exist in the course of the intestine situated between these two points the abscess track will be appropriated by the intestinal contents as an easier means of transit, and a permanent fistula be established. Thus in one of our cases a perforation existed in the lower end of the ileum just above an obstructed ileo-caecal valve, and the abscess had communicated with an aperture in the vermiform appendix and allowed the contents of the small intestine to find their way into the caecum. In another instance an intra-peritoneal fistula was found to connect a perforation in a diverticulum from the ileum eighteen inches above the valve with the dilated cavity of the appendix caeci, and here again the valve was much obstructed. Rintel<sup>4</sup> records a case in which an abscess resulting from perforation of the duodenum had burrowed downwards and eventually established a communication with the caecum. After death it was evident from the empty and contracted state of the jejunum and ileum that the whole of the gastric contents had been accustomed to circulate along the false canal instead of following the natural but more circuitous

route. These abnormal conditions, however, seldom give rise to any definite symptoms or physical signs, and are consequently of greater interest to the pathologist than the physician.

## NOTES ON OCEAN TRAVEL FOR HEALTH AND DISEASE.

By JOHN V. SHOEMAKER, A.M., M.D.,  
PHILADELPHIA, U.S.A.

LIFE at the end of the nineteenth century is so eager and full of struggle, competition is so keen, the reward of successful effort so great, that most of us in every station neglect those precautions and habits upon which continued health chiefly depends. Prolonged and anxious intellectual labour, irregular hours, warm and ill-ventilated rooms, insufficient sleep and exercise, strain the nervous system, beget indigestion and innumerable physical evils. The physiological and prophylactic remedies of out-door exercise, rest, diet, rational amusement, which do so much to keep us in health, are not so generally utilised as their inestimable value deserves. Accordingly we approach the summer season jaded, worn, with nerves unstrung, appetite feeble, digestion faulty, sleep restless and insufficient. Rest is urgently demanded; the brain needs to lie fallow for a time that it may recuperate after its strenuous energy. Among the many means to which we may resort for restoration of physical and intellectual force I would unhesitatingly assign a high, perhaps the highest, place to ocean travel. To leave our accustomed haunts and treadmill round of duty for a while, to exchange the tasks which have wearied us and the places with which we are familiar for new scenes and occupations is highly beneficial. To cast off for a time the load of labour and responsibility which we carry, to feel ourselves for a space at liberty, is a wonderful relief. Often we do not realise how heavy has been our burden until it is temporarily removed. Rest and travel by land and sea are sovereign agencies in recruiting exhausted strength. A tranquil country life will afford repose, but its monotony will often weary the spirit habituated to variety and excitement. Summer travel by rail is not restful. Our seaside resorts, beneficial though they doubtless are, afford too much opportunity for social dissipation, so that their good effects are to a great extent lost. They are open to the objection, moreover, that the father of the family can so easily "run up to town" when what he needs is to escape the city's heat and confusion. No remedy is a panacea. The most useful agencies can be abused. Change and recreation are desirable. To exchange the counting-house or the office for the smoking room of an ocean steamer, to smoke, drink and play cards while crossing the Atlantic is to wilfully throw away the advantages which may be obtained from the journey. Life at sea is sufficiently full of incident to avoid the reproach of dullness. One meets with old friends or forms new acquaintances and a pleasant, leisurely intercourse permits the days to glide by without weariness. The sea air, always in circulation and charged with ozone, invigorates the exhausted system. Movement is not restrained. We feel the ship beneath us forging its way through the water, the deck affords us an ample promenade, the heaving surface of the ocean a picture full of charm. The pure salt breeze fans our cheeks, the porpoise or the shark claims a share of our attention, and as we traverse the ocean highway we meet other steamers sending up their clouds of smoke or sailing vessels with canvas spread to catch the wind.

The panorama of the heavens is a spectacle of beauty, grandeur and awe. Who can describe or who can depict the glories of the rising or the setting sun? On the eastern horizon the grey light of dawn becomes brighter, and above the surface of the deep the king of day arises. A rosy glow lights up the sky as the sun starts upon his daily race. At eventide the brilliant spectacle is repeated as the orb sinks below the line. What a flame of colour shines in the west as the sun majestically descends! The vivid crimson reflected from cloud to cloud gradually fades to rose, to pink, to purple as the light of day vanishes and at last the pageant has ended. Then, when twilight has deepened into dark, the stars peep out and the dark expanse above us is studded with innumerable sparkling lights upon which we gaze with admiration and by which our

<sup>3</sup> Pathological Anatomy, vol. i., p. 440.

<sup>4</sup> Berl. Klin. Woch., 1867, p. 332.

captain calmly shapes his course across the trackless waste of waters. Anon the moon, fair queen of night, arises and as she takes her place among the glittering constellations the sublimity of the night scene culminates. Whether crescent or full, alike beautiful, her silvery beams falling upon the water mark a track of light across the sea. The sweet light which fills the air seems to the fancy more mystic and solemn than that of day. Thus, day after day, wind and wave, sun, moon and stars are our companions. Their sweet influences sink unconsciously into our minds and work a subtle change throughout the system. It is good for us to be led away from our toils and ambition to commune with Nature. On land the face of Nature shows more variety, but is seldom so imposing and so attractive in its grand, stern features as upon the sea. The pure, equable and invigorating ocean climate, the pleasant idleness and agreeable companions of our journey, the grand natural scenes spread out before our eyes, form a totality of influence capable of rejuvenating weary minds and bodies and restoring us with renewed power to the scenes of our wonted activities.

But to this alluring picture of rest and recreation there is a reverse side. Few altogether escape sea-sickness upon their first voyage, many never entirely lose their susceptibility to attack. In the majority of instances the sick person recovers after a few days have passed, and the latter portion of the voyage is both pleasant and beneficial. Indeed, so thorough has been the evacuation of the system that when recovery is finally established the appetite is extraordinarily vigorous. The depression which the sickness had caused gives way to an exaltation of mind and body to which one has long been a stranger. Exceptional individuals are indeed met with to whom an ocean voyage is always an affliction and who are compelled to lie in their berths from one shore to the other. To such ocean travel can scarcely be recommended, though if free from organic disease they not infrequently gain strength rapidly as soon as they have landed. The symptoms of sea-sickness are so well known as to require no description. Its mode of genesis is as yet imperfectly understood, though it probably depends upon disturbance of the central nervous system by the alterations or shocks of the sense of equilibrium produced by the rolling or pitching of the vessel. That it is not chiefly due, as has been surmised, to the effect upon the visual centre is proved by the fact that the blind are not exempt from sea-sickness. An experience of twelve years, during which I have spent many of my holidays upon the sea, has convinced me that *mal de mer* can only be avoided and controlled by the exercise of a strong will in conjunction with a fairly healthy condition of the nervous and glandular systems. It is of advantage some days prior to sailing that the alimentary canal should be thoroughly cleansed by the operation of a saline or mercurial cathartic. In the absence of or after recovery from sea-sickness the sanitary effects of a sea voyage are very decided. The result is brought about by a combination of physical and psychological influences which have been already glanced at in the foregoing remarks. First in the category is the ocean climate. Sea air stimulates the appetite, improves digestion, assimilation, secretion and excretion. The glandular follicles and organs of the alimentary system are awakened to a high state of functional activity. Relaxed muscular tissue becomes firm, the heart is invigorated, the circulation is carried on more actively, respiration is deepened, the pure air inhaled promotes a quickened oxidation and tissue change, the skin grows soft and blooming, the tone of the nervous system is raised and a cheerful state of mind induced. The traveller gains flesh and strength, sleep is sound, lassitude vanishes and irritable nerves become firm. A portion of this improvement is doubtless to be attributed to the companionship and amusements on board and to the daily and nightly spectacles of sea and sky.

I have by implication alluded chiefly to the summer voyage by steamer to Europe simply because it is that with which I, in common with many of my countrymen, am most familiar. Our own seaboard is, however, so extensive that innumerable short sea trips can be taken during favourable seasons upon either the Atlantic or Pacific coast. Those dwelling in the interior have, in the great lakes, a serviceable substitute for an ocean voyage. The atmosphere of the lakes is hardly equal in tonic properties to that of salt water, though it is certainly pure, and the voyage from Buffalo to Duluth possesses peculiar interest. In the summer the inhabitant of one of our Eastern cities can avail himself of the steamship lines which will convey him along the New England coast, while

in the winter he can travel to the south. On the Pacific one can cross to Japan or China, or make the very interesting and beneficial excursion to Puget's Sound, and thence along the coast to Alaska. Under certain circumstances the old-fashioned sailing vessel offers superior advantages to any steamer. If there is reason to believe that the health will be improved by an ocean voyage, the slower progress of the sailing vessel allows more time for the work of recuperation to proceed. On the other hand, the lack of genial company, the coarser fare and accommodation to be found upon sailing vessels will in many cases neutralise their advantages. The journey across the Atlantic by the most direct routes has gradually been so shortened that hardly time enough is allowed on shipboard, especially if half that period is occupied by an attack of sea-sickness. This objection can be partially met, however, by choosing one of the less direct routes. There are many to whom it is of more value to spend a few additional days upon the ocean than to rush at the highest attainable speed from New York to London, Paris or Berlin. Besides those who every summer seek Europe for commercial purposes or in pursuit of pleasure there is a small army who go in order to re-establish their health. At the head of the list may be placed the overworked business or professional man who for nine months has toiled almost without cessation. The most hurried meals, the scanty nights' rest have robbed him of flesh and freshness, his appetite has failed, his digestion is bad, his bowels constipated or irregular, his head often aches or is the seat of an indescribable feeling worse than an ache, his mind is dull, his nerves are unsteady and temper irritable, and his work has become a burden. He determines or is bidden to tear himself away, engages his passage and is a changed man before he reaches the end of his voyage. He can again look on the bright side of life, can laugh and be amused, can enjoy his meals and sleep all night. He lands, visits spots of historic interest, pleases himself perhaps in visiting the home of his ancestors and returns to this country vastly benefited by two ocean voyages and a sojourn in another land. How often have I witnessed such transformations and, indeed, experienced it in my own person.

Next reference may be made to the unhappy victim of dyspepsia. "The accursed hag Dyspepsia," as Carlyle says, "had got me bitted and bridled, and was ever striving to make my living day a thing of ghastly nightmares. I resisted what I could, never did yield or surrender to her, but she kept my heart right heavy, my battle being sore and hopeless." Few have the force of intellect and will that distinguished Thomas Carlyle, and what wonder that despondency, hypochondria, melancholia, and sometimes suicidal mania, may follow in the train of chronic and aggravated indigestion. Again, though the will can do much, it cannot counteract the effect of chemical poisons engendered by faulty processes within the alimentary canal. Palpitation, asthma, eczema, urticaria, lithemia and other troubles may be the outcome of the same cause. Many of these consequences may be averted and the condition of the patient vastly ameliorated by an ocean voyage. Sea-sickness to such an individual is not an unmixed evil. The alimentary canal is cleansed perforce, the man begins anew, and if he be free from grave organic disease of stomach or liver the improvement may be permanent. The constipation which troubles so many without seriously undermining the general health, yet which produces a muddy complexion, engenders headache and dulls the mind, generally yields to the improved nutritive conditions caused by breathing sea air. The secretions are augmented and peristalsis excited. It is well known that many forms of cutaneous disease are excited either directly or indirectly by chronic indigestion. The toxic products of imperfect metabolism thrown into the circulation act, in some cases, as specific poisons to the skin, its appendages, nerve-supply, vascular, or absorbent system. To remove the cause has from time to time been recognised as the first step in therapeutics, and in consonance with this axiom, when a few days' travel upon the ocean has ameliorated the indigestion, acne, seborrhœa, eczema, psoriasis, and paræsthesia are often more speedily and rapidly benefited by a sea voyage than by the most competent and elaborate advice and use of the most approved remedies while the patient remains at home. In addition to the systemic influence the skin is directly improved by the moist atmosphere of the ocean. Chronic gastro-enteritis is relieved by a trip across the water. The vascular stasis of stomach and bowel is removed and the local circulation quickened, the vaso-motor tone is raised, the inflammatory products are expelled and the anatomical

condition of the mucous membrane is materially changed. The muscular fibres are invigorated, secretion is more efficiently performed and the patient reaches his destination in a much better condition than when he began his journey.

Salt water has long enjoyed a popular reputation of conferring immunity against the effects of exposure to cold. Fishermen and boatmen along the coast as well as sailors in mid-ocean pursue their laborious avocations in dripping garments without fear of "taking cold." How much of this protection is due to the salt contained in the water and air, and how much to the natural resistant power of a hardy organism, I shall not attempt to determine. Whether fishermen off the coast are less liable to attacks of catarrh of the respiratory passages than men who follow the same calling in fresh water I am unable to say, yet the general belief of seafaring men, founded upon abundant experience, must contain an element of truth. At all events, signal amelioration often attends a journey by sea in the case of bronchial and pulmonary disease. In chronic bronchitis inflammatory action is lessened, expectoration and cough are diminished, respiration becomes more free and sleep more sound. Vesicular emphysema is relieved by the favourable impression made upon the attendant bronchitis, by the tonic effect upon the heart and the improvement in digestion. In many cases of spasmodic asthma the patient, while at sea, is spared his distressing paroxysms. Attacks of hay asthma may be escaped by a sea voyage. A strong illustration of the neurotic element in asthma is the fact that those sufferers whose home is in the interior are more apt to be benefited by sea air than those who dwell near the coast. A voyage is a sovereign remedy for insomnia. When this habit is strictly dependent upon nervous strain or obstinate indigestion it vanishes as the conditions which gave rise to it improve. Many people of middle age, however, without any apparently decided failure of general health are not able to readily fall asleep. They may feel drowsy before preparing for bed, but the act of undressing arouses them and by the time their heads touch the pillow they are wide awake. This wakefulness continues for some hours, the patient rolls in his bed and adopts various devices in order to woo sleep, but in vain. The mind is singularly active when one wishes rest, unpleasant subjects of thought arise like magic and in time the patient dreads retiring for the night. This very apprehension intensifies the difficulty and thus the case progresses, and fortunate is the man who resists a strong temptation to have recourse to narcotics. The sea exerts a wonderful power in this condition. The ocean atmosphere possesses decided hypnotic virtue and "Nature's sweet restorer, balmy sleep" closes the eyes of the thankful traveller. An ocean voyage mitigates or suspends the pain of neuralgia. Free from torment, a hearty appetite, an abundant consumption of food, quickened oxidation and sanguification re-establish the nutrition of nervous tissue. The affected cords restored to health cease to be sources of agony. A remarkable happy effect is often produced in hemicrania. I have known patients whose pangs were periodical and excruciating to experience entire freedom during the passage, to suffer from no relapse for months afterwards, and indeed in some instances the malady has never since returned. A very pleasing effect is often produced in melancholia. The settled gloom is gradually dispelled. The poor sufferer little by little awakens to an interest in life, ceases to meditate continually upon his woes, listens to cheerful conversation and no longer avoids his fellows. The hypochondriac, improved in physical health, forgets his morbid fears. The hysterical girl, impressed by the majesty of Nature, with nerve centres fortified by the multifarious influences of her unaccustomed surroundings, is led to forget her own personality, and ceases, for a time at least, to be a source of trouble or annoyance to her relatives. A more lasting effect is produced upon neurasthenia. New and richer blood feeds brain and spinal cord, languor disappears, and the patient returns home with a new lease of life. Choreic children are often vastly improved, or even cured, by a sea-voyage. Jerking and irregular movements gradually decrease, sleep becomes uninterrupted and normal, coördination at last results. Epilepsy also is often benefited. The spasms are mitigated in severity and recur at longer intervals. Ocean travel is of conspicuous advantage to the subjects of anæmia and chlorosis. It is unnecessary to repeat what has been already said concerning the freshened activity of the blood-forming organs. Suffice it to say that the capricious and perverted appetite becomes keen and normal, pallor and discolouration rapidly vanish, the lips and mucous membranes

acquire a rosy hue, muscular strength augments, and, in brief, the patient is soon cured. A sea voyage may very appropriately be recommended to one who has just recovered from an attack of purpura, particularly of the hæmorrhagic variety. Local disease of the skin remotely connected with chlorosis is benefited by removal of its cause. As regards the menstrual function, the usual primary effect of crossing the ocean is suppression for a few periods, but the ultimate influence is beneficial. Dysmenorrhœa is sometimes, and ovarian neuralgia generally, relieved.

(To be concluded.)

## A NATIONAL DANGER: LEAD POISONING FROM SERVICE PIPES.<sup>1</sup>

By ALFRED SWANN, M.D.,

MEDICAL OFFICER OF HEALTH FOR BATLEY; SURGEON TO THE BATLEY AND DISTRICT HOSPITAL.

THIRTEEN years have now passed since I first drew attention to the great danger of supplying water for drinking and dietetic purposes through leaden service pipes. During that period a great deal has been said and written upon this subject, but as far as I can gather the really fearful danger existing from this cause has either been ignored or only partially recognised. The general opinion seems to have been that the results of drinking water very slightly contaminated by lead were rather inconvenient than dangerous, and my object in writing the present paper is to show that a serious national danger exists, and I do not think after perusing these lines anyone can doubt my deductions. Ocular demonstration is a very important thing in a case like the present and a very simple means is at everyone's disposal for ascertaining the presence of lead in water. A solution of one grain of bichromate of potash to the ounce of distilled water furnishes everybody with a test capable of discovering 1 part of lead in 500,000 parts of water and I would recommend every medical man residing in districts suspected of lead poisoning to make use of the foregoing. My method has been as follows: To one gallon of water free from lead I have added one grain of lead acetate; to fifteen drachms of this solution one drachm of the bichromate solution is added. This gives the precipitate obtained by one grain of acetate of lead to the gallon of water. The original acetate of lead solution I dilute by halves: thus, 1 gr.,  $\frac{1}{2}$  gr.,  $\frac{1}{4}$  gr.,  $\frac{1}{8}$  gr.,  $\frac{1}{16}$  gr.,  $\frac{1}{32}$  gr.,  $\frac{1}{64}$  gr., and to each I add the same quantity of the test solution. This gives a series of graduated colour tests which can be used for comparison with any sample of water brought for analysis.

The last ten samples of water tested by me in the foregoing manner give the following results:—

Case	1.	2.	3.	4.	5.	6.	7.	8.	9.	10.
Reaction equal to	"	"	"	"	"	"	"	"	"	"
of a grain of lead acetate to the gallon.	"	"	"	"	1 grain of	$\frac{1}{2}$ of a grain of	1 grain of	$\frac{1}{2}$ a grain of	1 grain of	$\frac{1}{2}$ a grain of
"	"	"	"	"	"	"	"	"	"	"

The foregoing cases were taken haphazard in my daily practice between June 9th and June 27th this year and represent a class of cases such as I have been treating without intermission for the past thirteen years.

CASE 1.—Female about sixty years of age, in easy circumstances. Has suffered for many years and was told by a medical man some years ago that she had cancer of the stomach. Present condition: Never free from abdominal pain, which increases frequently to agonising colic; constipation; profound anæmia. Other members of the same household suffer from colic and digestive disturbances which disappear when they leave home.

CASE 2.—Female aged about thirty-four. Colic; constipation; anæmia; frequent abortions.

CASE 3.—Male aged about forty. Colic; constipation; lumbago; rheumatic pains.

CASE 4.—Female aged fifty-five. Progressive motor and sensory paralysis of legs; lumbar pain; constipation; colic occasionally.

<sup>1</sup> For complete and exhaustive information on this subject I would refer to "Études sur les Eaux Potables de le Plomb," par A. Hamon, Paris, 1884, to whom I am indebted for much valuable assistance.

CASE 5.—Female aged twenty-five. Menstrual irregularities, sometimes profuse; constipation; colic; abortions.

CASE 6.—Female aged seventeen. Distressing colic; constipation; menstrual irregularities; profound anæmia.

CASE 7.—Female aged thirty-eight. Profound anæmia; constipation; colic; menstrual irregularities.

CASE 8.—Male aged ten. Paroxysmal colic; occasional diarrhoea; choroid movements about eyes and hands; anæmia.

CASE 9.—Female aged thirty-one. Constipation; colic; anæmia; faintings; confusion of ideas; occasional loss of speech and sensation; mental condition gradually deteriorating.<sup>2</sup>

CASE 10.—Female aged fifty-eight. Anæmia; constipation; lumbago; gout.

To the foregoing cases I would add the following:—

S. B—, aged about forty. Agonising colic; blue line round teeth. Would not believe it was lead. A magnificent specimen of muscular humanity. For years went from bad to worse; developed albuminuria. Passed from under my care, but shortly after 'died of "apoplexy." Young son living in same house about ten years old. Completely paralysed (general paralysis); blue line round gums.

S. S—, aged thirty-five. Joiner. Suddenly went blind in right eye. Retinal hæmorrhage; blue line round gums; constipation; occasional colic.

I could multiply cases *ad infinitum*, but the foregoing are enough for my purpose. To justify the heading of this paper,<sup>3</sup> I must state that Mr. Walker of Heckmondwike, the inventor of the "health" iron tin-lined service pipe, has kindly allowed me access to his collection of sample specimens of water from the following districts. He has for some time adopted the following plan. After obtaining a sample of water from a given district he places in it a piece of polished lead and leaves it there. In the course of a very few days, sometimes hours, a precipitate begins to form and very soon the water becomes milky, and there really in many cases seems to be no limit to its solvent action under these conditions. He has informed me that he will be glad to show these specimens to anyone interested in the subject.

The following is a list of the waters of which Mr. Walker has specimens and which show a great power of dissolving lead, and I cannot do better than use his own words, which are as follows: "Distilled water acts very vigorously and throws down plenty of lead salts in a short time. Glasgow water acts still more vigorously and deposits more lead salts. Wakefield water acts very strongly on lead, making plenty of lead salts in a short time. Leeds water acts sometimes strongly and at other times very little. Morley water, which is from Leeds, we find acts strongly, but it also varies. Huddersfield, Mirfield, Dewsbury and Heckmondwike, Manchester, Oldham, Blackpool and Halifax act vigorously, all of them depositing lead salts, some acting rather more quickly than others. Batley, Ecclehill, Birstall, Gomersal, Pudsey, North Bierley act very vigorously. Barnsley, Clifton, Rastrick and Brighouse, all these have an affinity for lead, though not so strong as the others. Newcastle-on-Tyne water takes the lead into solution, but does not throw down or deposit lead salts; but having had only one sample of this water I am not prepared to speak with certainty of it. Liskeard water acts very vigorously."<sup>4</sup>

This list is quite sufficient justification for the heading of this paper and the urgency of the subject is increased by the fact that at the present time local authorities seem to be making positively no efforts to check the use of leaden service piping. When we realise that half a century before the Christian era Vitruvius condemned lead service pipes and 130 years after that time Galen did the same thing, it is a puzzle to my mind to know how it is that the use of such a poisonous means of conveying water should ever have become general.

The amount of physical suffering, mental<sup>4</sup> degeneration and death brought about by lead poisoning, coupled with the fact that children begotten by poisoned parents are puny, rickety and ill developed, both mentally and physically, makes one feel that the Emperor<sup>5</sup> of olden days who made the use of lead pipes a capital offence was gifted with a prescience and wisdom unknown in our enlightened age.

Batley.

<sup>2</sup> Since writing above this patient has had an attack of right hemiplegia and loss of speech.

## PARALDEHYDE: HYPNOTIC AND DIURETIC.

By J. COCKBURN SYSON, M.B. GLAS. &c.

HAVING frequently had occasion within the last six months to use paraldehyde as a hypnotic it may be of interest to record one or two observations made during the administration of the drug. In a case of senile arterial degeneration with considerable mental depression, restlessness, marked insomnia and where there existed a double aortic murmur, with a mitral regurgitant and enlarged left ventricle, I was induced to try the drug after unsatisfactory results from sulphonal, urethane, chloral &c. At first forty minims in peppermint water were given and this was followed by a state of comparative restfulness, though sleep was not induced. Two hours later, the pulse being unchanged, thirty minims more of the drug were administered and within half an hour the patient dropped quietly to sleep, which lasted, more or less, for four hours. It was described as being more refreshing than that produced by sulphonal and not accompanied by the same depression and uncomfortable sweating. The offensive odour of the drug however was objected to and this could be detected in the patient's breath during the next forty-eight hours. Two nights later the same doses were given, but these failing to produce the desired effect a third dose of fifty minims was allowed three hours after the second. After this third dose it was noticed that, though the patient was evidently asleep, there was considerable muscular twitching and shifting about in the bed. At short intervals he would sit up (his eyes being closed the while) and make incoherent remarks, but when told to go to sleep would lie down again and remain perfectly quiet during periods of ten or fifteen minutes. This lasted for three hours, after which there was still more or less drowsiness, though the patient did not again go to sleep. The pulse was not in any way weakened, but during the ensuing twenty-four hours there was marked muscular weakness and polyuria.

On the third night after the last administration paraldehyde was again given, beginning this time with a dose of sixty minims. In twenty minutes the patient felt drowsy and was asked to lie down and go to sleep. At the end of an hour, being still awake, sixty minims more of the drug were administered, but only short snatches of sleep followed and there was, as on former occasions, considerable muscular twitching and rambling talk. On the day following it was again remarked that the patient voided an excessive quantity of urine. There was no diarrhoea and the appetite was not interfered with. The muscular weakness was again very marked and during nearly twelve hours there was more or less stupor and drowsiness. Having failed to induce a fair amount of sleep with drachm doses, and feeling disinclined to push the drug further, I was forced reluctantly to fall back upon morphia.

In about three weeks from the last administration of paraldehyde cardiac compensation began to fail and there was considerable dropsy about the ankles and half-way up the legs. Remembering the diuretic action exhibited by paraldehyde, I was induced to again have resort to the drug with the hope of getting rid of the dropsy. Ninety minims were given at 10 p.m. Within twenty minutes the patient was asleep, though his rest was disturbed by the muscular twitchings and restless movements already mentioned. At 12 midnight he had become quieter, but was not asleep. The pulse being satisfactory and not apparently affected by the hypnotic, another drachm was administered and further snatches of sleep were induced. Altogether, with two drachms and a half of the drug something like three hours' sleep were procured, and followed by several hours of quiet and drowsiness. During the following day the weakness and unsteadiness of gait were very marked, the patient walking with difficulty and having to steady himself by catching on to objects in his room. But the most striking result was the complete disappearance within twelve hours of the dropsy, which had persisted more or less for a week, and the accompanying presence of polyuria. On a subsequent occasion as much as 120 minims of the drug were given in one dose, followed in two hours by 90 minims, but the excitement and spasmodic muscular movements were so great as to make me think the cure worse than the disease, and so for the

nonce the drug was discontinued. Three weeks had again elapsed since paraldehyde was last given, and, being unable to use sulphonal owing to the extreme after-depression and misery, I determined to again give paraldehyde a trial, but this time in repeated small doses. Beginning at 6 P.M., 30 minims were given, and this was followed at 7 P.M., 8 P.M., and 9 P.M. by 20 minim doses. After the second dose the patient was restful, lying quiet for half an hour though not sleeping. After the third dose the excitement and restlessness began to appear, and when the fourth had been given these were so great that the patient's friends were unwilling to have the drug pushed further. This state of matters lasted for an hour, after which the patient lay quiet for nearly four hours, during which time he had occasional and short intervals of sleep. This result I considered unsatisfactory and did not again use paraldehyde in this case. It is to be noted that at no time during the use of the drug, even when given in such considerable quantity, was there any diarrhoea—an after effect mentioned in the Year Book of Treatment for 1892 (p. 88) as sometimes occurring. From its non-depressing effects upon the heart's action, and since it seems to have diuretic properties, paraldehyde may become a useful hypnotic in cardiac cases where there is dropsy. Though I was induced to give up its use in this particular case I have not lost faith in the drug. The insomnia here was most intractable, and of all the hypnotics used, with the exception perhaps of opium, paraldehyde on the whole gave the most satisfactory results, and can be used where it would be decidedly risky to push the older drug. To sum up, then, it seems to me that, so far as my limited experience of the drug goes, paraldehyde may be looked to as a fairly reliable and safe hypnotic, that its administration is followed by a well-marked stage of excitement, that it does not depress the heart's action, does not interfere with the appetite or digestion, possesses probably diuretic properties and induces a sleep which is described as "refreshing."

Beith, N.B.

## A DEMONSTRATION OF ACUTE PNEUMONIA, ITS FORMS AND ISSUES.<sup>1</sup>

BY A. G. AULD, M.D. GLASG.,  
GLASGOW WESTERN INFIRMARY PATHOLOGICAL LABORATORY.

ACUTE pneumonia in its pathological aspect is commonly regarded as the summation of a more or less definite and constant series of changes resulting from generalised inflammation in the lung. Thus viewed it is held to be made up of four stages, those namely of engorgement, of red hepatisation, of grey hepatisation, and of resolution. Here is a standard to which the disease is continually being referred, a mould into which it is constantly being cast, but the wider our study of pathology the more liberal becomes our conception of the scope of morbid processes. The stereotyped image gets dashed to pieces as disease manifests itself in its protean aspects. To this broad principle pneumonia forms no exception, its histological features are no less diverse and inconstant than are its issues.

Clinicians well know the various courses which this affection may pursue. Sometimes hepatisation declares itself only to vanish quickly and resolution is promptly effected; in other instances it proceeds wave-like over the organ, closely followed, it may be, by the symptoms of its breakdown. Or it may exhibit a faltering, a persistent, or even a recurrent character. And although the duration of the disease is by no means the measure of its fatality, the latter element will not infrequently yield its readiest solution to a microscopical study of the affected organ.

Under a microscope is placed a specimen of hepatised lung obtained from the body of a young and previously healthy adult. It is the so-called "red" hepatisation, the air-cells being filled with a meshwork of well-formed fibrin, which adheres with considerable tenacity to the alveolar walls. Scattered throughout this fibrin are variously sized epithelial elements, a few leucocytes and a fair proportion of red blood-cells. The alveolar walls themselves reveal but little alteration from the normal, and were attention directed to these alone it would probably be affirmed by most that they were in a state of health. A fibrinous network is further seen to exist in the lymphatics of the

adventitious structures of the organ, but beyond this there is little of note to be found. The next specimen reveals a very different state of matters. Herein the fibrinous network is still so far apparent, but it is no longer in contact with the alveolar wall. It appears to be disintegrating into a finely granular mass, which is separated frequently by a somewhat crescentic space from the wall. In this granular mass is a considerable sprinkling of fatty corpuscles with disintegrating nuclei, and somewhat similar though less degenerate corpuscles are likewise seen in fair numbers in the crescentic space. Closely inspecting the alveolar walls, it is found that they are lined with round and spindle-shaped bodies which are evidently the source of many of the corpuscles lying outside. Here, in fact, is seen the process of resolution in the hepatised lung. Very different, again, is the third specimen. It is a section of hepatised lung from an elderly and otherwise unhealthy man. The alveoli are densely packed with cells resembling leucocytes, amongst which not a vestige of fibrin is to be seen. In both lungs the hepatisation was everywhere uniformly thus. The walls of the air cells are, however, intact and their bloodvessels patent and containing blood. In this case also the alveolar walls are seen to be lined with round and spindle-like cells. Between these varieties many gradations are to be seen. Fibrin and corpuscles vary exceedingly. The earlier exudation may be chiefly fibrinous, and if resolution does not take place after the manner described the air cells will become crowded with cellular elements, replacing the fibrin. Sometimes, again, the corpuscles, shed early with the fibrin, are in considerable numbers, when they may exhibit the characters of true pus cells. Or it may be that the cellular element is the dominant one from the commencement, or even the sole element, forming the "yellow hepatisation" of Da Costa.

From the consideration of these phenomena I am led to recognise a typical resolving pneumonia, represented in the three stages of engorgement, hepatisation and resolution; and likewise a pneumonia whose leading feature is a corpuscular hepatisation terminating either in resolution or in destruction of the lung. In the first case we have resolution accomplished without the intervention of this corpuscular consolidation. The fibrinous exudation no doubt loses colour and becomes more cellular in the period of resolution, but this is distinct from corpuscular hepatisation. Hence the term "grey" hepatisation, though convenient, is otherwise objectionable and apt to mislead. The exudation in this speedily resolving pneumonia is identical with that obtained by Paget in the blisters of healthy individuals. On the other hand, in corpuscular hepatisation, the exudation resembles that obtained by the same illustrious observer in the blisters of cachectic persons and called by him "corpuscular lymph." The term "corpuscular" therefore seems to me to be the most authoritative definition for this form of consolidation. As to the light gained from a study of these exudations respecting the gravity of the disease, it may be said generally that when the disease proves fatal in the absence of corpuscular hepatisation we have to look to the severity of the constitutional symptoms, the blood poisoning, or the diminution of the breathing space in the lungs leading of course to failure of the circulation. When, however, the corpuscular lymph is abundant there is a local condition which in the absence of severe or sthenic symptoms is sufficient to cause a protracted resolution (and it is undoubted that this form of pneumonia may resolve) or else cause a destruction of the lung with its invariably fatal termination.

Regarding the derivation of the cellular elements found in the air cells in pneumonia, when these are abundant many of them have no doubt proceeded from the bloodvessels; but careful examination reveals—and this is particularly applicable to the stage of resolution—that a goodly proportion are derived from the epithelial elements lining the walls. Cornil and Ranvier, Rindfleisch, and others thus regarded pneumonia as terminating by a catarrhal pneumonia—a view which I cannot but regard as a travesty of inflammation. On the other hand, I believe that these corpuscles are merely the outcome of a superabundant growth of young epithelium, just as a similar overgrowth of new epithelium is formed on the surfaces of healing wounds.

Is this disease, then, to be regarded as a genuine inflammation? Inasmuch as no changes occur in the connective-tissue cells of the alveolar walls, the process can only be regarded as superficial, the local expression of a general disease. It is this absence of germination in the fixed tissue cells which is the sole anatomical distinction

<sup>1</sup> Substance of Remarks on Microscopical Preparations exhibited to the Pathological and Clinical Society of Glasgow, May 8th, 1892.

between acute pneumonia and acute broncho-pneumonia. I have elsewhere compared the pulmonary lesion of acute pneumonia to the joint lesion of acute rheumatism. As the former differs from broncho-pneumonia, so does the latter from acute synovitis. It is alleged—as for instance by Sturges and Coupland—that hepatisations of lung exist resembling that of acute pneumonia, which are in fact secondary to other diseases or own but a mechanical origin. But such cases are to be suspiciously regarded, and I am inclined to think that they are mostly genuine pneumonias, modified no doubt by the peculiar circumstances under which they occur.

Now as to the issues of this affection. Passing over destructive softening of the lung, abscess formation and gangrene, there remain two conditions which are no doubt rare and consequently ill-understood, but which are none the less highly important. One is somewhat vaguely termed “delayed resolution.” By this it is implied that dulness, riles and deficient breathing persist over a greater or less area of lung after the complete subsidence of all acute symptoms. This condition may be present for weeks or months and yet the lung may gradually “clear up” and become restored to health. This is an occurrence of considerable rarity, and, according to Wilks, in ninety-nine cases out of a hundred in which dulness persists after pneumonia it is due to pleurisy. In many cases there is no doubt empyema; but post-mortem, cases are likewise found showing persistent pulmonary consolidation, the air cells containing granular fibrin, mucous flakes and fatty cells, and the alveolar walls being lined with several rows of spindle cells. In such cases there is absence of interstitial changes, at least at first. If, however, complete recovery does not take place there remain two other possibilities. The hepatised area may break down into small abscesses and a form of phthisis is set up, or else the lesion contracts in area and cicatricial changes ensue, leading to a fibrous node, which becomes ultimately buried in emphysematous tissue.

The other issue of pneumonia to which I refer is in induration. Not, strictly speaking, in induration of the lung, but in induration of the pneumonic lung. The first step in this process is the germination (atypical to the disease) of the connective-tissue corpuscles of the alveolar walls. Next, the fibrinous exudation (never the corpuscular) becomes organised. To this form of induration I have applied the term “fibroid pneumonia,” for reasons which it is impossible here to discuss. Easily recognised at first, this remarkable transformation of the pneumonic products exhibits changes both of growth and of decay. To trace microscopically the evolution of fibroid pneumonia from its inception to its various terminations is a task of considerable difficulty. Outwardly indeed and to the naked eye this lung is sufficiently distinguished from Corrigan’s cirrhosis in its bulky character and the comparative absence of bronchiectasis. Further, it is found as an independent affection not consecutive to an acute pneumonia. But many cases of what is termed chronic pneumonia or interstitial pneumonia or Clark’s phthisis are in reality advanced cases of this fibroid pneumonia. No doubt this statement may be criticised and questioned, but it is none the less capable of proof, direct, continuous and complete.

Glasgow.

**LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY, LIMITED.**—A meeting of the members of the medical profession in Hampstead and the neighbourhood was held on June 25th at 127, Fellowes-road, South Hampstead, to establish a division of this Society for the north-western district of London. The Council of the Association had, under their articles, large powers, of which they only retained such as were absolutely necessary to secure the stability of the Society; all other powers were transferred to the Branch Councils, which were thoroughly representative of their respective districts.

**WEST RIDING MEDICAL CHARITABLE SOCIETY.**—The annual meeting of this Society was held at Wakefield on the 14th inst. After a lengthy conference of the officers, the chair was taken by Dr. Wright, president for the year. The report stated the Society to be in a prosperous condition, with about 450 members, whilst the invested capital amounted to upwards of £20,000. The claims of twenty-four applicants were investigated and awards were granted for the year amounting to £830. The Society was originated in 1829 in Wakefield.

## A Mirror

OF

## HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb. lib. iv. Prooemium.*

### MIDDLESEX HOSPITAL.

TWO SURGICAL CASES.

(Under the care of Mr. HULKE.)

**SURGEONS** are, it is believed, without exception agreed that lacerations of the urinary bladder, implicating those parts of the viscus where a complete rent of all its coats involves direct outflow of the urine into the peritoneal sac, should be immediately closed by suture. Here every hour’s delay adds to the already great danger of the injury, and were it possible to diagnose a *partial* laceration, implicating the mucosa and muscular walls, but leaving the peritoneum untorn, it is suggested that the safest course would be to treat this similarly, since with the infiltration and softening of the injured coats which will certainly ensue there must be a great risk of the peritoneal coat giving way, and thus of a *partial* becoming a *complete* laceration. Unfortunately such early precise recognition of the true nature of the injury as would warrant instant surgical interposition is not in every case possible. The initial shock is not always great and where present is not pathognomonic, and it may soon lessen. The presence of urine, as is well known, is not in all instances so poisonously irritating to the peritoneum as to immediately excite inflammation of the serous membrane. Doubtless much depends on the quality of the urine. The analogy of cellular urinary extravasation proves this; thus a familiar instance is the rapid sequence of gangrene of the perineal tissues and scrotum upon the extravasation into them of urine contaminated with inflammatory substances and with products of decomposition, such as is not uncommon where the urethra gives way behind a stricture in concurrence with a chronic cystitis, whereas extravasation of normal urine—particularly the limpid urine of young persons—such as occurs with fractures of pelvis, occasions swelling, which for some time may differ but slightly from that of a simple œdema. Of course, if on introducing a catheter no, or very little, urine is found in the bladder, whereas on gently pushing the instrument a little further in a larger quantity escapes, this affords a strong presumption of a complete laceration; and this presumption becomes a certainty if on depressing the handle the vesical end of the catheter mounts and projects the abdominal wall over the pubis. These signs are, however, not in every case patent and obviously recognisable, even where a rent is complete. That this is a fair statement of the difficulties surrounding the diagnosis is illustrated by the following case. Here the bloody tinge of the urine raised a strong presumption of injury of the bladder, but the quantity of urine that the bladder apparently held seemed to contraindicate a complete rent; the early subsidence of the symptoms of great shock and the retardation of symptoms of peritonitis conspired to mislead and so led to the postponement of laparotomy, which, had the true nature of the accident been immediately perceived, would have been undertaken with a reasonable prospect of the patient’s recovery.

**CASE 1.** *Extensive laceration of the urinary bladder; laparotomy and suture of rent; death from peritonitis.*—C. E—, aged thirty-three, in the evening of Jan. 14th, 1892, in rough horse-play with others with whom he had been drinking, was butted sharply in the abdomen. He at once felt great pain and he was shortly after this brought to the hospital at 9 P.M. He had, he said, passed urine two hours previously. On reception into Founder ward the house surgeon noticed that he had an anxious expression, coldness of surface, a small, weak, slow pulse. He complained of severe pain in the lower part of the abdomen and of an urgent desire to micturate. The front of the abdomen was everywhere resonant. A catheter was passed without difficulty and some urine (roughly judged by the ward sister to be six to eight ounces), very slightly tinged with blood, was drawn

off. On withdrawing the catheter a small blood-clot was noticed entangled in its eye. At six o'clock on the following morning, there being again an urgent wish to micturate, the house surgeon again used the catheter and drew off nearly as much urine as on the preceding evening; it was still slightly blood-tinged. At 10 A.M. the pulse was 126 and the temperature 99.7°. At the midday visit, when he was first seen by Mr. Hulke, the symptoms of great shock had passed off. He complained of some pain over the pubes, where there was found a central dullness suggestive of a full bladder. With a catheter twenty-two ounces of urine, very slightly blood-tinged, were drawn off, after which the dull area was found resonant. When in the bladder the catheter was gently used as a sound for the detection of a rent in the viscus, and with a negative result. The accumulation of so large a quantity of urine apparently in the bladder seemed incompatible with the supposition of a complete rent involving its peritoneal coat and allowing the efflux of urine from the cavity of the bladder into the peritoneal sac; and to justify the diagnosis made by the admitting officer and house surgeon of shock from severe blow on the abdomen, with perhaps bruising and possibly partial laceration of the bladder or a slight laceration of that part of it uncovered by peritoneum, a close watch was kept for any sign of extravasation into the pelvic cellular tissue. In the early evening increased pain in the abdomen and some tenderness and vomiting supervened. This was attributed to the super-vention of peritonitis. Small doses of morphia were given hypodermically and at 12 midnight leeches were put on. This was followed by ease and apparent improvement; he took and retained liquid nourishment.

16th.—10.30 A.M.: Temperature 100°; easier. In the evening vomiting returned, and he had more pain in the abdomen, which had become distended; urine drawn off is turbid and offensive; cystitis was present.

17th.—Vomiting; much abdominal pain and great distension. An exploratory laparotomy, which had been considered and previously thought unwarranted, was decided on. The abdomen was opened—after passing the catheter and withdrawing three ounces of offensive bloody urine—by an incision three inches long, just above the pubis and afterwards extended nearly to the umbilicus. A large extravasation of blood in the sub-peritoneal cellular tissue was found behind the rectus muscle. On dividing the peritoneum several ounces of grumous bloody fluid escaped. At first only coils of highly congested small intestine, coated and agglutinated by recent exudation, were apparent, but on displacing these gently upwards much highly offensive puriform fluid welled up from the situation of the urinary bladder, and when this had been sponged out a rent, nearly sagittal in direction, about two inches and a half long in the posterior wall of the bladder, was brought into view. Its edges were swollen, soft and stained with infiltrated blood. The rent was closed with a double row of closely placed sutures, the deeper series including all the tissues down to the mucosa and the superficial series, the peritoneum with perhaps a thin plane of muscular tissue. The bladder was then injected with a watery solution of boric acid and proved watertight. The peritoneum was flushed out and cleaned. The abdominal wound was sutured in the usual manner and the bladder was kept drained by a full-sized soft red-rubber catheter. For two hours after the patient was put back in bed vomiting ceased, but it soon returned. The peritonitis ran a rapidly fatal course and death occurred next morning (the 18th) at 6 o'clock. At the necropsy the sutured rent in the bladder was found still watertight, no leakage occurring under considerable pressure. The pathological appearances observed were those of an intense, widely diffused peritonitis, which had evidently its focus in the vesical injury.

CASE 2. *Immense dermoid cyst deeply seated in thigh; extirpation; recovery.*—Very many, perhaps the majority, of dermoid cysts other than those occurring in relation with the ovaries and their annexes are met with in situations suggesting genetic relation with embryonic clefts, using this latter term in a very wide sense; but this explanation is not universally applicable, and the present is an instance of such exception, which, on account of its singularity, seems to deserve publication. A tall, stout, rather muscular brunette, aged forty-seven years, was admitted into Bird ward on Jan. 15th last, having an immense swelling in the inner part of the right thigh. It extended from the groin to one hand-breadth from the knee, and it had a transverse girth equal to if not greater than that of the thigh itself. Near its lower end the overlying skin in a circular area of several

inches was red, and the subcutaneous tissues corresponding to this were matted and œdematous. In the middle of this red œdematous area was a small ulcerated spot from which oozed a turbid, milky, inodorous fluid. Except within this area where the wave was damped by the overlying œdema, this great swelling everywhere distinctly fluctuated. By its great bulk and position the tumour embarrassed the patient much in walking, giving her a very awkward gait, in spite of which inconvenience she had continued to work until the skin inflamed and broke, which finally obliged her to seek advice. When lying on her back, as in bed, with her lower limbs extended, the inner part of the tumour covered her vulva and rested on the inner side and the front of the left thigh. It was observed that during active contraction of the adductor longus muscle the tumour became firmer, evidencing its compression by this muscle, and it was further noticed that the limb having been passively abducted, in which attitude the tumour rested flaccidly on the mattress, contraction of the adductor magnus caused the tumour to rise up off the bed and made it tense. At the upper and inner part of the tumour the adductor gracilis was traceable on to its surface; whilst lower down the front and inner part of the tumour was obliquely crossed by the sartorius. The fingertips could be pressed down between the upper border of the tumour and the brim of the pelvis, so making it evident that the tumour did not extend under Poupart's ligament. The patient's account of the tumour was remarkable. It had existed from her childhood. In her eleventh year, the swelling being then as large as a small orange and at the "top of her thigh," her mother sought medical advice for it, and being told that any operation for its removal would be dangerous and could not be undertaken without risk to the child's life, she later exacted from her a promise that she would never permit any operation to be performed upon her. The patient had therefore uncomplainingly borne with the increasing inconvenience until at last her condition became unendurable.

Fluctuation was so apparent that of the cystic nature of the tumour there could not be any doubt; and the nearly equal distinctness of the percussion wave through the great swelling in every direction established its unilocular character. The character of the fluid oozing from the little opening described showed that sebaceous material was one of the contents of the cyst. The differential diagnosis was thus narrowed to the discrimination between a sebaceous retention-cyst, or wen, and a dermoid. But wens can only arise where sebaceous glands are present; they are therefore superficially seated in intimate relation with the integument; but this huge cyst was plainly seated under the deep fascia, amongst the muscles, and this circumstance favoured the supposition of its being a dermoid. Its locality, the thigh, though unusual for a dermoid, could not be taken to exclude this kind, since, although, as already mentioned in numerous instances, dermoids show a distinct preference for the sites of embryonic clefts, into which it is conceivable that epiblastic tissues may become fixed and later give rise to cysts, yet other instances of dermoids have been met with where such mode of origin is less obvious—e.g., dermoids in the brain—and yet others have been recorded where such an origin seems quite excluded—e.g., dermoids in solid abdominal organs as in the liver. That this cyst had a pelvic origin was very improbable, seeing that its upper border did not transgress the line of Poupart's ligament; but a pelvic communication through the obturator opening could not be absolutely excluded and the possible existence of such was hinted by the ascertained relations of the cyst to the adductor muscles. However, upon a consideration of all the circumstances, an extension of the cyst from the pelvis through the obturator foramen into the thigh appeared so extremely improbable that it was not deemed necessary to settle this by a vaginal examination, the patient being an unmarried person.

The practicability of a complete extirpation appeared highly probable, and since it offered the only prospect of relief, it was advised and was accepted by the patient. It was done on Jan. 17th, the removal of the cyst being effected through a long incision from the groin to the lower end of the tumour. The operation was a rather long one, owing to the close adhesion of the cyst wall to surrounding parts, and particularly along its outer side, where its close relations to the large vessels necessitated cautious dissection. At its uppermost limit, where the cyst had a leathery thickness and toughness and which was presumably its oldest part, it was intimately attached to the periosteum of the front of the os pubis,

just under the attachment to this of the adductor longus; and here, springing from the inner surface of the cyst, were two little tufts of black hair. Hæmorrhage having been arrested—a rather large number of arteries required tying—the wound was flushed with hot water and then with mercuric chloride, and its edges brought together with aseptic silk sutures. Three drainage-tubes were inserted. An attempt was made to keep the superficial and deep parts of the wound in contact by aseptic cushions and bandaging, and the whole limb was fixed by the aid of a long outside thigh-splint.

In spite of much care to secure and maintain an aseptic condition suppuration ensued at the end of a week. This seemed, probably rightly, attributable to much derangement of the dressings through the patient's great restlessness during the first days after the operation. The integumental incision closed in the greatest part of its extent immediately, but troublesome sinuses persisted during several weeks. On April 28th the patient was sent to the seaside, whence she returned on May 12th looking remarkably well. She then walked "with perfect comfort" and she said that her right leg was nearly as strong and able as her left. She has since resumed her occupation, cicatrization of the entire wound has long been complete and she says she has better health than she had enjoyed for years previously.

## Medical Societies.

### OBSTETRICAL SOCIETY OF LONDON.

#### *On Menstruation in Cases of Backward Displacement of the Uterus.*

A MEETING was held on July 6th, Dr. J. Watt Black President, in the chair.

Dr. HERMAN read a paper on Menstruation in Cases of Backward Displacement of the Uterus. The paper was based upon an analysis of 388 cases of retroversion and retroflexion of the uterus. In about 60 per cent. of the entire number there was no alteration in the quantity of the menstrual flow. In some 20 per cent. there was amenorrhœa, but in every instance of amenorrhœa it was accounted for by causes irrespective of the displacement. In about 50 per cent. of those in whom the menstrual function was not in abeyance there was no alteration in the quantity. In nearly 40 per cent. hæmorrhage was increased. In patients of the same class as those in whom retroversion and retroflexion commonly occur, but whose uteri are normal as to position, the frequency of incidence of causes of hæmorrhage other than gross organic disease and pregnancy is probably about 30 per cent. The proportion of women with backward displacements who suffered from hæmorrhage was thus larger by about 10 per cent. than the proportion of women whose uteri are normal in position. It was therefore reasonable to believe that in this small proportion of cases the hæmorrhage was due to the displacement. Among women with backward displacement of the uterus in whom the menstrual function was not in abeyance pain at the period was absent in only about 20 per cent. Menstrual pain was commoner in those women who had backward displacement of the uterus than in those who had not; and also in those who had increased hæmorrhage.—Dr. HAYES thought the value of the paper impaired by the fact that the amount of hæmorrhage in the cases was not specified. Hæmorrhage varied so much even in healthy women under trifling distractions that comparisons were difficult and misleading. Again, in backward displacements the ovaries were often prolapsed, giving rise to troublesome bleeding; in the paper no mention was made of the position of the ovaries. Respecting the dysmenorrhœa, he would have liked some specification of the amount of pain in the individual cases.—Dr. RUMFORD asked how many of the 40 per cent. of the women with increased menstrual flow were multiparæ and what was the average number of children per woman. He thought subinvolution, as well as retroflexion, might account for the menorrhagia.—Dr. HEYWOOD SMITH asked if any observations had been made among so large a number of recorded cases as to the number of cases of retroflexion of the gravid uterus.—Dr. ADDINSELL made some remarks.—Dr. HERMAN, in reply, said that no doubt in many of his cases subinvolution existed; this was also present among the cases with which he had compared those of

displacement. He did not think subinvolution was especially common in multiparæ. Prolapse of ovary was present in many of his cases, but he did not know the exact number. He had often observed pregnancy occur in backward displacement, though he could not, without reference to his case-books, say how often. In a paper read in December, 1891, he had discussed this point. He found the sound generally caused pain in patients of all classes when it passed the internal os, but he had not perceived anything to make him think there was stricture at the internal os.

Mr. MEREDITH contributed notes on Two Cases of Double Ovariectomy during Pregnancy. In the first case, a primipara, two papillomatous cysts were removed at the third month of pregnancy. Extensive adhesions necessitated the use of a drainage-tube for thirty-six hours, yet the patient convalesced uninterruptedly well, and was delivered at full term of a well-developed boy. In the second case, a multipara, aged thirty-one, the left ovary was a multilocular cystoma with a recently twisted pedicle; the right ovary was a dermoid cyst. No drainage-tube was used. The patient recovered perfectly and was safely delivered at term of a daughter. In both cases delivery was followed by normal contraction of the uterus and by perfect involution subsequently. Only four cases of double ovariectomy during pregnancy had been previously recorded. All the mothers recovered, but in only two was a living child born, one prematurely at the eighth month and the other at full term.—Mr. DORAN said it was right to remove an ovarian cyst during pregnancy, and if on removing one ovary the other was found cystic it also ought to be removed; indeed, its removal hardly increased the chances of abortion, and if left behind after irritation by handling, it might set up uterine contractions. The Fallopian tube in these cases was specially sensitive. The evidence that ovulation continued when both ovaries were in an advanced stage of cystic disease implied that when thus diseased they influenced the uterus prejudicially, hence their thorough removal in cases of pregnancy was highly desirable.—Dr. LEWERS was much interested in the first case, where a drainage-tube had been used and where there were papillary growths on the outer aspect of the cysts without infection of the peritoneum. He thought it would be difficult to use a drainage-tube when pregnancy had advanced, as Douglas's pouch was then practically obliterated by the gravid uterus. He had had a case of double ovariectomy recently where there were numerous papillary growths from the outer aspect of the cysts without any infection of the peritoneum, and not due to the intra-cystic growth bursting through the cyst wall. Probably the papillary growths had existed a considerable time, as three years before he operated the patient had been advised elsewhere against operation on the supposition that she had pelvic cancer.—After some remarks by Mr. BLAND SUTTON and Dr. HEYWOOD SMITH, Mr. MEREDITH briefly replied and the meeting closed.

The following specimens were shown:—

- Dr. LEWERS: (a) Primary Carcinoma of Uterine Body; (b) Microscopic Sections of same.
- Dr. DES VŒUX: Hæmorrhagic Ovaries.
- Mr. BLAND SUTTON: (a) Decidual Cast from Case of Ectopic Gestation; (b) Papillomatous Ovary.
- Dr. CULLINGWORTH: Two Cases of Pyo-salpinx.
- Dr. W. DUNCAN: Knitting-needle removed from Pregnant Uterus by Abdominal Section.

### OPHTHALMOLOGICAL SOCIETY.

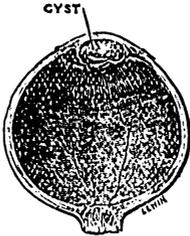

*Implantation Cyst of the Iris after Cataract Extraction.—Acidental Vaccinia of the Eyelids.—Symmetrical Dacryoadenitis.*

An ordinary meeting of this Society was held on July 8th, the President, Mr. Henry Power, F.R.C.S., in the chair.

Mr. RICHARDSON CROSS and Mr. TREACHER COLLINS contributed a paper on two cases of Implantation Cyst of the Iris after Cataract Extraction. The first was that of a woman aged sixty-four, who had had an uncomplicated extraction of cataract with iridectomy performed on her left eye, and subsequently obtained vision which enabled her to see to read and sew. Seven months after the operation an attack of acute glaucoma came on and the sight rapidly failed. The eye was excised a year later. The pathological examination of the eyeball showed that there was a large cyst in the

anterior chamber lined throughout by laminated epithelium. It was bounded in front by the posterior surface of the cornea, below by the anterior surface of the iris, which curved round it, and behind partly by the lens capsule and partly by the hyaloid of the vitreous. The iris, where it ceased to be in contact with the cyst, was in apposition with the cornea.

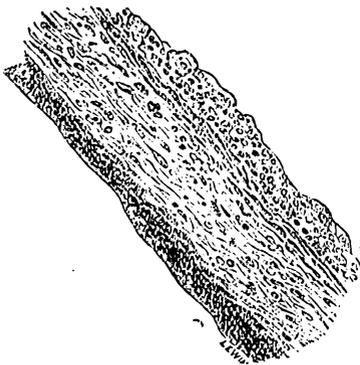

FIG. 1.

Lateral half of the eye of Case 1, showing the position of the cyst.

The angle of the anterior chamber was closed in its entire circumference, a portion of the root of the iris having been left above in the situation of the coloboma. The optic disc was cupped. The second case was that of a man aged forty-one, who had a cataract extracted from his left eye with iridectomy. At the conclusion of the operation the anterior chamber was washed out with a solution of the biniodide of mercury of the strength of 1 in 25,000. Striated keratitis came on subsequently and persisted. Seven months later a thick opaque membrane filling the coloboma was needled; after this the eye continued painful and bloodshot, the cornea became more hazy, and new bloodvessels developed in it. The eyeball was ultimately excised two years after the extraction. At the pathological examination a cyst was found in the anterior chamber lined by laminated epithelium closely resembling that on the surface of the cornea, the most flattened cells being towards the interior of the cyst. In shape it was somewhat triangular, one side being in contact with

FIG 2

Laminated epithelium lining the cyst, on the anterior surface of the iris.

the cornea, another with the iris and a third with the lens, capsule and vitreous. For the determination of the mode of formation of these cysts the authors considered that it was necessary to ascertain the origin of the laminated epithelium found lining them. Two possible sources suggested themselves:—(1) That it was derived from proliferation of the endothelium lining, Descemet's membrane and the anterior surface of the iris; (2) that some of the surface epithelium was carried in at the time of the operation and had subsequently proliferated. The latter view seemed the more probable because the epithelium was found on the surface of the lens capsule and the hyaloid of the vitreous, and was not confined to the iris and Descemet's membrane, and because epithelial-lined cysts had been produced experimentally in rabbits' eyes by such implantations of surface epithelium. The first case was of additional interest from the fact that the eye became glaucomatous. The cyst, which filled the whole of the coloboma, must have prevented fluids passing through it into the anterior chamber. Consequently the iris became pressed forwards into contact with the cornea and folded round the cyst, very much as it is round a lens when

dislocated into the anterior chamber and blocking the pupil. In this way the whole of the filtration area of the cornea became closed by the periphery of the iris and the exit of intra-ocular fluids arrested. The paper was illustrated by lantern slides.—The PRESIDENT thought it remarkable that cysts from implantation of surface epithelium were not more common after extraction of cataract.—Mr. HULKE said that cysts in relation with the iris were usually the consequence of injury, but that the evidence in the cases brought forward showed satisfactorily that these resulted from operation.

Mr. TATHAM THOMPSON reported a case of Accidental Vaccinia of the Eyelids, occurring in a man aged thirty-eight. The lids were œdematous and painful and at the outer canthus the edges of both lids were involved in a purulent ulcer with indurated margins. There was great tenderness of the parts and painful enlargement of the glands at the angle of the jaw and down the sterno-mastoid. The man's child had been vaccinated a short time previously and his wife had been accidentally inoculated therefrom. The man had suffered from slight marginal blepharitis, with excoriation at the outer canthus, and the inoculation had probably occurred at that point.

Mr. SIMON SNELL communicated a paper on a case of Symmetrical Dacryo-adenitis. The patient was a married woman aged thirty-six, who came under observation on March 22nd. Ten weeks previously the right eye became inflamed; this was soon followed by a swelling beneath the upper lid, which gradually increased and was accompanied by pain. A similar condition on the left side had begun a week before she came to the hospital. Both lacrymal glands were enlarged, hard and tender to the touch, the right being much more affected than the left. The history threw no light upon the cause of the disease. In spite of the absence of evidence of syphilis, iodide of potassium was given (five grains) three times a day and was rapidly followed by subsidence of the swelling and other signs. During the time the lacrymal glands were decidedly enlarged there was an almost complete absence of tears on the right side and a noticeable diminution in their secretion on the left side.

The following cases and card specimens were shown:—  
Mr. STEPHENSON: A Movable Stencil Plate for Accurate Delineation of the Meridian of the Retina.

Mr. LINDSAY JOHNSON: A Modification of Priestley Smith's Perimeter.

Mr. JULER: Fundus Changes (after Influenza) resembling Albuminuric Retinitis.

Mr. SHEPHERD: A Cutting Strabismus Hook.

Mr. TATHAM THOMPSON: (1) Episcleral Gumma; (2) Rupture of Choroid and Retina in the Region of the Macula; (3) Rodent Ulcer of Face; (4) Recurrent Sarcoma of Orbit.

Mr. BRAILEY: Transplantation of Flap of Skin from the Arm for Ectropion.

Dr. WOOD: Partial Detachment of Retina, with Unusual Dilatation of Vessels.

The annual general meeting was held at 9.30, and the following list of officers elected for the ensuing year:—  
President: Mr. Henry Power. Vice-Presidents: Dr. James Bankart, Exeter; Dr. John Hughlings Jackson; Mr. George Lawson; Dr. William M. Ord; Dr. D. C. Lloyd Owen, Birmingham; Mr. Simeon Snell, Sheffield; and Mr. John Tweedy. Treasurer: Mr. George Cowell. Secretaries: Dr. Charles E. Beevor and Mr. Gustavus Hartridge. Librarian: Mr. W. Adams Frost. Other Members of the Council: Dr. James Anderson; Mr. F. Richardson Cross, Bristol; Dr. James McKenzie Davidson, Aberdeen; Mr. Robert W. Doyne, Oxford; Mr. Henry Eales, Birmingham; Mr. J. R. Lunn; Dr. J. A. Ormerod; Mr. Herbert W. Page; Mr. D. D. Redmond, Dublin; Dr. W. C. Rockliffe, Hull; Dr. G. H. Savage; and Dr. A. Quarry Silcock.

ASSOCIATION FOR THE ORAL INSTRUCTION OF THE DEAF AND DUMB.—The annual meeting of this Association was held on the 13th inst. The report stated that thirty-four boys and fifteen girls had attended the courses of lectures during the past year, which were given under the German oral system. The committee regretted that they had not been able to supply as many teachers as were wanted, particularly for private tuition, and expressed a hope that the Training College would receive more pupils. The cash statement showed a slight deficiency, and as the Association is dependent on subscriptions, an earnest appeal was made for additional funds.

## Reviews and Notices of Books.

*A Handbook of Hygiene and Sanitary Science.* By GEORGE WILSON, M.A., M.D., F.R.S. Edin., D.P.H. Camb., Fellow of the Chemical Society, &c. Seventh Edition. London: J. & A. Churchill. 1892.

THE merits of a book which has run through several editions must by this time have been so well recognised as to need no lengthy notice in our columns. And yet the simple fact that a book has reached the seventh edition arrests attention and supplies its own comment. If it had not filled a void and furnished much valuable and useful information it is clear that it could not have attained the popularity which "Wilson's Handbook of Hygiene" has secured.

The present edition has been enlarged to the extent of more than 200 pages, and contains a number of new woodcuts illustrative of those parts of it which deal with ventilation, sanitary fittings and drainage, house building, isolation hospitals, and parasitic diseases. It seems to have been carefully revised and brought up to date, many of the chapters having been wholly or in great part rewritten, whilst two new chapters on climate and meteorology and disposal of the dead have been added. When a man has to select a cheese he can judge of its quality by a sample from its interior and happily does not require to eat the whole to form a correct judgment. We have gone further than one sample, however, for we have taken a good many pages as samples and compared some sections of this seventh edition with those of an earlier edition of the same work. The chapters on Food, Removal of Sewage and House Refuse, Sewage Disposal, Communicable Disease with its summary of the most recent advances in bacteriological research, and that on Disinfection and Disease Prevention, are honestly and well done. The chapter on Vital Statistics is a difficult one to arrange properly and lucidly, so as to explain methods and guard against the various pitfalls in the path of the enthusiastic but unwary novice in statistical science. *In passant* we may say that we do not see any allusion, beyond the brief remark at page 246, to the contamination of water with zinc which has been referred to by some chemists and authors. A great deal of labour and care must have been expended on the composition and compilation of this handbook. The subject of Sanitary Science is a big and growing one, and the additions to our sanitary legislation of late years have enlarged the sphere of functions, increased the responsibility, and multiplied the duties, of all concerned with public health. Medical officials, candidates for public health diplomas, local surveyors and sanitary inspectors generally will find a great quantity of information in this volume which it concerns them to know. We can honestly speak of it in terms of high commendation.

*The Essentials of Histology.* By E. A. SCHÄFER, F.R.S., Jodrell Professor of Physiology in University College, London. London: Longman, Green and Co. 1892.

A THIRD EDITION of this well-known work needs but little recommendation. The object of the book is to supply the student with directions for the microscopical examination of the tissues. A proper knowledge of histology can only be obtained by a practical study of each individual organ. It is not sufficient that the student should be provided with a series of prepared specimens and be told to "read them up" from a book; he should obtain the organs and prepare the sections for himself, and in so doing he will secure a far better and more lasting idea of the structure of the tissues than by any other means. This book is divided into forty-five lessons, each of which would occupy a class from

one to three hours. The methods may be thoroughly trusted, as only those "are recommended upon which experience has proved that full dependence can be placed." Needless to say that with such an author as Professor Schäfer the work is complete in every detail.

Each "lesson" commences with practical directions as to how to secure and prepare the specimens or sections and then full descriptions are given as to what should be observed. The illustrations are numerous and excellent and greatly add to the value of the book. One of the greatest difficulties experienced by students is to understand the structure of the nervous system. It is necessarily by no means easy to demonstrate clearly the course of the numerous fibres and the arrangements of the cells and ganglia, but by the aid of diagrams and drawings the author has succeeded in laying before the reader by far the most succinct and satisfactory description which we have ever seen. Take, for example, the structure of the cerebrum. Six sections taken from various parts of the hemisphere, and admirably reproduced, give as good an idea as possible of the arrangement of the various layers, whilst the full descriptions which accompany them will teach the student in a comparatively short time all that he need know on this complex subject. By the previous editions the success of the book has been ensured, and we can only pronounce the present edition a great improvement on the two which have gone before, excellent though they were. We cordially recommend the work to all students.

*Transactions of the Seventh International Congress of Hygiene and Demography.* Vol. XI.: Indian Hygiene and Demography. Edited by C. E. SHELLEY, M.A., M.D., assisted by the Hon. Secretary of the Indian Committee. London: Eyre and Spottiswoode. 1892.

THE labour of producing the voluminous transactions of the great Congress which was held in London last year is steadily progressing, and certainly few volumes can be more important than the one before us. The book opens with a lengthy, valuable and elaborate paper by Sir William Moore, K.C.I.E., on Sanitary Progress in India, in which facts collected from a great variety of sources are brought together, while the results of sanitation are shown by many statistical tables. This paper makes it very clear that sanitation in a tropical country has its special difficulties and that methods which work well enough here may fail in India. This paper, as well as those by Surgeon-Major Hendley, C.I.E., on Sanitation in Rajputana, by Surgeon-Major Kirtikar on the Sanitary Wants of the Bombay Presidency, by Assistant Surgeon Ramji Ghole on the Hygienic and Demographic Condition of India, by Mr. Dhurandhar on the Sanitary Condition of Towns and Villages, and by Mr. Lionel Ashburner on Legislative Action as applied to Village Sanitation, make it plain that hygiene in India, to be successful, must begin in the homes of the people and that the apathy, ignorance and superstition of the people constitute a dead weight with which it is an almost hopeless task to attempt to deal. The papers by the native gentlemen who made communications to the Congress will be read with special interest, combining as they do an accurate knowledge of the natives and their wants with a knowledge of medicine and sanitation, for the most part acquired in Europe or at the hands of European teachers. Mr. Bypamjee's paper on Bhavnagar, Dr. Fernando's paper on Ceylon, Mr. Chotalali's paper on the City of Ahmedabad, Mr. Ollivant's paper on Bombay, and Major Temple's paper on the City of Rangoon all serve to bring prominently before the mind's eye the actual state of sanitation in our great Indian dependency and the possibilities of effecting improvements in the future.

Certain other papers which were read in other sections of the Congress have been added to this volume and are here printed in duplicate, because it was felt that the whole of the

Indian papers should be included in one volume in order to render the book as useful as possible to those who are interested in Indian sanitation. These supplementary papers include the Prevention of Fever, by Sir W. Moore; Sanitation in India, by Mr. Baldwin Latham; the Water-supply of India, by Surgeon-Major Pringle; Enteric Fever in India, by Professor Notter; Hygiene for the Zenanas, by Surgeon-General Francis; and two papers on Factory Legislation, by Mr. Holt Hallett and Dr. Bahadurji. In conclusion, as this is a matter which affects the public at large, we may state that this volume may be had separately for 2s. 6d., and we earnestly hope that it will be widely read.

*The Science and Art of Midwifery.* By WILLIAM THOMPSON LUSK, A.M., M.D. Fourth Edition. London: H. K. Lewis. 1892.

DR. LUSK'S excellent treatise has in former editions proved to be to both students and practitioners a safe guide to the practice of midwifery. This new edition, which in many parts has been entirely rewritten, embodies all the most important advances in obstetric science which have been made since the appearance of the previous issue in 1885. Many modifications have taken place during these years in the theory and practice of this science consequent upon more careful investigations by several observers in anatomy and pathology. Most of these results are set forth by Dr. Lusk with due discrimination. The modern development of aseptic surgery is manifest in the treatment of many of the complications of the puerperal state. The book contains two very instructive chapters dealing with the latest phases of questions relating to the febrile conditions which occur during the puerperium, and full justice is done in the work to the bacteriologists whose researches have given us the true explanation of these much-dreaded complications.

*Notes on Dental Practice.* By HENRY G. QUINBY, L.D.S.I. London: J. & A. Churchill. 1892.

A SECOND EDITION of Mr. Quinby's *Notes on Dental Practice* is a welcome addition to dental literature. It comprises the teaching of a conscientious worker of long experience, and will well repay perusal by the student or practitioner. Perhaps the most valuable portion of the book is that relating to the treatment of the temporary teeth, which are too commonly regarded by parents as of little importance, whereas their welfare has a profound influence upon their successors. When the first teeth are decayed the first step is to gain the confidence of the little patient by gentleness and kindness and to correct the preconceived idea of dread of a visit to the dentist. Fillings should be of a simple character, of which guttapercha, all things considered, is the best. Gold stoppings in such cases are not only unnecessary but absurd. Extraction is rarely necessary as a mere means of relief of pain, and should only on exceptional occasions be resorted to; for premature removal often results in a contraction of the alveolus, which impedes the eruption of the permanent tooth, and, further, if performed early, the developing tooth may from the force used be wrenched out of its normal position. When second dentition is in progress it is invariably bad practice, although too common, to remove two temporary teeth to make room for a permanent one. In the chapter devoted to the subject of extraction as a means of preventing decay the author makes the pertinent remark that in deciding upon this procedure the history of other members of the same family should always be taken into consideration. In the treatment of irregularities many practical points are brought forward, and the importance of securing the active coöperation of the parents is impressed upon the reader. When dealing with the subject of the treatment of adult teeth Mr. Quinby's remark is surely not to be taken seriously when

he says of the rubber dam and the saliva ejector that their chief use is "for the convenience of the dentist, because it enables him to leave his patient, without danger to his work, and go to his lunch or see another case for a moment," but rather as a protest against the abuse of these adjuncts—valuable alike from the operator's and the patient's point of view to the dental armamentarium. The book closes with a chapter on anæsthetics for dental purposes written by Dr. Briggs.

## Analytical Records.

NATRIUM SALICYLICUM PURISS. PULV. AND ACIDUM SALICYLICUM PURISS. PULV. (DR. HEINRICH BYK, BERLIN).  
(R. W. GREFF & Co., 20, MINCING-LANE.)

IN consequence of the disturbances of a more or less severe, and in some instances grave, nature which have followed on the employment of salicylic acid synthetically prepared from phenol, several chemists have been induced to investigate the subject, with a view of discovering in what respects the artificial acid differs chemically from that obtained from oil of winter green, or from that interesting body, salicin. Eventually the difference was found to be due chiefly to the presence in the artificial acid of creasotic acid, which results from the use of impure phenol and also of para-hydroxybenzoic acid and hydroxyisonaphthalic acid in its manufacture. The presence of the two latter substances is referable either to the use of caustic soda containing potash or to undue raising or lowering of the temperature during manufacture. Professor Charteris, in a series of comparative experiments on rabbits, showed that natural salicylic acid in 10-grain doses and the sodium salt in 32-grain doses had no deleterious effects on rabbits weighing 2½ lb. Artificial salicylic acid, on the other hand, in 10-grain doses and the sodium salt prepared from the artificial acid in 18-grain doses caused the death of rabbits of the same weight. In fact the very best specimens of the artificial acid sold as chemically pure proved fatal to two rabbits, while in others it caused marked prostration and paralysis. With less pure specimens fatal results followed. It is satisfactory therefore to learn that a simple process has since been adopted by which these powerfully toxic impurities may be carefully removed and a perfectly pure acid obtained. The process consists merely in treating a hot aqueous solution of the artificial acid with chalk till it becomes neutral. The liquid is allowed to cool, when the sparingly soluble calcium salicylate separates out in hard glistening crystals, while the impurities remain in solution. The calcium salt so obtained is recrystallised, more than once if necessary, from hot water and then decomposed with hydrochloric acid. The salicylic acid thus set free is washed with cold water and finally crystallised with pure spirit. So prepared the acid occurs in large, well-formed, prismatic crystals, which are exactly similar in appearance to the crystals of the natural acid; and the melting point, solubility and other properties of the two substances are identical. Moreover, physiological experiments with this purified acid showed that even with larger doses there was no paralysis or depression when it was administered to rabbits. We are not aware whether the acid above or the sodium salt was prepared in this way, but according to the chemical and physical tests we applied it is analogous in all respects to the natural product. The melting point was exactly 156° C., the crystals were well formed, and no carbolic acid could be detected. It crystallised satisfactorily also from spirit, while it gave an exact equivalent when titrated with standard alkali. Both preparations are evidently of great purity and may accordingly be used with confidence for medicinal purposes.

**SYRUP CHLORIDE OF IRON (WELD'S).**

(PARKE, DAVIS, AND CO., 43 &amp; 44, HOLBORN-VIADUCT.)

Each tablespoonful of this preparation is said to be equivalent to twenty drops of the official tinctura ferri perchloridi and our analysis practically confirms this statement. It is acid to test paper, gives a blue precipitate with prussiate of potash, increased on the addition of hydrochloric acid; no colouration with sulphocyanide of potassium until similarly treated, and no precipitate with ammonium hydrate. Alkaline copper solution is rapidly reduced. These results contribute to show that the preparation consists of a carefully made combination of syrup with perchloride of iron. Although it is characterised by a sweet and inky taste, it has not that marked action on the teeth which forms a drawback to the general administration of ordinary compounds of iron. In short, it would seem to possess all the advantages of an efficient iron salt.

**INVALID NOURISHING STOUT.**

(J. T. USHER, HORFIELD-ROAD BREWERY, BRISTOL.)

Malt liquors when honestly prepared are not only a wholesome form of tonic and stimulating beverage, but possessing in addition distinct nutritious qualities, are often of value to invalids. When taken habitually beer tends, it is well known, to induce a state of fulness and plethora of the system and a disposition in some people to accumulate fat. The nutritive matter of beer occurs chiefly in the form of soluble carbohydrates (dextrin, malt sugar) and also of albuminates in small quantity, while salts of potassium, and especially phosphate, are a normal and abundant constituent of the ash of malt. The digestive action of beer is referable, more perhaps than anything else, to the free carbonic acid contained in it, as the activity of the diastase of the malt is destroyed in the boiling of the wort. Bottled beer, therefore, is more freely to be recommended for dietetic purposes. According to our examination the sample of stout prepared by the above firm is well brewed, ripe and of mellow full taste. Analysis showed a normal proportion of nutritious extractives with a corresponding amount of mineral matter, essentially potassium phosphate, while alcohol was present to a suitable extent. The figures actually gained were as follows:—Absolute alcohol 5.65 per cent. by weight, 7.00 per cent. by volume; extract 6.72 per cent.; mineral matter 0.52 per cent. The product compares favourably, therefore, with other brands.

**NOTESCO LIQUEUR.**

(NOTESCO Co., 380, OXFORD-STREET, W.)

The claims made in respect of this preparation are many, but our examination does not enable us to confirm the bulk of them. It yielded on evaporation to dryness a sticky residue, consisting practically of sugar to the extent of 26.64 per cent. When this was incinerated there remained a small quantity of mineral matter equal to 0.10 per cent. On distillation alcohol was obtained amounting to 8.50 per cent. by weight or 10.56 per cent. by volume. The liqueur possesses a sweet but hardly an attractive taste in which the presence of peppermint is suggested. Ether did not appear to extract any substance, or at least not in any important quantity. We have not succeeded in obtaining evidence further than this that would in any sense enable us to regard this preparation as "a tonic for brain and nerve &c."

**EUCALYPTUS SOAP.**

(CURTIS AND CO., 48, BAKER-STREET, W.)

The oil of eucalyptus globulus was readily obtained from this soap on distillation. The soap lathers very freely and contains no free alkali or excess of moisture. A good proportion of the antiseptic is ingeniously incorporated into its composition, and this fact enhances its value, of course, as a cleansing agent.

**CARBOLINE.**

(HENRY ELLISON, JUN., CLECKHEATON, YORKS.)

A strongly alkaline tarry fluid, which separates into dark-brown oils on the addition of acid. With water it forms a slate-coloured emulsion which on agitation yields a soap-like lather. Although it contains tar oils and acids we did not succeed in getting any satisfactory evidence of the presence of true carbolic acid. This was searched for, more particularly as the preparation is described as non-poisonous, while it is also claimed to contain the "active principles of carbolic acid." The carbolates are, of course, highly poisonous compounds, and we should like more evidence therefore as to the non-poisonous character of the preparation. It is stated also to contain eucalyptus oil, which would account for the modified character of the smell evolved from it. Carboline being rapidly miscible with water affords probably a useful means of obtaining a plentiful supply of a powerful disinfectant at a moment's notice.

**PREPARATIONS OF THE ROYAL PERFUMERY CO.**

(NAPOLEON PRICE &amp; CO., LIMITED, 104, ALDERSGATE-STREET.)

We have received a selection of this firm's goods, which include various soaps, medicated and for toilet use, a nursery powder and a wash specially prepared for the hair. Of the soaps we have examined the following: Velveen, a white opaque soap of especial purity, free from excess of moisture and alkali, and therefore admirably adapted for all toilet requirements; real old brown Windsor, desiccated and trebly milled, containing, according to our own tests, a minimum of moisture and perfectly free from irritants; eucalyptus and pine soap, smelling pleasantly of pine and eucalyptus and yielding both bodies on distillation, although there was nothing in the mere appearance of the soap to indicate the presence of either; carbolic soap, a delicately coloured soap containing the pure acid; improved carbolic soap, a light brown soap yielding phenols on distillation; and an improved coal-tar soap, chiefly remarkable for the excellence of its colour in spite of the character of its antiseptic constituents. The nursery toilet powder was found to be free from irritants, delicately scented and to consist mainly of rice starch reduced to a fine state of division, probably by trituration. The preparation of bay rum was apparently an alcoholic extract of bay leaves. Materials of the best quality only are evidently used in the manufacture of all these products, a precaution of especial importance where articles for the toilet are concerned.

**New Inventions.****TEUFEL'S ABDOMINAL SUPPORTS &c.**

We have carefully tested the various ingenious inventions of Mr. W. J. Teufel of Stuttgart, consisting of abdominal supports, bandages, the so-called "stooop-cure" &c. It is well known that a suitable support for the abdomen in advancing pregnancy, in abdominal complaints or in corpulency is very desirable, but owing to the imperfections of most of the bandages sold it is rather difficult to get a support which is not defective in some respect; it is therefore as a rule advisable to have one properly constructed according to the special requirement of each individual case, as a bandage to fit every case requiring support is an impossibility. Mr. Teufel, recognising the truth of this statement, has divided his abdominal appliances into a series of six systems, according to the special condition; and in each series all sizes are kept in stock, so that according to the particular necessity anyone can be supplied with a support which will give the greatest amount of com-

fort and the least possible annoyance, with the most beneficial results as to the abnormal condition for which it is employed. These supports are made of various materials, as jean, white horsehair, satin, pure wool or cotton. By the addition of a specially constructed steel spring and a pad constant pressure may be made on the hypogastrium in certain uterine conditions, and a similar spring and pad are added in cases of umbilical hernia.

The "stoop-cure" is an appliance to counteract the habit of stooping in those who have weakness of the muscles of the back. It is worn under the dress without being observed, and consists of a flat backpiece containing springs lying parallel with the spine, and two moderately strong springs extending from the centre outwards to the shoulders, attached to the ends of which are two straps encircling the shoulders, so that the continuous action of the springs tends to draw backwards the shoulders. Such an appliance must be of considerable service when used in combination with exercises for improving the tone of the dorsal muscles.

The "menstrual safe-guard" is a neatly constructed arrangement for minimising the discomfort attending upon the monthly period.

These are supplied by the Teufel Remedial Appliances Company, 61, Moor-lane, London, E.C.

#### SELF-RETAINING CYLINDRICAL SPECULUM.

THE cylindrical form of vaginal speculum is the one most universally used, and Ferguson's, with mirrored surface, being cleanly, moderate in price, and affording a good view of the os and cervix, seems to be the favourite (at least with the general practitioner). The main objection to this valuable speculum is its extreme fragility, and that if left unheld after introduction it is very liable to be extruded by contraction of the vaginal walls and, if falling from the bed or couch, to be broken. The illustration represents a modification which, if the proper sized speculum be chosen, renders it self-retaining. It consists of a bulbous expansion at the outer end, which is to be introduced within the vagina; owing to its increased calibre and the sulcus around it the sphincter vaginae muscle is enabled to hold the instrument, thus setting free both hands of the practitioner. The bulbous expansion has also another advantage—that is, the concave surface forms a trough which will catch any small quantity of caustic fluids (carbolic acid, for instance) which might otherwise find its way downwards and burn or stain the external parts or the patient's clothing. This form of speculum will be found in practice a great improvement on the older form if only for the

reasons given. The makers are Messrs. Arnold and Sons, who have carried out the idea to my complete satisfaction.

Dublin.

ALEXANDER DUKE.

#### THE INVIGORATOR CORSET.

We have had submitted to us a specimen of "Rest's Patent Invigorator Corset." It claims to possess two important qualifications. First, that it tends to prevent tight-lacing, so common and so injurious; and, secondly, that it lends support to the shoulders by means of straps which cross over the shoulders and thus afford valuable assistance to persons who are weak in the chest, or who have a tendency to stoop. Tight-lacing and stooping generally go together—

what prevents the one will tend to remedy the other. We have submitted the truth of these statements to practical test and the corsets have been found to be a great comfort. They might, however, be rendered a little softer under the arms. While affording a necessary support these corsets are made of a material so pliant that they readily adapt themselves to all the movements of the body.

#### HARTMANN'S ACCOUCHEMENT OUTFIT.

EVEN in these days of aseptic midwifery it is not always easy to ensure that all the necessary articles will be ready at the time of confinement, especially in the homes of young married women, who are usually ignorant of what is needed for accouchement. The Sanitary Wood Wool Company have prepared a guinea outfit to remedy this want. It consists of a box containing various requisites, especially sheets and towlettes of various sizes made of Hartmann's antiseptic absorbent wood wool and other articles necessary for the health and comfort of the lying-in woman. We have little doubt that this supplies a want often felt equally by medical attendants, nurses and patients, and from the results of our experience of the various appliances supplied by this company we can recommend this box to all intending mothers. The "outfit" can be obtained at 26, Thavies-inn, Holborn, London.

#### A BABY-CARRIER.

SURGEONS are but too familiar with the often life-long injuries and deformities experienced by sufferers as the result of falls during infancy from the arms of nurses. The accompanying illustration depicts a simple device intended to pre-

vent such accidents; whilst it may be useful in lessening the fatigue of carrying infants and freeing the arms of the nurse for other incidental duties. As will be seen by the figure, the appliance consists of strong network attached to an eyeletted strap. This is thrown over the left shoulder and affixed to the end of the net, which is brought under the right arm by means of a hook. We draw attention to this invention, which is patented by Messrs. S. T. Matthews and Co., John Bright-street, Birmingham, as we believe it to be calculated to be of service to such as have the personal charge of infants and useful as a preventive of a class of calamities to which very young children are liable.

**NEW HOSPITAL ON BEDMINSTER DOWNS.**—The Bristol Sanitary Committee have approved of plans for a new large sanitary hospital at the Nouvers on Bedminster Downs. It will be a commodious building and provide accommodation for 100 patients and enable the medical officer of health to deal more satisfactorily with the isolation of infectious diseases. The estimated total cost of the site, buildings and drainage works will be about £30 000.

# THE LANCET.

LONDON: SATURDAY, JULY 23, 1892.

In considering the prospects of an invasion of cholera into this country it may be well to recall the past history of England as to this disease. Although cholera had long been prevalent in the valley of the Ganges, where it must be held to have its permanent centre, it did not reach this country until 1832; and seeing that this first epidemic took place before any national system for the registration of deaths had been inaugurated it is impossible now to estimate the extent of its ravages. On that occasion England became invaded by means of the sea route from the Baltic. Again, in 1849, when this country was next invaded, cholera travelled by much the same route. Having passed from Asia into Eastern Europe it crossed Russia, Prussia and Holland; it then traversed the German Ocean and first attacked our eastern coast. In 1853 a similar course of events again took place; Norway, Sweden and Denmark, with the Baltic ports of Germany, preceding our ports in so far as date of attack was concerned. On the next occasion—namely, in 1865 and 1866—a different route was followed. The line of human intercommunication between the East and Europe had undergone a change. The Cape route, with its power of extinguishing cholera as colder latitudes were reached, was giving way to a line of traffic across Egypt and by the basin of the Mediterranean; and so it came to pass that the disease first attacked certain southern towns of this country and notably Southampton. With the construction of the Suez Canal it was contended that a direct route was opened up between Calcutta and our Indian ports on the one hand and European ports on the other, and that it was by this new route that cholera would henceforth menace Europe. This view was borne out to some extent by the 1864-67 epidemic in Europe, the disease being conveyed by a French transport from Tonkin to one of the Mediterranean ports of France.

But a new danger has since then arisen for Europe. Whereas cholera formerly took a long time to travel from India to Eastern Russia across Persia or across the deserts of Turkestan, a line of railway laid down by Russia has now superseded the old trade desert routes, and this brings cholera from Bokhara, Eastern Turkestan and Northern Persia by a rapid transit right on to the Caspian Sea within a comparatively short period. Thus the danger is the greater because some of the countries traversed serve by their insubstantial state to intensify the infection; whereas by the sea route to the Mediterranean there was always a prospect that any disease on board a vessel might soon die out. It is by this new railway route through Southern Turkestan that cholera has this year reached Europe. Directly the Asiatic ports of the Caspian were attacked the disease took but a day or two before it crossed that sea to Baku and Astrakan; and then, travelling in two directions, it attacked a large number of towns south of the Caucasus and proceeded to ascend the Volga, following the

route of travel by steamer up that river. Thus, as the lines of human intercommunication have changed, and as they have been influenced by facilities for rapid traffic, so has cholera on several occasions altered its route to and within Europe, and no doubt can possibly remain that, for Europe at least, we must accept the doctrine that this disease follows those lines of travel, by sea, rail, or river, which convey men and merchandise from the East to the West.

In so far as risk to England is concerned the prevalence of cholera in Russia and its existence around Paris have both to be considered. In Russia the main prevalence at present lies in the two directions indicated. The disease has been and is widely prevalent south of the Caucasus, and thence it could most easily reach Western Europe from ports in the Black Sea and the Sea of Azov. The town of Azov and its vicinity are already infected and rumour says that cases have occurred in Odessa. The most dangerous trade between these districts and England is the rag trade, and when it is remembered that the effects, even of patients in cholera hospitals, have been sold, it requires no particular effort of the imagination to understand how contaminated clothing and linen would find its way to ports whence rags are exported to England. Hence it is that the Local Government Board have issued an order prohibiting the importation of rags into this country from the ports referred to. In a northerly direction the extension of cholera involves a double risk. From Astrakan the disease has spread up the Volga successively to Tzaritzin, Saratov, Samara, Kazan and into the province of Kostroma; it tends also to take a westerly direction, and danger may hence come both by its crossing the Prussian frontier or by its taking the Baltic route. The amount of cholera in Russia is already serious. Thus, to take only two days at the end of last week, the official, and we fear incomplete, returns record 1781 cases and 1300 deaths, and of the deaths 812 occurred in towns on the Volga. Still, at the same time, there is no immediate indication of a rapid extension westwards; and, besides this, there are grounds for hope that so far as the Baltic traffic is concerned our eastern ports may be able efficiently to cope with any emergency, and that the land route across Prussia, Belgium, Holland, Denmark &c., does not present the same favourable conditions to cholera diffusion which existed in 1854 on the occasion when the disease last reached this country by that route.

There are also certain hopeful conditions attaching to the outbreak around Paris. Whatever the source of the cholera in the Parisian suburbs it seems to lack that special aggressiveness which so commonly shows itself in a newly imported contagion. Paris itself has also remained practically immune. But as regards both this outbreak and the Russian epidemic there is the extremely uncertain element of season. A really hot August, with but little rainfall, might upset all forecasts; and the safest course for sanitary authorities to adopt will be a course of preparation for the worst that may be possible.

At this time of the year, when Londoners forget all about fogs and when London is experiencing fresh breezes and a clear atmosphere, an apology would appear to be needed for bringing to remembrance one of the worst evils of our metropolitan winter. But if to be forewarned is to be forearmed, then it

is well to give due consideration to the scheme which forms the subject of an article by Mr. L. C. D'OYLE, B.A. Camb., in the current number of the *Gentleman's Magazine*. The scheme by which this author proposes to make London smokeless is by no means novel, as a reference to the columns of THE LANCET on this subject will show; but many of the arguments urged in its favour carry with them fresh force and weight. Unquestionably the employment of gaseous fuel would be a means of obviating the evil. Why do we waste fuel, practically asks Mr. D'OYLE, and deluge the metropolis with unburnt products of combustion by burning it imperfectly and extravagantly when at properly contrived places it could be so distilled that practically all its heating power could be utilised and economically supplied in mains in the form of combustible gas? This proposal endorses once more what we have already said, that whatever may be the scheme proposed, it must necessarily be colossal in proportions and one with which only drastic legislation can be expected to deal if it is to be put into practical operation. Enjoin the people to burn smokeless fuel—or to employ smoke-consuming grates—or to use only gaseous fuel, and three proposals of an equally gigantic kind and each demanding in an equal measure, in order to secure their universal adoption, the pressure of legislative force have to be faced. The proposal to use one kind of solid fuel—e.g., anthracite—may be dismissed as obviously impracticable and then there remain practically two other proposals for consideration—viz., the use of gaseous fuel and the use of solid fuel or coal. We are justified when considering these schemes in assuming that perfect combustion and smoke-consuming appliances are available. Even supposing, to take the gaseous fuel theory first, that the task of laying down miles and miles of extra gas mains and of constructing huge retort houses has been accomplished, it is next absolutely necessary to ensure that the gas-stove is perfect in its working. Nothing can be more injurious than the imperfect products of combustion arising from faulty gas-burners, and where air is admitted, as in an ordinary Bunsen burner, the arrangement by which the exact proportion of air is regulated is very liable to get out of order unless it is frequently examined. But, as Mr. D'OYLE reasonably holds, the manufacture of gas fires as an industry is still in its infancy, and very great improvements have already been effected in their construction, and still further improvements may be confidently hoped for. On the other hand, the grate which will burn coal and burn it completely without formation of smoke or other objectionable products possesses many advantages in favour of the system of burning solid fuel. Thus, while such a grate will cost no more probably than the gas stove, it will burn the only fuel which is at the present time practically available for the purpose. The adoption of this system also will not necessitate the immense undertaking entailed by the gas-heating system; extra gas mains, for example, need not be constructed and the setting up of powerful gas-making machinery will not be requisite. Coal when properly burnt gives invisible and harmless products of combustion which differ little from those produced from coal-gas, although it is true that the "purifiers" of the gas works effect a partial reduction in the amount of sulphur in the gas. The quantity of sulphuric acid, however,

escaping from an ordinary gas burner is not so trifling as might be supposed, as may be determined by boiling water in a glass flask over a gas flame for a few hours. It will be found that the external surface of the flask after that time has become moist with sulphuric acid and intensely sour to the taste and that it acts strongly on blue litmus paper.

To the bulk of readers probably Mr. D'OYLE's strongest argument in favour of gaseous fuel would appear to be summed up in the following sentences:—"A ton of coal weighs a ton; convert it into gas and it comes at once as a decimal in gravitation and could be conveyed in mains at a very small expenditure of force per mile." Again: "A series of trunk mains running direct from the coal districts to different parts of the city could supply London with fuel in this form far cheaper than rail-roads or ships can do it at the present time in the form of coal. It is merely a question of carbonising at the mouth of the pit instead of in London, thereby saving to a great extent the expense of carting, shifting and conveying such an enormous mass as some millions of tons annually a distance of two or three hundred miles." The claim with regard to decimating the weight of coal by converting it into gas reminds us of the old catch question: Which is heavier, a pound of feathers or a pound of lead? A ton of gas weighs, of course, as much as a ton of coal, and the force required to pump gas through hundreds of miles of mains is far greater than is generally supposed. The resistance offered by so great a length of piping would be enormous and the gas would suffer considerable compression before any effect of initial pressure would be felt at the extremities of the mains. A very simple experiment suffices to illustrate this. If a person blows through a length of leaden pipe he will find that a very considerable effort is required before the air at the other end of the pipe is forced out.

Another important point which Mr. D'OYLE appears to have overlooked is that less than one-half of the coal as it is distilled at the gasworks is converted into gas. The gas produced therefore represents only at the most one-half of the fuel value of the coal as regards carbon, as more than half of it (60 per cent.) remains in the retort in the form of coke. Now in a perfect combustion-stove this would not be the case. Practically the whole of the carbon as well as the other combustible constituents of the coal would be burnt and the total heating or calorific value of the fuel be utilised.

It is evident that the smoke abatement question is still far from having arrived at a satisfactory solution; but when the difficulty shall have been successfully combated one of the biggest achievements of the age will be accomplished. One way out of the difficulty, however, seems probable; and that is, that until some other source of power becomes available, coal or solid fuel, so long as it lasts—or it may even be liquid fuel—will after all be resorted to solely for the purpose of generating and distributing a force which may at will be resolved into either radiant or calorific energy. We refer to the immense advances recently made in electricity, which promises to provide us not only with light in our homes, but also with heat that will be available for the purposes both of cooking and warming.

THE nursing profession will, we feel assured, derive much satisfaction from the way in which their calling and their work are treated by the Lords' Committee on Metropolitan Hospitals.

The remarks on this subject occupy twelve or thirteen pages of the report—a larger space than is devoted to almost any other subject in the Blue Book. There is no doubt that “nursing” is one of the burning questions of this acute age. It is said of a great living physician that when he gets ill he goes to bed and sends for a good nurse. The public are not yet quite so enamoured of the trained nurse. Her training has not yet reached that perfection at which it ceases to show itself. She still stands on her dignity a little too much, perhaps, to be altogether a *persona grata* in private houses. The patient is apt to resent her too routine and mechanical ways and her air of authority and command. The domestics are still more resentful. They declare that the trained nurse assumes airs and requires more waiting on than any other member of the house; that she is a sort of *imperium in imperio* and regards them as altogether inferior persons. Such prejudices have possibly a certain basis of reason, but they are yearly growing less and less as the training of nurses becomes more complete and nurses come to see that human nature, especially under conditions of sickness, requires a good deal of humouring. It cannot be doubted, too, that the results of medical treatment are greatly improved and enhanced by the ever-increasing frequency with which it is applied and carried out by intelligent and trained nurses, who are not affected in their ministrations by that feeling and fear which so often disable friends in the very climax of illness. We cannot but regret that nurses are still too infrequently employed. Partly from considerations of cost and partly from the existence of prejudices based on an exceptional or unhappy experience of nurses, they are still rather luxuries of the rich and of hospital patients than common blessings of the sick. The poor, too, of London and our large towns, as the Lords' Committee properly tell us, are receiving the benefit of good nursing in an ever-increasing degree at the hands mostly of ladies of cultivation and often of rank and wealth, who are appointed by the various Associations for District Nursing. From the evidence of several important witnesses it would appear that the demand for district nurses is on the increase; and Dr. BRIDGES intimated that it was in contemplation to allow boards of guardians throughout the country to establish them. One incidental advantage of an increase in district nursing would be that many cases, with this assistance, could be advantageously treated at home which otherwise would fill the scanty beds of our straitened hospitals. Still the great majority of patients of the middle and lower middle class have to do without the assistance of a regular nurse. The consequence is that the patient is longer in getting well and that his or her immediate friends, who act the nurse's part without the nurse's rest, often get laid up or become broken down. It is, however, in hospitals that the beneficent work of nurses is fully seen. It is to this work and to considerations for improving it that the Lords' Committee give so much space and, we may add, so much praise. What strikes an outside observer with surprise is the fascination which nursing seems to have for a large number of women, even in classes of society where pecuniary motives can have no force. This is a matter of common observation; but it is strikingly illustrated in the report. At the London Hospital the number of applicants for employment as nurses was 1600. Nurses are drawn from a well-educated class. Many are daughters of

professional men, merchants, farmers and tradesmen—even the nobility and aristocracy are not unrepresented in this noble class of workers—for there is no evidence in the report of ignoble work or workers. We are all familiar with old stories of cruelty in hospital nurses; but there is no reason to think that in the hospitals of London now, with a nurse to three patients and a half, and these nurses carefully selected and closely supervised by matrons of special training and large experience, any material complaints can be made. On the contrary, testimony was forthcoming of the admirable care and attention bestowed on the patients and the spirit of self-sacrificing zeal which animated the nurses. This testimony is the more creditable as their hours are still too long and their holidays and periods of relaxation too short. The work-day on an average extends from seven in the morning with short intervals for meals to nine o'clock at night. Money only is wanted to increase the proportion of nurses to the sick, but of recent years a great advance in this direction has been made. At St. Bartholomew's it has been doubled in ten years and at the London Hospital in 1880 it was 1 to 5, whereas it is now 1 to 3½. Still there is room for improvement, and when hospitals have succeeded in eliminating their unfit cases we shall expect to see such a flow of charity as will diminish by three or four hours the working day of nurses. It is gratifying to know that the Commissioners find no serious evidence of defective health in nurses as a rule.

Another satisfactory point established by the work of the Lords' Committee is the entire disappearance of friction and misunderstanding between the medical and nursing staffs. The Committee attribute this to the system by which the matron is made responsible for the efficiency and the discipline of the nurses and to the recognition of this system by the medical staff. The Committee magnify the position and the responsibility of the matron, and regard it as second in importance only to that of the medical staff, adopting apparently the strongly expressed opinions of Miss NIGHTINGALE. As the importance and position of nurses become increasingly recognised they will be expected to give more and more proof of their efficiency and training; and there seems every probability that their remuneration and their prospects will improve. In a nurse character is an important qualification. In this respect hospitals have a decided advantage over private nursing arrangements. In a hospital the nurse is under the immediate supervision of the matron and of the sisters. Virtues and faults are more quickly and easily discerned. In private practice it is difficult to get such a knowledge of the actual character of a given nurse. Faults, have to be very pronounced before patients or families will make them the subject of note or complaint to the hospital or association from which the nurse comes, and so it may happen that a faulty nurse may have a long run of employment; but the general experience of medical men will go to confirm the impression left by the report that nurses have rapidly improved in efficiency, in faithfulness and in kindness, and generally deserve the confidence of the public.

DR. SWANN has clearly demonstrated in a paper which appears on page 194 in our present number the grave results that may arise from drinking water that has been conveyed

through leaden pipes. The solvent action on lead which is specially characteristic of certain waters—notably those of the moorland supply in Yorkshire and in Devonshire—has been very carefully studied by several chemists during the last few years. Whatever way speculation may turn as to the cause of this remarkable property, it seems fairly well established that lead-dissolving waters are generally unusually soft and contain but little mineral constituents, while waters which have not the power of dissolving lead commonly contain a maximum of chalk in solution besides other mineral matter, though perhaps little organic matter. This is illustrated in a singularly conclusive experiment made by Dr. GARRETT some time ago, who found that a sample of water obtained from Mirfield, Yorkshire, notorious for its lead-dissolving powers, acted strongly on lead, but when it was mixed with New River water (a water which does not dissolve lead at all) in the proportion of 1 part of the latter to 20 parts of the former, the action on lead was entirely prevented. The addition of “hardness” to a water was recognised as a likely remedy by the subcommittee appointed by the water committee of the corporation of Sheffield in 1890. In accordance with a resolution adopted in March of that year the water supplied to the town was continuously treated with chalk, and the medical and chemical experts expressed unanimously their satisfaction with the means successfully adopted to effect the removal of the cause of complaint and also their approval of the permanent continuance of the process. The report goes on to say that, “with a view to the security of the community using the water from liability to injury from lead contamination, the process now adopted for treating that water with carbonate of lime in the form of chalk, or such modification thereof as experience may show to be an improvement thereon, be permanently continued; and that, for the more satisfactory and economical application of the process, such apparatus be provided and fitted up as will permit the addition of the material to the water in an automatic manner.”<sup>1</sup> The cases cited by Dr. SWANN, however, occurred at Batley in Yorkshire in June of the present year—that is, just two years after the above recommendation was issued. We do not gather whether the chalk remedy which has proved satisfactory in Sheffield has been tried at Batley. It seems odd if it has not, for on the face of it there is no reason why a remedy in one place should not prove also a remedy in another. Everyone will agree that the subject is serious enough to demand immediate precautionary measures, and that the evil is one to be once and for all avoided. At the Congress of Hygiene held in London last year, Dr. GARRETT, to whose investigations we have already referred, read an interesting paper on this subject, and the discussion to which it gave rise proved of an instructive character, bearing chiefly on the question of a means of prevention. Some chemists—and it is to be regretted that there were not more medical men present in this section—expressed their approval of the addition of chalk as a remedy, and one eminent expert, Professor LEHMANN of Berlin, quoted an instance in Germany where no cases of lead poisoning had occurred since this treatment had been adopted, the water having hitherto acted strongly on lead. Dr. PERCY FRANKLAND advocated

the use of carbonate of soda, while others recommended the employment of lead pipes containing 3 per cent. of tin. Lead pipes containing 3 per cent. of tin have been employed in Dublin and in Blackburn and no cases of lead poisoning, it was stated at the Congress, have since occurred, although previously to the adoption of this precaution the waters were known for their power of dissolving lead. Dr. SWANN has incidentally referred to the use of a tin-lined iron pipe. Tin, of course, is quite proof against the solvent powers of water, and if it did not possess certain other disadvantageous properties which preclude its practical employment no better material could be found. Apart from the enormous undertaking which the substitution of tin-lined pipes for those at present in use would entail, there are combined qualities possessed by lead not enjoyed by other available metals. Lead is practically the only soft metal at hand, and pipes made of it may, as is well known, be bent or adapted to almost any shape; moreover, it is easily repaired or joined. Tin, on the contrary, is hard and brittle, and when bent is liable to crack or “kink,” and where tin enters into the composition of an alloy it tends to introduce hardening qualities. It seems, therefore, that the simplest and the only practicable remedy is the one already alluded to—that is, treating the water with crushed chalk before it passes into the service pipes. Such a precautionary measure, it may be imagined, could be readily adopted by the proper authorities at the stations where the water is stored. In addition to the ordinary filter-beds of a waterworks, all that would be required would be a bed of chalk over which the water should be allowed to flow. Objections have been raised to the use of hard water for drinking purposes as likely to cause mischievous concretions in the human system; but, as a matter of fact, there is no evidence to show that such has been the case. At any rate, if hardness is regarded as objectionable, it may be got rid of by applying a simple and well-known process to the water after it has been drawn off. But of two evils the lesser should surely be chosen.

## Annotations.

“Ne quid nimis.”

### MEDICAL MEMBERS OF PARLIAMENT.

THE following is a list of members of our profession who have been elected to the new Parliament:—Charles Cameron, M.D., LL.D., will represent the College Division of Glasgow; Donald McGregor, L.R.C.P., L.R.C.S. Edin., is elected to represent Inverness-shire; Gavin B. Clark, M.D., is returned for Caithness; Robert Farquharson, M.D., F.R.C.P. Lond., LL.D., for West Aberdeenshire; Charles K. D. Tanner, M.D., for Mid-Cork; M. A. MacDonnell, M.D., for Queen’s County (Leix); J. E. Kenny, L.R.C.P., L.R.C.S. Edin., for the College Division of Dublin City; D. Ambrose, M.D., for South Louth; R. G. Price, M.R.C.S., for East Norfolk; and Sir Walter Foster, M.D., F.R.C.P. Lond., for the Ilkstone Division of Derbyshire.

### THE INTERNATIONAL MEDICAL CONGRESS OF 1893.

Now that the question as to when this great gathering shall hold its sittings has been decided in favour of “the last week of September,” 1893—a date at which, in what has been called the “non-business period of the year,”

<sup>1</sup> THE LANCET, Aug. 1st, 1891, p. 245.

Rome is a perfectly safe place of sojourn—the various sections over which the work will be distributed are proceeding vigorously with their preparations. A meeting has been held in the house of the Hon. Guido Baccelli, president of the Congress, at which a first step has been taken to constitute the committees of these sections with a view to defining their special programmes and to appointing their *personnel*. A beginning was made, appropriately enough, with the section of Sanitary Engineering, a subject of the highest importance in its bearings on State medicine, and nowhere more so than in Italy, where water-supply, drainage and the reclamation of waste malaria-breeding lands—the true *Italia irredenta*—demand immediate and effective action. The “Comitato Organizzatore della Sezione per l’Ingegneria Sanitaria” (Organising Committee for Sanitary Engineering) has thus been constituted: Signors Cadolini, Zainy, and Romanin Jacur (members of the Italian Legislature); Professors E. Gui, Gactano Bruno, and Galileo Ferraris; the engineers Finchera, Zoppi, G. de Angeli, Giachi, Fadda, Costiglia, and Lemmi; the Commendatore Bongiovannini; the Commendatore Pagliani; the Cavaliere Bentivegna; and Dr. Maggiora. To all who have interested themselves in the great undertakings of sanitary engineering in Italy during the last two decades these names are full of significance, associated as they are with the successful solution of problems that had baffled many able, energetic and hardly less accomplished predecessors. The organising committee thus appointed is now engaged in its preparatory work, prominent in which is the selection of special subjects to be introduced for discussion at the Congress. When these subjects have been definitely chosen and announced they will be entrusted to committees charged with their special study, each of which will prepare its report embodying the result of its labours. What has been achieved in the section of Sanitary Engineering will also be soon effected in the other sections, and from time to time, as their working staff and programmes are completed, we shall keep our readers informed of the progress made. In no undertaking in which her national honour has been concerned has Italy been more in earnest than in this, and she looks to its success as fraught with additional proof that she has justly won her legitimate place among the great Powers—a place attested not only by her formidable armaments on sea and land, but by her proficiency in those sciences and arts in which she once took the lead.

#### A TEACHING UNIVERSITY FOR LONDON.

As we pointed out last week, the Royal Commission, which is inquiring into this important question, has reached the most critical part of its investigations. The question of the fusion, for the purposes of scientific teaching, of some of the smaller medical schools, or of their pupils being taught science at one of the colleges or larger schools with properly-equipped scientific laboratories, is a secondary consideration; equally so are the problems of University extension teaching and of whether professors of University standing should be appointed to give lectures on subjects which a collegiate professor could not be expected to teach, or which had been made special matters of research. Already the lectures given at the Royal Colleges and at the University of London afford a precedent for such higher instruction in medicine and it would doubtless be of great value to the profession if instruction of this kind were extended. Professorships of University standing could be created for this purpose under any of the schemes, either that of the Senate of the University of London, that of the Gresham Charter, or that of the Association for Promoting a Professorial University for London. There is no practical difference between the main propositions in the earlier and

later schemes propounded by the Association. A Senate which is not composed of representatives of institutions, but which is to consist of professors and Crown nominees, can never expect to gain the adhesion of the medical schools and teaching colleges in the metropolis. It is not probable that any institution of academic rank in London would be willing to be absorbed without adequate representation on the governing body. We question even if University College (medical faculty included) is willing to be absorbed and it has been definitely stated that King's College would never agree to such a process. Other institutions, such as the larger hospitals possessing able teachers in science and good laboratories, would also refuse to submit such an integral part of their educational establishment to the absolute control of a centralised body. The medical students of London require more schools of science than one and should not be subjected to a single scientific authority, and the same applies to students in arts and science. London is too large for a centralising scheme, and some arrangement for a partial fusion among the medical schools would be far more beneficial. The fact is apparent in the documents issued by members of the Association that whilst a desire for centralisation in arts and science is obvious, the necessities of the medical schools “probably require special treatment.” The Association does not come to close quarters and tell us what treatment is recommended and how it proposes that this should be carried out. Mr. Stanley Boyd's statement would have more weight if the Executive Committee for Promoting a Professorial University for London would explain in detail, as has been done in the Gresham Charter and in the various schemes of the University of London, in what way it is proposed to translate an ideal scheme into a workable plan. With regard to Dr. Glover's letter, it may be pointed out that originally a university degree did not confer a licence to practise, but was simply an academic distinction, and there are many members of the profession who are of opinion that it would have been a wise course if the old plan had not been altered. As, however, every medical degree of a university is now a qualification, it is essential, we think, that any degrees granted by a new university in London should carry the same right as those of the older universities.

#### INCIDENTS OF THE RUSSIAN CHOLERA EPIDEMIC.

FROM all time the medical profession has been able to find among its members men distinguished no less by human fellow feeling and a high sense of personal duty than by intellectual capacity and scientific insight. We should be guilty of a widely reaching injustice were we even to allow that such men were exceptional or other than typical of their class. It is they who have earned for it that honourable position which it now enjoys in all civilised communities. It must also be admitted, nevertheless, that times of panic in the presence of uncontrollable disease, as they have exerted a depressing influence upon the mental and moral force of a population generally, have acted with a like result upon many of its healers. The plague of London acted thus as a discriminating influence. There were those who at that time bore well the crucial test of their devotion, and there were those who preferred their personal security. According to recent information members of our profession in Russia are now passing through a similar ordeal during the visitation of cholera, and details are given of a not very creditable medical exodus from the affected area. It is reassuring to learn, however, that this apparent dereliction of duty has not been entirely, if indeed it has been in any degree, spontaneous. Reports tell us of riotous disorder prevalent among the populace in Astrakhan and Saratoff, of a hospital wrecked, and of medical men and nurses shamefully maltreated. It is easy to conjecture a possible reason, which is no reason, for this extraordinary behaviour. The intractable

nature of established cholera is well known, and we may conclude that the ignorant mob have, in their impatience of the epidemic, attributed their misfortunes to the supposed incapacity of those who are labouring for their relief. This error is everywhere too common, though not everywhere equally extreme or equally disastrous. Selfishness, ignorance and ingratitude are its underlying causes. The Russian Government, it is said, has interfered to prevent the resulting exodus of practitioners, and there is therefore some ground for hope that under the control of a recognised authority we may shortly witness the signs of a clearer understanding of the position and of a more generous unity in the face of the common foe.

#### THE TREATMENT OF UNTRIED PRISONERS.

The treatment of untried prisoners is a matter to which we have on more than one occasion felt constrained to draw attention, and of late we hoped that it had received at the hands of the responsible authorities the consideration due to a matter of grave importance, affecting the comfort in a great degree and in no small measure the health of a class of persons for whose condition the community is in a special sense responsible. It would seem, however, that at Durham the accommodation afforded to prisoners awaiting trial in the precincts of the court is still conspicuously deficient. Mr. Justice Day is reported to have recently observed that it was a "sad thing that there should only be one room for male prisoners, 28 ft. long, 14 ft. wide, and 11 ft. high. Prisoners ought to be detained with convenience to themselves and convenience to society. It was sad to think that twenty or twenty-five males, many of them mere boys there for the first time, some of the men old returned convicts, were all put together, notwithstanding all the care that was taken in prisons to prevent communication." These observations need no comments to enforce them, but we trust that they will have their due effect upon those who are responsible for the state of the Durham Court House and other similar places up and down the country.

#### SUICIDE AND SMALL-POX: A QUESTION IN NOTIFICATION.

A VERY painful case, full of lessons to the profession and the public, has been the subject of a coroner's inquiry at Saffron Walden. The patient's name was Mark Chapman, aged forty-seven, living at Sewers End, a hamlet of the town. He was removed to the infectious hospital; but to make room for him two cases of scarlet fever had to be removed. The caretaker's wife was supposed to be qualified to do all the nursing, apparently including the two infectious diseases. The sanitary inspector, having removed Chapman in an ambulance, stayed with him a little time—he had been informed that he would not keep in his bed. The patient was quiet, and seemed as if he would go to sleep. The caretaker, after returning the horse which had drawn the ambulance, went to the ward and found that the patient had escaped through a space of open window about eight inches wide. He informed the police, who soon discovered the patient lying face downwards in a pond about ten yards from the hospital and presenting a dreadful appearance of skin disease. Inspector Creasy and Police-constable Lancum tried artificial respiration for some time but without success. They were warmly thanked for their exertions by the jury. The notification history of the case is more instructive than satisfactory. A medical practitioner had attended a daughter of this man for some time and allowed her to go home with an eruption which he considered chicken-pox. The symptoms had been very mild. In a fortnight a sister developed the same symptoms and then the father, when the medical attendant's suspicions of something worse were aroused. Four days after first seeing the patient he ordered his

removal to the infectious hospital, but still spoke of chicken-pox "to prevent panic." When pressed for still another case to explain the attack of the first daughter he reluctantly stated that there had been one in the grammar school. He notified Chapman's case on the Saturday. It is unnecessary to accentuate all the lessons that are contained in the above facts. As the coroner said, it is not always easy to differentiate chicken-pox and small-pox and we must make the most of this fact. Still when case follows case and an adult is attacked severely it is time to use diligence in diagnosis for the sake of the public and all concerned. We will not dwell on the sanitary prospects of a community where scarlet fever patients have to make room for small-pox without, as we understand, an interval for disinfection even if there were the materials or the nurses, which seems doubtful. We do not read a word about the revaccination of the police and other exposed persons. We trust that this crowning, if not only, protection in such circumstances has been applied with promptitude. Whenever a rash is of doubtful nature and may be small-pox all exposed persons should be revaccinated.

#### FINES FOR NON-NOTIFICATION.

The *Times* of July 20th gives particulars of charges under the Public Health Act, 1891, at the Westminster Police-court, against the Countess of Donoughmore and Dr. George Mann Carfrae. Lady Donoughmore was charged on two informations with failing to notify to the owner of a lodging-house the fact that her daughter was suffering from scarlet fever and with knowingly removing the infectious case in two cabs. Dr. Carfrae's offence was against Section 55 of the Act for failing to notify the case which he attended to Dr. Parkes, medical officer of health for Chelsea. Details were given and the facts were admitted. The defence was that her ladyship gave one of the cabmen a sovereign to have the cab disinfected and as soon as she got to her hotel she wrote to the Commissioners of Police. Dr. Carfrae said he had in the end notified; but it was shown that three days had been allowed to elapse. Mr. de Rutzen, remarking that it was of great importance that the salutary provisions of the Act should be enforced, imposed the full penalties—£10 on each of the summonses against Lady Donoughmore and 40s. in the case of Dr. Carfrae. We regret that any medical practitioner should lay himself open to so obvious a charge. Nothing would have been lost in this and in the generality of such cases by proceeding deliberately and according to law, whereas by such hasty and illegal procedure innocent people are exposed to the risk of much suffering and trouble.

#### VILLAGE SANITATION IN INDIA.

MISS FLORENCE NIGHTINGALE, with undiminished pluck and energy, and with that true womanly feeling which shines through all her noble deeds, is trying to bring home to the people of India the necessity of turning their serious attention to the sanitation of the villages. It was largely owing to the action of Miss Nightingale that the Indian section of last year's Congress of Hygiene and Demography assumed such grand proportions. In February, 1891, Miss Nightingale addressed a letter to the Poona Sarvajanic Sabha calling attention to the Congress, and emphasising the importance of India being thoroughly represented. In this letter the point is insisted upon that the native gentlemen have a duty to perform in interesting their wives in the important matter of home hygiene, and Miss Nightingale thoroughly recognises that a raising of the standard of domestic sanitation is the surest way to the real and permanent sanitary improvement of the people, and that the only way to procure pure water in country districts is to prevent the reckless fouling of wells, which, common in this country, is doubly common in India, where the poorer people

seem to be absolutely without any sense of decency or care in the elementary principles of the right bestowal of poisonous refuse. The appeal of Miss Nightingale and the other representations which were made by the Indian Committee, both privately and through the Secretary of State for India, were most successful and resulted not only in magnificent contributions to the Congress from many of the native Indian princes, but also in very thorough discussions on Indian sanitation and the establishment of a Tropical Section as a permanent feature of all future Congresses. At the close of the Congress an important memorandum was drawn up and signed by the chairman of the Organising Committee, the Secretary-General and many of the members of the Indian Committee, pointing out that the papers read at the Congress had revealed the deplorable sanitary condition of the rural villages, and urging that sanitary measures should be considered as a first claim upon the village cess or rate which is levied for local purposes. Miss Nightingale forwarded these and other documents to Lord Cross, the Secretary of State for India, and his lordship, in thankfully acknowledging the documents, promised to urge upon the Government of India and Bombay the importance of considering the representations which had been made. In another column will be found a review of the eleventh volume of the Transactions of the Congress which is devoted to Indian sanitation, and we understand that two hundred copies of it have been ordered by the India Office for distribution. Those who wish to understand the nature and the size of the sanitary problems connected with our great Eastern Empire should study the contents of this volume, to which officials and non-officials, native and English, have alike made important contributions.

#### THE MEDICAL MISSIONARY IN EAST AFRICA.

A HINDOO, jealous of the encroachments of Western civilisation on his traditional beliefs, when asked "Which of all the methods of that civilisation do you fear the most?" naturally enough evaded the question, remarking, "Why should I put weapons in the hands of an enemy?" At last he said, "We do not greatly fear the missionary schools, for we need not send our children. Nor do we fear their books, for we need not read them; nor their preaching, for we need not listen to it. But we dread the doctors and the women. The doctors are winning our hearts and the women our homes; and when our hearts and homes are won, what is there left of us?" It is, in truth, with the advent of the medical man and the trained nurse that progress has been made in the reclamation of the backward Oriental, and the annals of missionary enterprise would lose half, and more than half, of their practical interest if these two factors of their work were omitted from the record. We had recent occasion, in noticing the career of the late Rev. John Lowe, F.R.C.S. Edin., to indicate the immense leverage given to his operations by his skill in the healing art, and how the success that followed his exertions had encouraged the great medical missionary school at Edinburgh to redouble its activity and to reinforce its service by an increasingly effective contingent of medically trained workers. Nor is it less true that medicine itself is reaping the advantage of such disinterested and really philanthropic activity; and just as the discovery of America enriched our Pharmacopœia, so does the steady opening up of "Darkest Africa" and the development of its virgin resources in the vegetable and mineral kingdoms, to say nothing of its wealth in climatic situations, react for good on the means at the disposal of the profession in every branch of therapeutics. It is such considerations as these that give interest to the ceremony of the 14th inst. at Glasgow, where the memorial missionary steamer the *Henry Henderson*, built for the Church of Scotland Foreign Mission Committee, was successfully launched by its "godmother," Mrs. A. L. Bruce, daughter

of the late Dr. Livingstone. A very numerous and distinguished company, in which all ranks and professions had their representatives, assisted at the ceremony, and the chief spokesman of the occasion, Professor Henry Drummond, set forth the good service which the steamer was about to enter upon. It will enable the medical missionary to conduct operations among the Makololo and other river tribes of British East Africa, plying as it will between the Chindé mouth of the Zambesi to Port Blantyre, and touching at all the intermediate stations. Mrs. A. L. Bruce added that two other steamers, to assist the further enterprise of the mission, were in contemplation, "so as to perfect the transit service from the Chindé mouth of the Zambesi, right up the river." The friendly coöperation in this direction between the different religious sects of the mother country will soon, it is gratifying to think, be an accomplished fact—a prime agent in which desirable consummation can be no other than the increasing medical element in the undertaking—an element which ignores all differences of creed, and which, more than any other force at the service of philanthropy, can say that "its field is the world."

#### ALBINISM IN MINES.

It has long been known that animals living for generations in dark places lose the colour which is produced by exposure to the rays of the sun and assume the character of the so-called albino. It has, however, been supposed that the actual change into complete albinism is the result of generations of life in caverns, valleys and other spots from which the sun's rays have been cut off, and that by gradual change, extending from one generation to another, the races of the albino type have been developed. According to a series of observations recorded in the *Scientific American* this hypothesis must be given up, or at all events much modified. From the facts discovered during some mining operations along the famous "blue lead" near to Bangor, California, it appears that in this range of mines there was recently reopened a mine that had once been worked under the name of "the old Potter Mine" (now called after its owner, the Bishop Mine), but had been closed for thirty years. A young explorer entered a dry slope leading to a second shaft, the existence of which was unknown owing to a thick growth of brush and trees about it. In the darkness he was surprised to hear a noise arising from a number of flies that were buzzing around him. One of these he caught, and on examining it by the aid of his lantern he was astonished to find that it was of pure white colour, although its eyes were red. Soon afterwards he heard what was unmistakably the sound of a rattlesnake, and directing his light towards the place whence the sound proceeded he saw the snake so clearly that he was able to strike it down by throwing at it a portion of rock, and afterwards to kill it by crushing it with other portions of the same material. On taking this animal into the light it proved, like the flies, to be of the purest white. Professor Harlow Ballard of Buffalo, who was at the time near the mines making mineral explorations, procured the body of the snake and also several specimens of the "white flies." Within a week under the influence of sunlight the flies assumed the natural dark colour of the common house fly. The mine had originally been closed owing to flooding, but the water in it had subsided and air had been admitted, but no light. The flies, Professor Ballard believes, were the changed offspring of common flies imprisoned when the mine was closed. The snake, he supposes, had been carried down by a water current and had remained in the darkness long enough to undergo the loss of colour of its tissues which it so markedly exhibited. The observations above recorded open up the question whether we ought to consider the change of colour in the flies and the snake as due to the same cause as that

which produces the true albino. Buffon assumed that the primitive colour of every living thing in nature was white, or, to speak more correctly, that every living thing in nature was primitively colourless, and that development of colour was sequential to changes gradually induced by varieties of conditions to which things of life have been subjected in the course of ages. The after-suggestion of Blumenbach, that the peculiar colour of the eyes of albinos is due to the absence of the black pigment, exploded the hypothesis of Buffon, and afterwards led to the view generally accepted, that the white colour of the skin is brought about by a similar cause and that the loss of colouring substance is induced by a gradual and hereditary process of change. In this last record the change in the snake seems to have been direct, while in the case of the flies there was the rapid development of dark colour so soon as the influence of the sun was brought into play, as if the sun's ray had developed at once a pigmentary or colouring substance. The observations open up a new line of investigation for those who are devoted to the study of the influence of external forces on living structures and of adaptability to circumstances as part of the varied manifestations of vital phenomena that must be ever in progress in our universe.

#### ONE OF MEDICINE'S FORGOTTEN WORTHIES.

How inadequately the historian of medicine has acquitted himself of his task is impressed upon us from time to time by the publication of monographs vindicating from neglect or oblivion the good work achieved in their day and generation by inquirers, who found in the promotion of science their one pleasure and their one reward. Italians have animadverted, with something of bitterness, on the postponement of their medical pioneers to those of other countries in the apportionment of honour won in physiological and pathological fields, and they have certainly made good the claims of not a few of their compatriots to a far higher place in "the order of merit" than history has hitherto vouchsafed them. A monograph of the kind referred to has just appeared, its author being Dr. Calandruccio and its title "Agostino Bassi di Lodi, il Fondatore della Teoria Parassitaria e delle Cure Parassitiche" (Augustine Bassi of Lodi, Founder of the Parasitic Theory and of the Modes of Curing Parasitic Disease). Bassi's own countrymen had almost forgotten him; but that, as a true precursor of Cohn, of Pasteur and of Koch he was a man of powerful inductive sense and far ahead of his times, has, we think, been demonstrated by Dr. Calandruccio's work. He was born not far from Lodi in the Æmilia in 1773, matriculated at the University of Pavia, and, under that prince of physiologists, Spallanzani, devoted himself to mastering the scientific bases of medicine. An affection of the eyes caused him to make agriculture the business of his life, but without much success, blindness of a peculiarly hopeless character having supervened. But he did not abate one iota of his interest in pathological pursuits and so utilised the opportunities that his short-lived powers of vision had allowed him that, in the true scientific sense, he saw what later observers were able to verify in much more favourable circumstances, the findings of the microscope included. His agricultural occupations had interested him in silkworm disease and that peculiar phase of it known as "il calcino" engaged his earliest consideration. Having endeavoured in a multitude of ways to trace it to its cause, he tried to reproduce its characteristic forms, on the hypothesis that it developed spontaneously. Nothing daunted by repeated failure he continued his experiments and his investigations till, after nineteen years of labour and expense, he satisfied himself that he had tracked the phenomenon to its source. He published a book on the subject and showed that "il calcino" does not spring into being spontaneously; that

it is contagious; and that the principle of the contagium continues to propagate itself on the dead body of the silkworm; that the medium of contagion may be by grafting or appropriate ailments or by contact itself—all which he reinforced by experiments going to prove that the germs of the disease may be diffused by the atmosphere. The cause of the malady he defined to be a living vegetable organism—a fungus, in short—whose seeds, penetrating into the silkworm or into other insects, develop, increase and give origin to other plants, these thereafter assuming in their *ensemble* that efflorescence to which "il calcino" owes its name. Bassi describes in their diverse phases these "vegetabili minutissimi" and the conditions most favourable to their development, such as humidity, moderate heat and the like; and then he shows, step by step, how the parasitic fungus attacks the silkworms and how it multiplies itself with a fecundity quite marvellous. In view, moreover, of the readiness with which the disease may spread from locality to locality by means of these very minute germs he proceeds to recommend modes of disinfection, among which he instances the frequent cleansing and the isolation of the *locales* of the silk-worm industry; after which he advises recourse to alcohol, to boiling water, to lixiviated caustic potash, and such means of destroying the germs. This truly epoch-making work the blind, or all but blind, Bassi followed up by others in which actual research is more than replaced by acute reasoning in reply to his numerous critics. He admits a quasi-spontaneity of generation in "il calcino," which he explains as due to a pre-existence of germs which the living forms have stored up within themselves, and which in certain circumstances may develop and give rise to the disease. Bassi, moreover, anticipated the "cultures" of the bacteriologist, and from his special studies on "il calcino" he convinced himself that further knowledge in the same field will clear up marvellously the theory of contagions in general. In his latest works (1846-53) he demonstrates that all the phenomena presented by contagious maladies find their explanation in the "ipotesi parassitaria" (the parasitic hypothesis), and contends that not only plague, small-pox and rinderpest might be produced by "esseri parassiti vegetali o animali" (parasitic beings, vegetable or animal), but besides that wounds might be kept up by such parasites, of which gangrene may be regarded as a consequence. To combat these parasites Bassi counsels a recourse to fire, to boiling water, to acids, to sulphur, to the salts of mercury and recommends as a disinfecting implement the needle with which Italian children are inoculated with vaccine lymph. All which, it will be admitted, discloses an intellect much in advance of his time, justifying Dr. Calandruccio in his closing remarks: "Even the parasitic doctrine, like many other branches of the knowable (*scibile*), has had its cradle in our Italy. With us it has had its origin and its growth, while foreigners have only facilitated its wonderful acceptance and diffusion."

#### DIURETIN.

PROFESSOR DEMME, in a clinical report of the Berne Children's Hospital, mentions that he has successfully employed the so-called diuretin or salicylate of theobromine and sodium in several cases of dropsy, in which calomel and hot baths did not seem suitable and where ordinary diuretics had not proved beneficial. He finds that it may be regarded as a safe drug for children above a year old, and one that is quite free from unpleasant effects. He believes the diuretic effect is occasioned mainly by action on the renal epithelium. In scarlatinal nephritis severe dropsy coming on after the acute stage of nephritis is more easily reduced by diuretin than by any other means. In cases of mitral insufficiency, with insufficient compensation, ascites and anasarca are best combated with the help of diuretin after the compensatory disturbance has been reduced by

digitalis. As to dosage, children from two to five years of age may be ordered from eight to twenty-five grains during the day, and children of from six to ten years as much as from twenty-five to forty-five grains, in divided doses of course. The total amount for the day is generally dissolved in four ounces of water, with ten or twelve drops of brandy and forty grains of sugar. In some cases the administration was continued for some weeks without any signs of either a cumulative action or of diminished therapeutical effect being seen. In one of the cases of scarlatinal dropsy, of which details are given, the effect of diuretin was very striking. While the child was upon acetate of ammonia the urine amounted to only nine or ten ounces a day, and contained 0.15 per cent. albumen, according to Esbach's scheme of measurement, with a considerable number of granular casts and epithelium undergoing fatty degeneration. The change of treatment produced an immediate effect, the urine in the three days amounting to nearly three times the quantity previously measured and containing only half the former quantity of albumen, with very few casts, and in a week neither albumen nor casts could be found.

### THE MILITARY TOURNAMENT.

IN the notice which we published of the Military Tournament at the Agricultural Hall in our issue of June 7th, we took objection to the sleeping accommodation provided for the soldiers, to the hot and vitiated atmosphere of the hall and to the want of requisite ventilation. Tents were erected in an upstairs portion of the building and it was pointed out that such a condition of affairs was scarcely in harmony with army hygiene or complimentary to those who made the arrangements. Our attention has been recently called to the alleged occurrence of typhoid fever among some of the soldiers who were present at the Agricultural Hall on that occasion. It would be interesting to learn, presuming that the statement in question is correct, whether the occurrence of the disease among these soldiers is in any way connected with the overcrowding of the men, with the bad ventilation of the building, or with the imperfect flushing of certain of the waterclosets, particularly of those which were used by the soldiers.

### TYPHOID FEVER IN CHICAGO.

WE have received a copy of a pamphlet giving the results of an inquiry instituted by Mr. William T. Sedgwick, Professor of Biology of the Massachusetts Institute of Technology, Boston, and Mr. Allen Hazen, chemist in charge of the Lawrence Experiment Station, into the extraordinary prevalence and fatality of typhoid fever in Chicago. The paper was read in part before the American Statistical Association at Boston at the beginning of the present year. Assuming that there is no mistake about the figures and facts set forth in it, the amount of typhoid fever in Chicago has of late years assumed alarming proportions; and this state of things becomes of more than local consequence in view of the fact that the "World's Fair" is soon to be opened at Chicago. Unless measures be at once adopted and energetically applied to remove the causes of disease it is not to be expected that the consequences will be circumscribed within the limits of Chicago in 1893. For many years there has been a large amount of typhoid fever in that city; but in 1890 the death-rate from this disease rose suddenly and was still further augmented in 1891. During the latter year 1997 deaths from typhoid fever were reported in Chicago, giving a death-rate for this disease of 16.64 per 10,000 of population and a percentage of all deaths of 7.19. As compared with London, continental cities and those of the United States, the amount of typhoid fever in Chicago is very high. The typhoid fever death-rate per 10,000 inhabitants for 1881-90 was 6.75 in Chicago as compared with 1.80

in London; and in 1891 the typhoid fever death-rate in Chicago reached the proportion of 16.64 as compared with 1.40 per 10,000 in London. The general death-rate in Chicago from diseases other than typhoid fever is not excessive. The authors of the paper from which we are quoting suggest that if the total number of deaths recorded in Chicago from this disease in 1891—viz., 1997—be multiplied by ten an approximate estimate may be formed of the whole number of persons affected by it during the year; in other words, it is estimated that more than  $\frac{1}{2}$  per cent. of the population of Chicago suffered from a disease which is classed as preventable. The cause of this lamentable state of things seems to be intimately connected with that of the water-supply. It is a case of water poisoning on a wholesale scale and of long standing, but which has grown worse of late years. The water of Lake Michigan is polluted in the vicinity of Chicago by raw sewage and occasionally by the flushing of the Chicago river. We are glad to hear that the epidemic has been declining since January of the present year. It is also only right to add by way of conclusion that earnest and strenuous exertions are being made to remedy the pollution of the Chicago water-supply by some extensive works of a sanitary-engineering kind which will no doubt prove successful.

### THE BUCHANAN PRESENTATION FUND.

WE have alluded on a previous occasion to the fact that a committee, with Sir Henry Acland as chairman and Dr. Bristowe as treasurer, has been formed with the object of presenting to Sir George Buchanan, on his retirement from the post of Medical Officer of the Local Government Board, some permanent memento of the general esteem in which he is held. The conspicuous services rendered by Sir George Buchanan to public health may be said to have a world-wide reputation, and doubtless all who are interested in the cause of preventive medicine will desire to contribute their quota towards the above fund. As the committee are desirous of learning as soon as possible the amount which will be at their disposal, intending contributors should forward without delay their subscriptions to one of the secretaries—Dr. W. H. Hamer, 69, Dartmouth Park Hill, N.W.; Dr. J. C. Thresh, The Limes, Chelmsford.

### THE PATHOLOGY OF ADDISON'S DISEASE.

IN respect to the phenomena of Addison's disease and their interpretation the pendulum of pathological opinion is constantly changing its position. Broadly stated, there are two main views of its pathogeny—the one which refers the symptoms to chemical changes, and the other which claims that they may all be explained by nervous disturbance. Although it is clearly wrong to single out from all its symptoms the fact of abnormal pigmentation alone, yet, as that is the most obvious and easily noted in experimental researches, most stress has been laid upon it. As regards this single feature of the affection, the explanation has been offered, on the one hand, of its being due to the retention in the blood of products which the healthy suprarenals destroy, thus establishing a sort of parallelism between this disease and myxœdema; there is, on the other hand, no inconsiderable support to the view that pigmentation is under direct nervous control. This latter view is fully stated by Professor Raymond in a recent paper,<sup>1</sup> based on a case of lymphadenoma associated with marked melanoderma, but where the suprarenals were unaltered; whilst the great abdominal ganglia were seriously encroached upon by chronic inflammatory changes. Professor Raymond believes that in the outis there are chromatophorous cells which, like those in the frog and chameleon, are under direct nervous control, and that they yield an excess of pigment to the Malpighian layer under

<sup>1</sup> Archives de Physiologie, July, 1892.

certain conditions of nerve disorder. Pathological records afford many facts in support of this contention, and we need dwell no further upon it. Quite recently, however, some important researches upon the normal suprarenals and the urine in Addison's disease have come to the support of the chemical or humoral doctrine. Dr. F. Marino-Zuco, director of the Chémico-Pharmaceutical Institute of Genoa, has found<sup>2</sup> that normally these organs yield a notable quantity of neurine, which is also eliminated in appreciable amount in the urine in Addison's disease. In a communication by Drs. F. and S. Marino-Zuco, presented to the Academy of the Lincei by Professor Canazzaro, the subject is carried further. Experiments were first made to establish the physiological importance of the suprarenal capsules, showing that animals in which both these organs were removed did not survive, but when one only had been extirpated the animal survived and increased in weight. From fourteen to twenty-four days after the extirpation of one capsule circular slate-coloured patches were observed in the shaven skin, from which sprang tufts of blackish hair of rapid growth. In the next place they tested the action of neurine on animals, by injecting two to four cubic centimetres of a solution of 5 in 1000 into the peritoneal cavity. The daily injection of two cubic centimetres produced no constitutional disturbance, but after six to eight days small slate-coloured patches with thicker and darker hairs were visible on the abdomen, and on shaving other parts of the body the same slate-coloured patches were visible, increasing day by day. The investigators are pursuing their researches and believe that they have discovered a clue to the mechanism of the pathogenesis of Addison's disease.

#### MEANS OF ISOLATION AT BATLEY.

THE question of the provision of means of isolation for infectious diseases in the sanitary districts which make up the Dewsbury Union seems to be at a standstill. The Batley scheme of a joint hospital for a number of those authorities was practically stopped by the alternative action proposed by Dewsbury, of which nothing more seems to have been heard of late. As will be remembered Batley was recently compelled to erect a temporary hospital, but it is a building that can in no sense serve for a term of years, and it now becomes a question as to what should be done in order to meet the permanent requirements of the borough. Dr. Swann advocates the erection of a small permanent hospital for Batley purposes only, and this seems to be the most desirable procedure. It would certainly always be possible to make the hospital a joint concern with one or more of the neighbouring authorities, provided sufficient space were secured at first for further extension of buildings when that might become necessary. But one thing is certain and that is that Batley ought no longer to defer dealing with this matter in a final and efficient manner.

#### ALLEGED GAOL FEVER AT KILKENNY PRISON.

WE are indebted to Dr. C. E. James, senior surgeon to the Kilkenny County Infirmary and medical officer of H.M. Prison, Kilkenny, for the following account of the cases which have occurred there. Fourteen cases of a febrile disease, with symptoms identical with those of a case recorded by Dr. Drysdale in the *Medical Press* of the 6th inst., have occurred in the prison. The general features are acute headache and pains in back and limbs; there is a very erratic range of temperature, the maximum being usually attained on the second day; nervous symptoms and delirium are marked in some cases, absent in others; where delirium occurs it is an early symptom. It bears no relation to the temperature and sometimes is present throughout. Slow pulse (40 to 60) occurs at some period in

nearly all cases as does subnormal temperature, which is sometimes succeeded by a rise to its former height; there is no initial rigor, but sometimes a period of malaise of varying duration. All cases date the beginning of their illness to some time between June 13th and 26th, 1892. The cases occurred simultaneously in all parts of the prison among persons who had no communication with each other, two being the governor's children. The highest temperature recorded was 104°. All the usual symptoms of typhoid fever are absent. No rash, spots, iliac tenderness, specific diarrhoea or splenic enlargement are present. The disease runs a prolonged course, convalescence being slow and preceded by a stage of subnormal temperature. Of the fourteen cases eight are convalescent, four going on very favourably; one, who suffers from long-standing heart disease, is not yet out of danger, and one death in the case of a man of very intemperate habits and broken constitution has occurred. The drainage of the prison has recently been thoroughly overhauled and appears to be above suspicion. The water is derived from a well 150 feet deep, the last twenty of which are bored through solid rock, and is not contaminated by organic matter. The site of the prison is an elevated and healthy one. The hospital is a detached building and the most stringent measures of isolation and disinfection have been carried out through the whole course of the disease with perfect success, no fresh case having arisen. Similar cases have been observed in the town and surrounding district.

#### JOINT DISEASE IN HÆMATOPHILIA.

THE effusion of blood into the joints of persons with hæmorrhagic diathesis is the subject of a paper in Volkmann's clinical lectures by König of Gottingen, in which he points out that the so-called bleeder's joint is due not merely to effusion of blood into the cavity, but to irritation and a peculiar form of inflammation which leads to a permanently diseased condition, with contraction, ankylosis and other deformities. Three stages of the disease may be distinguished—the hæmorrhagic, the inflammatory and the retrogressive, the last producing conditions resembling those due to tuberculosis; the tendency to form abscesses and fistulæ which exists in tuberculosis is, however, entirely absent in hæmatophilia. As regards treatment, the less that is done the better. On no account should capital operations be attempted, their result being invariably disastrous; whereas, when absolute rest is maintained, and perhaps finally a simple puncture made into the joint, a successful result may sometimes be obtained.

#### THE SIGNIFICANCE OF FLY BITES.

WE have now reached that point in the yearly circle at which, if at any time, might have been expected a continuance of warm weather. One sure earnest of summer heat (despite the recent rains, and it may sincerely be hoped, merely temporary chilliness of northerly winds), has long been present with us in an increase in the numbers and activity of the household fly. It may appear fussy and unphilosophical to fret over this petty trouble, but we should be more than human if our patience were proof against its constant and obtrusive attentions. The sick especially have reason to complain of the annoyance it causes them. Happily, however, they are not quite without resource. The muslin fly-curtain or head covering, the hand-switch, the fan, and a variety of other contrivances attest the practical ingenuity which has been enlisted on their behalf. Not least effectual, though as simple as it is generally unobjectionable, is the device of suspending a glutinous cord above the head of the invalid. Comfort, however, is not the sole object aimed at by treatment of the fly plague. The part played by insects in the inoculation of living germs has long been recognised, and it should be remembered that even the house fly, notwith-

<sup>2</sup> Gazzetta degli Ospitali, July 9th.

standing the weakness of its mandibles, is not incapable of taking a share in this work. In THE LANCET of June 18th we showed how easily the fatal effect of the sting of a gad-fly might thus be explained. It is also a fact familiar to bee-keepers that the sting of the bee varies in severity under different conditions. May this not be attributable to the previous surroundings of the insect? We may also glean from the fact an implied lesson as to household cleanliness and as to the necessity of treating by suction, poultices, or other convenient methods even so slight a matter as an irritable fly bite.

#### DEATH OF MR. THOMAS COOK.

THE death of Mr. Thomas Cook of Leicester, at the ripe age of eighty-four, the originator of excursions by land and sea over the world, calls for a word of deep respect and regret. We sometimes complain of the restlessness of the age and its locomotive tendencies. And there is something just in the complaint. But Mr. Cook is not much to blame. His is the credit of having reduced the evils and the discomforts of travel and of having enormously contributed to the width of men's ideas of the world and of their fellow-creatures. The credit is the greater to a man who was born in a village and had to work at ten years of age for a penny a day.

#### THE STRIÆ MEDULLARES OF THE MEDULLA OBLONGATA.

It is believed by many anatomists that the striæ medullares or striæ acusticæ of the medulla are connected with the roots of the auditory nerve. Bechtzeff disputed this view some time ago on the ground that, at all events in man, the development of the striæ medullares is much later than that of the roots of the auditory nerve. He has recently published another paper in the *Meditsinskoi Obzrenie*, in which he gives an account of the course of the striæ medullares, so far as he has been able to trace them anatomically. They arise in the white substance of the cerebellum, close to the flocculus, and serve as commissural fibres for the basal portions of the cerebellum, emerging from the cortex of the convolution of the flocculus. The fibres first follow the inner basal surface of the flocculus, ascending on the margin of the cerebellum which surrounds the restiform body, and then reach the lateral margin of the fourth ventricle.

#### THE MEDICAL OFFICERSHIP OF HEALTH FOR ISLINGTON.

THE *Islington Gazette* gives a long account of the final step in the remarkable election to this medical officership of health. We cannot congratulate all the members on the discussion. Even those who were defending what they considered the reputation of the vestry from blots on its fair fame for purity of election suffered themselves to use a rudeness of speech which disfigured their cause and detracted from the weight of their arguments. The discussion took place on a report from the Public Health Committee presenting three selected candidates and recommending that one of these should be appointed. Our readers are aware that the by-law of the vestry which forbids a recent or present member of it becoming a candidate for a paid office had been twice suspended in favour of Dr. Wynn Westcott. His name was included amongst those presented in alphabetical order by the Public Health Committee. The other names were those of Mr. Alfred Edwin Harris, medical officer of health for the County Borough of Sunderland and for the Port of Sunderland, and of Mr. A. Wellesley Harris, medical officer of health for the Borough and County of Southampton. In the first division Mr. A. E. Harris had 46 votes, Dr. Wynn Westcott 43 and Mr. Wellesley Harris 23. In the final

poll between Mr. A. E. Harris and Dr. Westcott, Mr. A. E. Harris secured 47 votes and Dr. Westcott 45. So ends this important and remarkable contest. Mr. A. E. Harris is a very well known medical officer of health and his record of work in Sunderland is so full of experience and success in dealing with great epidemics and in altering a very unsatisfactory sanitary condition, that Islington may be congratulated on the appointment. We trust that Dr. Westcott's abilities will be available for the public in another sphere. His very close public relations with his fellow vestrymen, and his election by the suspension of a most wholesome by-law would not improbably have weakened his influence in Islington.

#### ABDOMINAL GUNSHOT WOUNDS.

DR. POROSKHIN describes in the *Russkaya Meditsina* a case of gunshot wound in which the bullet had injured the stomach and one kidney and the patient recovered. He leaves undecided the question whether the bowel had been perforated as well. The treatment was expectant. This case and many others described in medical literature have induced Dr. Poroskhin to teach that the treatment of abdominal gunshot-wounds in general should be expectant, with exception only of those cases in which there is hæmorrhage from the abdomen or when gases or feces escape from the wound, or when there is incipient peritonitis.

#### LEICESTER SEWAGE OPERATIONS.

ACCORDING to a report received by the Barrow rural sanitary authority from Dr. J. Turner, their medical officer of health, the village of Thurcaston is threatened with a grave nuisance, owing to the method in which the Leicester sewage is being disposed of on the adjacent land. So grave is the nuisance that a large number of letters have been addressed to the chairman of the rural sanitary authority by aggrieved persons, and Dr. Turner has advised that a notice be immediately served on the Leicester Corporation. The rural authority, after discussing the matter privately, decided to refer the whole case to the Local Government Board and to inform both the County Council and the Leicester Corporation to that effect.

#### EPICUREAN PHARMACY.

If only they were as harmless in themselves as they are worthless for any useful purpose, we might pass over unnoticed many of the æsthetic vagaries which have arisen at the prompting of a too civilised palate. Since they are not always thus impotent, however, we must be allowed a word of warning respecting them. Take, for example, the opium habit. Intended by nature and employed by man from a remote period merely as a remedial agent, we need not remind our readers how this drug has, almost within the memory of living man, usurped the place of a household luxury. When chloroform was in course of introduction it was in a somewhat similar manner adopted for a time as a kind of scientific bon-bon. It was a plaything of society, and curious tales are told of its effects in the drawing rooms of a past generation. It is asserted that some erratic epicures have more recently sought to add something to the fine native flavour of the strawberry by sprinkling it with ether. Surely the law of contrast could not be further strained or the palate of man be more grossly insulted. Better, perhaps, in taste (there is, proverbially, "no accounting for taste"), but worse by far in its unphysiological recklessness, is the practice of others, who are said to have substituted absinthe for wine at dinner. It is hardly worth our while to proclaim the self-evident fact that no process of reasoning can justify the misapplication of poisonous agents implied in each of these cases. Such experiments are doubly discreditable.

They suggest, on the one hand, a meretricious tendency to indulge in the pleasures of the palate and, on the other, a culpable indifference to the dangerous folly of playing with edged tools. These latter have their use no doubt, but not in play. Poisons have their place also, but it is in the Pharmacopœia.

#### THE CROTON WATER, NEW YORK.

THE water-supply of New York, the *New York Medical Journal* states, seems to be in a muddled condition, judging from observation and common report. From an æsthetic standpoint the unfiltered hydrant water is not attractive, and its bouquet, so to speak, does not inspire confidence. It is stated that chemical examination shows an increase of albuminoid ammonia, and that the microscope reveals the presence of vegetable matter. If this condition persists we may expect to hear of an increase in the number of cases of enteric fever among the many who use unfiltered and unboiled water.

#### TUBAL GESTATION AND OÖPHORITIS.

DR. VERTSINSKI, writing in a Russian journal on the differential diagnosis of tubal gestation and oöphoritis, calls attention to one very characteristic symptom, which had been described by Thomas as far back as 1873, had then fallen into oblivion, and was only in 1889 again thoroughly appreciated by Professor Lebedeff. This symptom is the varying size of the tumour in inflammatory conditions of the tubes and ovaries. The tumour is sometimes as large as an orange, whilst on other occasions, and often in a few days only, it is barely to be defined. This periodical variation in size is closely connected with menstruation and ovulation.

#### FOREIGN UNIVERSITY INTELLIGENCE.

*Basle.*—Drs. Siebenmann and Burckhardt have been promoted to Extraordinary Professorships.

*Buda-Pesth.*—The professorial Senate has proposed the following names for the chair of Surgery vacant by the death of Professor Lumniczner: *Primo loco*, Professor Récezy; *secundo loco*, Professor Navratil; *tertio loco*, Professor Dollinger.

*Königsberg.*—Drs. Zander and Nauwerck have been promoted to Extraordinary Professorships.

*Munich.*—Dr. Buchner, Professor of Pharmaceutical Chemistry and Director of the Pharmaceutical Institute; has retired, and Dr. Hilfer of Erlangen has been appointed as his successor.

#### DEATHS OF EMINENT FOREIGN MEDICAL MEN.

THE deaths of the following distinguished members of the medical profession abroad have been announced:—Dr. Philipp Marbreiter of Vienna, at the age of eighty-three; he was connected with the establishment of the *Wiener Medicinische Presse*.—Dr. T. G. Richardson, Professor of Surgery in New Orleans.

THE following despatch, published by *Le Temps*, completely bears out the information, diametrically opposed to that vouchsafed by the majority of our contemporaries, which we published in our issue of last week:—"Garches, July 15th, 11 A.M.—Please formally deny the news published by a newspaper of this morning's date; the health of M. Pasteur is completely re-established."

THE Royal Commission to inquire into the granting of a charter to the proposed Gresham University held a long sitting on Tuesday last in Great George-street, Westminster, Earl Cowper in the chair. The Bishop of London and the Rev. H. Wace, D.D., representing King's College, London, gave evidence in favour of the granting of a charter.

LORD SANDHURST has invited the chairmen of the boards of the general hospitals and other gentlemen interested in the subject to a conference at Spencer House, St. James's-place, which will take place at half-past three to-day (Friday), July 22nd. The meeting will be of a preliminary nature. The attention of those present will be principally directed to the possibility of the formation of a central hospital board. The subject is one of great importance and of no less difficulty, seeing that very various opinions are held by those well qualified to judge as to the best means of securing the most desirable results from the working of our noble medical charities. The proceedings, therefore, of the conference will probably occupy a somewhat lengthy period.

WE regret to announce the death of Mr. Frederick le Gros Clark, F.R.S., F.R.C.S., in his eighty-second year. He died on Tuesday at his residence, The Thorns, Sevenoaks. For many years he was surgeon at St. Thomas's Hospital and lecturer there on Surgery and Anatomy, and during the latter part of his long life he was consulting surgeon at that institution. He was the author of many works on the Anatomy and Physiology of the Nervous System, and translated in the year 1847 Dupuytren's work on "Diseases and Injuries of Bones." He was examiner for ten years to the Royal College of Surgeons, and President of the College in 1874. Mr. le Gros Clark became in 1872 a Fellow of the Royal Society.

MR. WILLIAM DALLA HUSBAND, F.R.C.S., for many years the leading surgeon in the city of York, died on July 18th in his seventy-sixth year, after a long and painful illness. Mr. Husband had filled the office of Lord Mayor of York, he was a Deputy Lieutenant for the West Riding of Yorkshire and a Justice of the Peace for York. He was consulting surgeon to the York County Hospital and had for many years been an active surgeon to the same institution. In 1868 he was appointed President of the Council of the British Medical Association. He subsequently acted as treasurer for a further period of six years.

THE colleagues of the late Sir Wm. Aitken, M.D., F.R.S., who served with him in the course of the thirty years during which he held the appointment of professor in the Army Medical School, are taking steps to erect a tablet to his memory in the chapel of the Royal Victoria Hospital at Netley.

THE thirty-fourth annual meeting of the New Sydenham Society will be held in University College, Nottingham, on Friday, July 29th, at 9.30 A.M. The business will include the consideration of the annual report, the balance sheet for 1891 and the election of officers for 1892-93.

THE appeal against the conviction in the Fulham scarlet fever case is to be heard by Sir Peter Edlin, at the Clerkenwell Sessions, to-day (Saturday), the 23rd inst. There is only one short case to be heard before it.

THE annual meeting of the Royal British Nurses' Association was held in the lecture-hall of the Royal Pavilion, Brighton, on Thursday, July 21st. Dr. Hollis, F.R.C.P., occupied the chair.

MR. DONOVAN, medical officer of health for Cork, informs us that he has traced a case of small-pox to Vosvanges, Norway, and thinks it judicious to warn English visitors of the fact.

HER MAJESTY THE QUEEN has given directions for the appointment of Dr. Francis Voley Pougnet to be a Member of the Council of Government of the Colony of Mauritius.

## NEW MEASURES AGAINST THE CHOLERA IN PARIS.

(FROM OUR SPECIAL CORRESPONDENT.)

THE present cholera epidemic already gives promise of good results. It is lamentable, but nevertheless a most positive fact, that nothing is more prolific in producing sanitary reforms than the panic engendered by cholera. In Paris, but more particularly in the suburbs outside Paris, the means to prevent the spread of disease are either inefficient or most ineffectually organised. In the suburbs of Paris, where the cholera has so far found the greater number of its victims, the authorities do not know what to do and have not the means of taking effective measures even if they were sufficiently enlightened. In Paris the authorities know what to do and have the means of doing it; but these means and this authority is divided between the Prefecture of the Seine and the Prefecture of Police. In most towns there is one mayor and he is the chief and responsible functionary. In Paris there is no mayor, but both the prefects exercise the functions of mayor, though they are irresponsible and not elected. The authority being divided rivalries have arisen between the two administrations, much to the detriment of public welfare. Seeing how dangerous this might be, more especially in the event of an epidemic, Dr. Paul Brousse, Municipal Councillor, who has recently rendered good service to the cause of sanitation by initiating and helping to organise the Workmen's Congress of Hygiene, made a proposal to centralise the sanitary services. This motion was made last February; and, as there was then no fear of cholera, the matter remained in abeyance. It needed the present epidemic to infuse vitality into the proposal, and Dr. Brousse's suggestions have now in part been realised. The proposition was printed by the Paris Municipal Council, and bears the date of Feb. 23rd last. In the preamble Dr. Brousse points out that most foreign towns and several French towns possess an autonomous, competent and responsible sanitary authority, but such an authority does not exist in Paris. There are, however, in Paris many scattered services which, if united under one single direction, would constitute a good sanitary authority.

The Article 23 of the Decree of Messidor, year 8, confers upon the Prefect of Police in Paris all the powers in respect to sanitation which the mayors of other towns possess. The Decree states: "The Prefect of Police shall maintain the salubrity of the town." This seems to render the Prefect of Police master of the situation. But on the other hand the subsequent Decree of Oct. 10th, 1859, withdrawn from this magistrate, among other administrative functions, the management of the sewers, the cleansing of the public streets, the emptying of cesspools, &c., and transferred these duties to the Prefecture of the Seine.

Thus we now find at the Prefecture of Police the Council of Hygiene and Salubrity which is a county institution, the medical sanitary inspection of women under the Contagious Diseases Act, the service of disinfection and the staff of disinfectors, the transporting of cases of infectious disease, the inspection of meat, mushrooms, &c., the veterinary service, the inspection of unwholesome industries. All these services come under the control of M. Besançon, chief of the Second Division at the Prefecture of Police, while the Municipal Laboratory is under the control of the Secretary-General of the Prefecture.

At the Prefecture of the Seine will be found all the services connected with hospitals and poor relief, all that relates to sanitation in schools, the service of disinfection—that is to say, the disinfecting stoves; the commission on unwholesome dwellings, the service for the sanitation of the interior of houses, the direction of public works and finally the statistical department.

It would be difficult to imagine a more confusing mixture. If bedding is sent to be disinfected in the stove, it is done by the Prefecture of the Seine; but the room from which the bedding has been taken must be disinfected by men sent by and working under the orders of the Prefecture of Police. The law affecting these two administrations requires thorough revision, but in the meanwhile Dr. Brousse proposes that under the Prefecture of the Seine a director of hygiene should be established, in whose hands the sanitary services

should be concentrated. The director of hygiene should be a medical man and a distinguished hygienist and should be assisted by a municipal officer, a chemist and a clerk. To this direction should be adjoined a consultative committee of hygiene, with the Prefect of the Seine as president.

This proposal, as already mentioned, met at first with but little support. Now, however, that the cholera has broken out it has been discussed on all sides, and finally M. Lozé, the Prefect of Police, has taken the bull by the horns and has himself created a central direction for sanitary matters. The decree of the Prefecture of Police is dated July 12th. The preamble says: "It is necessary to centralise the information given by the medical corps and the various administrative services on all certified cases of contagious disease, either in Paris or the department of the Seine, and to utilise to the best advantage the ambulance-waggons, the disinfecting stoves and the staff of disinfectors, so as to ensure the proper disinfection of the contaminated localities, and to coördinate and control in a united manner all the prophylactic measures taken.

### "DECREE.

"Article 1. A Permanent Committee of Hygiene, composed of the delegation of the Council of Hygiene and Salubrity of the Seine, shall be instituted at the Prefecture of Police. This committee shall consist of five members, the two county councillors belonging to the Council of Hygiene and three members annually appointed by that assembly.

"Article 2. Under the authority of this Permanent Committee, a service of information and of control for the disinfecting operations and the removal of the sick that come within the attributes of the Prefecture shall be created. This service shall consist of four medical inspectors, of whom two shall be permanent and shall act as aides or substitutes.

"Article 3. The Secretary General of the Prefecture of Police is charged with the execution of this decree.

"The Prefect of Police,

"H. LOZÉ."

This decree was no sooner issued than the Permanent Committee was at once constituted. It is composed of Dr. Léon Collin, Inspector-General of the Army Sanitary Service and member of the Academy of Medicine; Dr. Dujardin-Beaumez, chief physician at the Cochin Hospital; Dr. Proust, Inspector-General of the Sanitary Services of France; Dr. Levraud, member of the Paris Municipal Council and President of the Sanitary Commission of the Municipal Council; Dr. Paul Brousse, Municipal Councillor and member of the Sanitary Commission. The doctors who are to do the actual work of superintending the disinfection &c. are Dr. Thoinot, auditor of the Consultative Committee of Hygiene of France, and Dr. Dubief, chief of the Bacteriological Laboratory at the Cochin Hospital. The assistant inspectors are Dr. Deschamps, formerly chief of a clinique at the Faculty, and Dr. Touvenaint, laureate of the Academy of Medicine.

These appointments have given widespread satisfaction, the special competency of all the persons named being well recognised. Nevertheless, though this is a step in the right direction, the conflict between the various authorities is far from settled. Both Prefectures are, however, already working in greater harmony with each other, and we are not likely to have a repetition of former scandals. Thus, for instance, the case of the lady who was assassinated in the west-end of Paris not long ago will be remembered. She might have been saved if transported at once to a hospital. The request for an ambulance was addressed to the Prefecture of Police, whose jealous clerks would not allow the ambulance of the Prefecture of the Seine to be employed and had no ambulance at their own disposal. While the squabble between the two prefectures raged no ambulance was sent and the woman died. In another instance a contagious skin affection having broken out at a police-station the Prefect of Police was compelled to send the bedding and clothes of the policemen to be disinfected in the stoves under the control of the Prefect of the Seine. To convey these contaminated articles to the stoves the Prefecture of the Seine sent the special carts employed for this purpose. But this was more than the Prefecture of Police could bear. They were obliged to use the stoves of the Prefecture of the Seine, not having any of their own, but they could procure carts of their own. Consequently the carts specially employed for carrying contaminated objects were sent empty away, and the contaminated bedding and uniforms of the police were placed in ordinary carts. The hire of these carts had to be paid for out of the

taxes, and nobody knows whether the carts were properly disinfected afterwards. Whereas, had the Prefecture of Police condescended to utilise the carts of the Prefecture of the Seine the removal of the contaminated bedding &c. could have been performed at no cost and at no risk. These incidents will suffice to illustrate the disastrous consequences that accrue from the existence of rival authorities concerned in one and the same question.

In the meanwhile the cholera continues its slow progress, though there are more cases than is generally known or admitted. Within the walls of Paris itself twenty-seven cases are officially reported between July 11th and 15th. The proportion of deaths is of course not yet known, but in previous records it has been very high. So far, however, it is in the suburbs, and not in Paris itself, that the epidemic is doing its worst. After the lesson received in 1884 it was natural to expect that the authorities would be well prepared to meet any other similar epidemics. Such is not the case. There are better means now for coping with the danger, but these are not well organised. Fortunately, the epidemic is developing itself so slowly that there has been time to make preparation; also there is the hope that it may not become general—it certainly does not seem to have taken root in Paris itself. The cases are scattered all over the town, just as might be expected if the source of contamination was outside and had been brought in accidentally. So far therefore this fact helps to strengthen the belief that the drinking of the Seine water is the principal cause, as persons may drink that water when in the outskirts of Paris for business or pleasure and then fall ill on returning to the city.

## THE NECESSITY OF RE-ESTABLISHING THE CONTAGIOUS DISEASES ACT IN INDIA.

BY SURGEON-GENERAL SIR WM. MOORE, K.C.I.E., Q.H.P.

ALTHOUGH much has been done during recent years to improve the condition and social surroundings of soldiers and sailors we have not yet reached that problematical social millennium in which moral force shall overcome animal instincts. So long as human beings are constituted as they are physiological laws will be obeyed by the very great majority of the inhabitants of this world. For a young man who cannot marry, and who cannot attain to that exalted moral standard required for the suppression of natural instincts, there are only two ways of satisfaction—the one leads to disorders of body and mind, the other to the fearful dangers of venereal disease. In England, before the Contagious Diseases Act was passed and applied to certain military stations, the annual loss to the army owing to invaliding of soldiers for venereal disease amounted to three regiments, or, in other words, to the loss of the services of the whole force then serving in the United Kingdom for three weeks. In the navy the daily loss by men on the sick-list was 386, equal to the complement of an iron-clad. A Committee of the House of Commons reported in 1862: "The facts are so appalling that we feel it a duty to press on Government the necessity of at once grappling with the matter. Hence the Contagious Diseases Act in England. In 1866 the working of the Act was inquired into by a Committee of the House of Lords, who reported: "Prostitution appears to have diminished, its worst feature to have softened and its physical evils to have abated." In 1869 a Committee of the House of Commons reported: "The Contagious Diseases Acts have both directly and indirectly promoted the objects of sanitary and municipal police." In 1870 a Royal Commission stated that the ratio of primary syphilis among the military at protected stations had fallen from 120 per 1000 to 54, or more than one-half. The next Committee was composed of members of the House of Commons in 1879, who gave a table showing the amount of disease among newly registered women and those on the registers at nine military stations. The figures for the newly registered women are 40·2; for those on the register, 5·7. Yet all this, and much more that might be mentioned, did not prevent a section of society in England maintaining a continuous agitation against the Contagious Diseases Act, culminating in the passing of Mr. Stansfeld's motion in 1883, "That this House disapproves of the Contagious Diseases Act." As might be expected, the immediate result of the

passing of Mr. Stansfeld's Act was diminution of the number of females examined and admitted into hospital and a large increase of syphilis in the army and navy. There was also a large increase of men arriving in India on board the troopships with primary syphilis; but the House of Commons, not satisfied with the mischief done, insisted in 1888 on the abolition of the Contagious Diseases Act in India. The result is shown in the recently published report (for 1890) on the health of the army in India. Allowing for readmissions, it would appear that 500 out of every 1000 men are suffering from venereal disease. In 1890 the total number of admissions into hospital for various forms of venereal disease was 34,152 out of a total strength of 67,823. The admissions per 1000 for the whole of India in 1890 were 504. In 1887, the last year of the working of the Contagious Diseases Act, the admissions were 361 per 1000. As from that period up to the date of the last return (1890) there was an annual increase, so doubtless there has been a similar increase to the present time. We may therefore now conclude that nearly 600 per 1000 will be admitted during the year 1892 for venereal disease. In former days ague or some other tropical malady headed the lists of admissions and invaliding. Now the first place has been either usurped or nearly approached by venereal disease. For instance, in the Bombay Army in 1890 venereal disease caused 37 per cent. of the total sickness and ague 21 per cent. Of the European Army in India during 1890 it is reported that 87 per 1000 were constantly sick, against 60 per 1000 in the ten years 1870-79, and much of this increased sickness must be attributed directly or indirectly to venereal disease.

The folly of what has been done is only equalled by the absurdity of the arguments which caused it to be done. The opponents of the Contagious Diseases Act object that, as the fear of contracting disease tends to prevent men yielding to vice, it is improper to prevent such disease; that the Contagious Diseases Act increases vice by rendering it safe; that reducing the penalties of wrongdoers is playing into the hands of transgressors. But if fear of disease prevented vice, it would not prevail so extensively as it does, in London for instance, where the Act has never been applied. None but medical men fully understand the dangers of syphilis, and what is generally known is not sufficient to act as a deterrent. Moreover, the disease of soldiers and sailors is as often as not contracted when the mind is obscured by alcohol. The opponents object that examination exerts a deteriorating influence on the women. But for confirmed prostitutes no further debasement is possible. Registration and the fact of the women coming to be examined effectually prevent what used to be common enough in Bombay at least—viz., girls being practically prisoners in brothels. All are brought to light and liberty. It is also objected that the women so dislike being examined that they will not submit unless compelled to do so. Well, when the Contagious Diseases Act was abolished in Bombay and the various examination offices closed, the women went about asking where they were to be examined. It is also asserted that the system is unjust to women, being directed against one sex for the benefit of the other. It is only directed against those of the one sex who are dangerous to themselves and men. The liberty of the subject has been made an opposing point; but no person has a right to spread a contagious disease. The opponents assert that the Act does no good. Now, although the results of the working of the rules for the prevention of venereal disease for the whole of India have not been so satisfactory as could be desired, the experience of certain stations where the rules have been carefully administered shows beyond all question that with proper management a most decided impression may be made on the prevalence of primary venereal disease. I have no time to demonstrate this, but I know from experience that if the Contagious Diseases Act were well worked the amount of local syphilis may be reduced almost to *nil*. And it cannot be doubted that the care taken of diseased females must have tended to lessen venereal disease. When, as was the case in Bombay, from sixty to eighty diseased women were in the hospital who would otherwise be disseminating syphilis, such disease *must* be lessened. Whether the Act did any good or not, I think it is now tolerably certain that its abolition has done a great deal of harm. The opponents say that attendance at hospital should be voluntary. But women of the class will not voluntarily go into hospital confinement, but continue to ply their trade—some knowingly, others unknowingly—long after they are diseased. Perhaps the most absurd argument of the opponents is that syphilis

is not the destructive malady it has been asserted to be. This impression appears to arise from the fact that, except in a few cases, syphilis is not a directly fatal disease such as cholera or bad forms of fever. It is indirectly and remotely that syphilis proves so destructive, and this is not appreciated. The opponents of the Contagious Diseases Act will not believe when they are told that eye diseases, affections of the spinal cord, of the brain, of the heart, and of the blood-vessels result from syphilis, although such affections may be otherwise named. Neither will they believe that in India much of the cachexia, liver disease and fever from which the European soldiery especially suffer, is either purely syphilitic or much aggravated by syphilis, or that when an attack of sunstroke occurs it is much more likely to end in permanent disability if there is a syphilitic taint. It is also useless telling the opponents of the Contagious Diseases Act of inherited syphilis; but any large hospital, whether in England or India, daily presents numbers of children the subjects of one or other of the forms of inherited venereal disease. The advantages which arose from the Contagious Diseases Act may be mentioned as diminution of severity of disease, prevention of disease, cure of disease, social improvement by a reduction in the number of brothels and the lessening of juvenile prostitution, and opportunities afforded to women for reformation. Having had the control of the Contagious Diseases Act in Bombay for some years when surgeon-general there, I know that such advantages did, to a greater or lesser extent, accrue from the working of the Act.

I regard the abolition of the Contagious Diseases Act in India as a display of ignorance almost unparalleled. I would ask how much longer is the health of the Anglo-Indian Army to be undermined at the instance of agitators? Let us hope the Indian Army will not be called upon for service in the field while in its present deplorable condition.

## SOME MODES OF THERMAL TREATMENT AT STRATHPEFFER SPA.

BY FORTESCUE FOX, M.D. LOND.

A HIGH opinion of hot springs has been commonly held, even from the earliest times. The magnificent "Thermae" or baths established by the Romans in Italy, Gaul and even Britain show how such waters were prized by them, first as a luxury and afterwards almost as a necessity of their civilisation. Subsequently larger and more definite claims were advanced as to the medicinal and even specific virtue of this and that bath in particular diseases—claims which have been countenanced by medical opinion even to the present day. Of late years, however, an entire change of medical doctrine has taken place, arising from a more exact knowledge of the limited power of absorption possessed by the skin. Since it has been demonstrated that the sulphates and carbonates and even the chlorides and sulphides are not absorbed from their solutions by an unbroken skin, it has not been possible to believe that baths containing one or more of these ingredients possessed on that account any specific medicinal value.<sup>1</sup> Their potency, which is acknowledged, is rather of a general kind, depending on the thermal qualities in which they agree and not on the chemical qualities in which they differ. It is, however, possible that this doctrine may be pushed too far, if, for example, it is denied that chemical agencies may be competent to produce effects, stimulant or sedative, on the peripheral nerve-endings and circulation independently of absorption, or that in morbid states of the skin—eczema and ulcers, e.g.—absorption of such ingredients may take place.

The internal use of the hot spring, relying as it does on the far more active absorptive power of mucous membrane, is not likely to be challenged or regarded as "indifferent"; but in

<sup>1</sup> "In the estimate of baths therefore we may set aside the amount they contain of iron, lime, the sulphates of soda and magnesia, soda, iodine, bromine and arsenic; and as special baths we have only to consider those containing carbonic acid—the sulphur baths, the soil baths, the clinical effect of which is established and explained in a mechanically chemical manner; the moor baths (peat baths), in which special chemical agents are added to the general thermal effect; and sea baths."—Curative Effects of Baths and Waters: Braun, English Edition, p. 103

respect to their external use in the form of baths, most, if not all, of the warm mineral waters must be now regarded simply as thermal agencies. The continuous baths of Louk, the warm piscines of the Pyrenean spas, the thermal baths and douches of Aix-les-Bains and of Bath in England cannot any longer be held to depend for efficacy on their minute and various mineralisation, but on the skilled and systematic application of warmth and moisture. The old theory that "natural" or telluric heat was of a different quality from artificial heat and imparted thereby a special quality to thermal waters has no foundation in ascertained fact. It should also be observed that thermal treatment, properly so-called, includes not only the use of water and watery vapour naturally or artificially heated to the proper temperature, but also local forms, such as poultices and fomentations of every kind; and in addition the application of heat without moisture, as in the Turkish bath, and locally, as the hot sand bath and the thermal hammer.

The following observations have reference to two forms of thermal treatment in use at Strathpeffer Spa, the douche bath in various shapes and the peat bath, in both of which the principal factor is the regulated application of moist heat.

1. The douche bath: This is largely used in the ordinary form of a jet or nozzle douche as an application to the affected joints in early rheumatoid arthritis and in some cases of chronic rheumatism and gout. If serious disorganisation of the joints has not already taken place, perseverance in this treatment undoubtedly assists in restoring to the parts a healthy nutrition, whether by its effect on the circulation or nervous supply it is impossible to say. It may be worth observing in this connexion that, next to the skin itself, the joints are the most superficial portions of the body and therefore the most amenable to external influences. If changes of temperature are competent, as is the case, to produce inflammatory conditions in susceptible joints, it is not unreasonable to attribute partly to the element of temperature the beneficial effects of the douche. The low-pressure douche so largely employed at Aix-les-Bains, but until lately nowhere in this country, has been lately introduced at Strathpeffer. A large volume of water, almost without pressure and of a pleasant warmth, is continuously poured over the patient's back and shoulders whilst seated and whilst, it may be, the limbs are subjected to the ordinary (high pressure) douche. It is instructive to notice that enlightened medical opinion at the French spa is now inclined to allow that the strong hot douche is too "exciting" in many cases to which the gentle douche at lower temperatures is perfectly adapted and in which indeed it acts as a general nervous sedative. The spinal douche at Strathpeffer consists of fine jets of water in a vertical series, directed at close quarters upon the spine—the patient being comfortably seated—and given at a temperature ranging from 102° to 115°. The apparatus admits of sudden alternations with cold where desirable. The whole body may meanwhile be subjected to a low pressure or rose douche at any desired heat. The spinal douche is principally used in neurasthenia, in sluggish circulation with cold extremities and particularly in cases of congestive and nervous dysmenorrhœa. It appears to act mainly through the vaso-motor system, both on the general circulation, causing warmth and flushing of the extremities, and probably in the same manner on the pelvic and abdominal organs. In numerous cases of dysmenorrhœa the catamenia are reported as being quite painless after a course of these douches. Complete rest—lying down in an adjoining room—should always follow a bath of this kind.

2. The peat bath (moor bath): This bath is composed of disintegrated peat, or moor earth, freed from extraneous matter and mixed or churned with boiling water in a special apparatus separately for each bath. The peat itself is of a rich brown colour and is taken from deposits at an elevation of 1500 to 2000 feet. It is somewhat remarkable that this form of thermal treatment—for such in the main it undoubtedly is—although so prevalent and justly famous on the continent of Europe, was not apparently employed in this country until three years ago. It is held by competent authorities to be "less exciting" than other forms—that is to say, that it produces its effect at a lower temperature than other modes of thermal treatment. It is also further distinguished from most or all other baths by its consistence (that of a thin poultice), and especially by the state of chemical activity attributed to its ingredients. Among these ingredients, organic and inorganic, when freshly prepared at a high temperature for the bath, it is believed that chemical trans-

formations and exchanges are set going, causing a constant minute variation of temperature at the body surface. Whether or no this is a correct theory of its mode of action, the clinical facts regarding this bath remain the same. Careful observation during a long course of years at the Bohemian and other spas has established the value of the peat bath as a safe and powerful mode of thermal treatment. It is recommended more particularly in the slighter forms of spinal paralysis with motor or sensory disorder, and for promoting the absorption of exudations in the neighbourhood of joints and elsewhere.

At Strathpeffer these baths have also been used with encouraging results in chronic skin affections (eczema and psoriasis) with thickening and exudation; in simple inactivity of the skin, with a chaonically dry and sometimes cold surface; in sluggish circulation and cold extremities (a condition frequently combined with inactive skin), and in painful affections of muscles and nerves. In cases of depressed peripheral circulation patients will sometimes report, after even a single peat bath, that they feel a glow of warmth over the body to which they have been unaccustomed for years. Again, in neurotic subjects suffering from what is frequently termed "spinal irritation," with pains in the limbs, sensations of heat along the spine, posterior headache and other distresses, the peat bath is distinctly more beneficial than other forms of thermal treatment. It relieves the pains and other morbid sensations, promotes free perspiration and induces a state of calm and disposition to sleep strikingly in contrast with the excitement and restlessness sometimes caused in the same subjects by the hot douche.

In conclusion, it may be observed that the modes of treatment here described are not the only ones for which there is at present no full and sufficient explanation forthcoming. Many remedies of the greatest value have been and still are used more or less empirically, resting on experience rather than on scientific hypothesis; and among these thermal agencies, though a more complete knowledge of their *modus operandi* is to be earnestly desired, still hold the place they have held for ages in the successful treatment of many chronic ailments.

## HOSPITAL ACCOUNTS.

### [SECOND ARTICLE.]

IN our article last week upon this subject we passed in review one part of the schedule which has been prepared for use by the hospitals and showed how the statement of income might be rendered more perspicuous than it is in this form. The statement of expenditure we then reserved for subsequent criticism and to that we now turn. The principles by which we propose to test it have been already stated, but it may be convenient to restate them here. They are four—that is to say, the statement must clearly show (1) how much is annually expended on the work of the institution; (2) how that expenditure is distributed among the various departments; (3) what is the amount of the income available to meet the expenditure; and (4) from what sources that income is derived. The third and fourth of these heads have been already considered in connexion with the statement of income. The first two have now to be applied to the other (expenditure) side of the account. As to the first no difficulty arises. The importance of showing the total amount of the expenditure has been fully appreciated not only by the committee which prepared the form now under discussion, but by most other people who have taken in hand the preparation of a financial statement and hence the aggregate expenditure can very commonly be found in any of these accounts and would always be shown by a statement prepared upon the lines of the Mansion House form. The second rule is recognised to some extent, and it is upon this point that discussion must be chiefly directed. The Accounts Committee has prescribed a subdivision of the expenditure into two large groups of items: the one is called "ordinary expenditure," and covers all that is laid out upon managing the institution and maintaining its work; the other, "extraordinary" expenditure, and includes such items as building for the purpose of extension, the making of permanent improvements and the acquisition of investments for capital. To put it in a word, the "ordinary expenditure" represents expenditure pure and simple; that is to say, expenditure of the resources of the institution, whereas

"extraordinary expenditure" is expenditure only in name and represents no expenditure of resources, but on the contrary their accumulation. Such a distinction is indispensable to the production of a statement that shall not be absolutely misleading. By summing together without distinction the money expended and the money invested, it is possible to make the most thriving institution appear to be involved in financial difficulties. Attention has been recently and publicly called to instances of this particular kind of misrepresentation—instances in which hospitals that have added largely to their investments in a given year have published statements in which the expenditure is shown to be in excess of income. The general adoption of the Council's form would correct this fault, and although the desire to make an effective appeal to the charitable public may in some instances militate against the ready acceptance of a form of statement which is transparently clear, we are satisfied that upon the whole the hospitals would gain more from increased public interest and confidence than they would lose from the moderation of their demands.

This, however, is only a first step towards the elucidation of the expenditure account. A second step is taken by the subdivision of ordinary expenditure under the two heads of maintenance and administration, a division which corresponds roughly to what may be described as the expenditure upon the effective and the non-effective forces of the institution respectively. Thus "maintenance" covers the expenditure on food, drugs, rent, taxes and medical and nursing and domestic services; whereas administration covers the cost of the secretary's and collector's offices, advertisements and such-like outlay which does not directly supply the patients' needs. Here there is a manifest intention to apply a criterion of economy to the accounts of the institution, and the only question which can arise is whether the criterion is a satisfactory one, having regard to all the circumstances of the case. Our reason for thinking it unsatisfactory is that expenditure on "administration" as above defined, though one of those branches of outlay which are most apt to grow to excess, is not by any means the only one out of which extravagance can arise. It is as possible to have excessive expenditure upon the professional staff as upon the secretarial and equally possible again to pay too much for house-rent or provisions. This is to some extent recognised in the form under discussion, inasmuch as the maintenance charges are divided up under various heads representing various departments of hospital work. But at this point the scheme breaks down altogether and the distribution of the items, instead of elucidating, serves only to confuse the statement. Thus we have the full amount of the butcher's bill carried to an entry under the subhead of "Provisions," but no intimation is conveyed in what proportions the supply of butcher's meat is appropriated to the patients and to the officers by way of allowances. It may be better economy to pay liberal salaries without allowances than small salaries with them; and a statement which affords no indication of the extent to which professional services are requited by payment in kind supplies absolutely no basis of comparison between different institutions. It seems to us that the object of this final subdivision should be that of securing a clear statement of the whole cost of every several department of hospital work, whether that cost is defrayed in money or in money's worth, and that a statement of the expenditure upon salaries which is not supplemented by a corresponding statement as to the expenditure upon allowances is absolutely meaningless. This is a point which cannot be too strongly emphasised and we are therefore glad to be able to quote in this connexion the opinion of the House of Lords' Committee. They confine their observation, it is true, to the one department—namely, the out-patient department—which they consider the most important of all for this purpose and with reference to it they say (at page 97): "In the evidence before the Committee mention was made of the difficulty of ascertaining the cost of an out-patient, without which calculation any estimate of the cost 'per bed' is unreliable. The Committee do not think the difficulties insurmountable." They then proceed to sketch a plan for effecting an analysis of the accounts with this object, which, extended to other departments, would entirely accomplish the end that we have advocated. We think, therefore, that there is every reason to believe that a perfectly satisfactory statement of hospital expenditure is possible, and we hope that when a form of account is ultimately adopted this important point will receive adequate consideration.

## THE BRUSSELS OBSTETRICAL CONGRESS.

THE programme of the proceedings of this Congress was issued at the end of last week by the president, Professor Kufferath, and the general secretary, Dr. Jacobs. The sittings of the Congress will commence at the Palais des Académies on Tuesday, Sept. 13th, at 9 P.M. The Belgian Gynecological and Obstetrical Society will give a concert in honour of the members of the Congress on the Wednesday at 2 P.M. The Congress will be declared open in the presence of King Leopold II. The Exhibition will include an international display of instruments and apparatus at the Palais des Académies, and a special exhibition of specimens and instruments, contributed by the Belgian Universities, and held at the Brussels Maternité. On the Thursday, Friday, and Saturday the ordinary sittings will be held, general communications being read between ten and twelve, whilst special subjects chosen for discussion will be brought forward in the afternoon. The order of these subjects is as follows:—Thursday, Sept. 5th, Pelvic Suppuration, introduced by Dr. Segond of Paris; Friday, Sept. 16th, Extra-uterine Pregnancy, by Dr. Martin of Berlin; and Saturday, Sept. 17th, Placenta Prævia, by Dr. Berry Hart; on Thursday, at 9 P.M., the Minister of Public Works will receive the members of Congress at his official residence; on Friday, at 7 P.M., there will be a special performance at the Opera; and on Saturday evening the Belgian Gynecological and Obstetrical Society will give a banquet. Subscriptions may be sent by post-office order to the general secretary, Dr. Jacobs, 12, Rue des Petits Carmes, Brussels. After Sept. 12th they may be paid at the secretary's office. Further information will be supplied on application to the general secretary at the above address.

## MARITIME HYGIENE IN ITALY.

AN Italian correspondent writes: "I have been favoured with the following 'Ordinanza' from the Ministry of the Interior, just issued in view of the anticipated importation of cholera from the Black Sea stations. It is based on the law enacted on Dec. 22nd, 1888 (No. 5849, Series 3A), on sanitary precautions for the safeguard of the public health, and it decrees: (1) That all ships proceeding from the Black Sea ports shall be subjected to a rigorous medical examination; (2) that from these ships shall be prohibited the unloading of goods, whether linen or woollen, for personal or domestic use, which shall not have been thoroughly cleansed or previously disinfected; (3) that the harbour officials, on finding on shipboard linen or woollen goods in an uncleanly state, shall ensure before their debarkation that they be properly disinfected either by the steam apparatus provided *ad hoc*, or, if the vessel possesses no such apparatus, that they be kept for at least ten minutes immersed in water either in the boiling state or holding in solution corrosive sublimate in the proportion of 2 per 1000, with the addition of chloric acid in the proportion of 5 per 1000; (4) that the sanitary officers charged with shipboard inspections shall judge in special cases whether or not the wearing apparel of the crew or the passengers shall be subjected to the disinfecting process above mentioned; (5) that the vessels on which cases of cholera shall have been proved to have occurred during their passage or on which suspected cases of the malady shall have presented themselves, on arrival in port shall be sent to the nearest sanitary station of the island of Asinara or of the island of Poveglia, there to undergo those measures *in contumaciam* which from time to time shall be determined by the Minister of the Interior. The ships ascertained to come under the above categories shall have to make directly for the said sanitary stations before touching at any other port. The prefects of the maritime provinces of the kingdom, the dockyard authorities and the harbour officials are charged with the execution of these precautionary measures. The 'Ordinanza,' specially framed, it will be seen, to meet the danger of imported cholera from the Russian and Ottoman shores of the Black Sea, is signed by the head of the Italian Home Office (*Il Ministro dell'Interno*) his Excellency Signor Giolitti."

## METROPOLITAN HOSPITAL SUNDAY FUND.

THE following is a continued list of the contributions received at the Mansion House up to Thursday, the 21st inst., in aid of the Metropolitan Hospital Sunday Fund. The amount received up to the present is £37,500.

	£	s.	d.

## Public Health and Poor Law.

## LOCAL GOVERNMENT DEPARTMENT.

## REPORTS OF MEDICAL OFFICERS OF HEALTH.

*Thull and Goolo Port District.*—Dr. J. W. Mason's report on this port is an eminently satisfactory one, for it shows that a careful inspection of vessels is made and that when sanitary defects are discovered they are dealt with and amended. In all, 4566 vessels were thus inspected last year, and out of 169 defects 155 have already been carried out. The wholesomeness of drinking water on board receives special consideration and the emptying and cleansing of tanks are insisted on. Cases of infectious diseases are promptly removed to hospital and where necessary the crew &c. are subjected to strict medical examination. This port has close relations with the Baltic and at the present season, with advancing cholera in Russia, it is a matter of satisfaction to know that an efficient port sanitary administration is carried on under Dr. Mason's supervision.

*Newham Rural Sanitary District.*—During the past year the death-rate for this rural district was 18.5 per 1000. Notification has been in force since 1889, but, as Mr. Boustead points out, the means of isolating first attacks of infectious diseases is a necessary complement to learning of the existence of such cases. The needed hospital has, however, not yet been provided. The midden-privy system is a source of grave nuisance, and it is evidently of the utmost importance that it should be amended or abolished. From the detailed description of individual localities and villages which is given in the report, it is clear that full acquaintance with all insanitary conditions has been acquired and is maintained.

*Hatfield Rural District.*—Dr. Lovell Drage gives the general death-rate for 1891 as 13 per 1000. The subjects of epidemic influenza and diphtheria receive considerable attention in the report, certain current knowledge as to the etiology and means of diffusion of these two diseases being set out in a form that can be apprehended by the intelligent non-technical reader. As regards the latter disease, it is stated that at one and the same time diphtheria, scarlet fever, follicular tonsillitis and simple sore-throat all prevailed in one limited and defined area. Hatfield itself possesses a good water-supply and new sewerage works have been commenced. But similar works, notably as to water, are needed elsewhere and the

question of by-laws remains in an unsettled condition. Much has fortunately been done in recent years to improve dwelling accommodation.

### VITAL STATISTICS.

#### HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6471 births and 3491 deaths were registered during the week ending July 16th. The annual rate of mortality in these towns, which had been 17.1 per 1000 in each of the preceding two weeks, rose last week to 17.9: In London the rate was 18.9 per 1000, while it averaged 17.1 in the thirty-two large provincial towns. The lowest rates in these towns were 9.8 in Croydon and in Birkenhead, 10.7 in Brighton, 13.5 in Hull, and 13.6 in Oldham; the highest rates were 19.8 in Halifax, 20.0 in Salford, 21.3 in Blackburn, 21.5 in Liverpool, and 22.6 in West Ham. The 3491 deaths included 598 which were referred to the principal zymotic diseases, against numbers increasing from 477 to 503 in the preceding three weeks; of these, 260 resulted from diarrhoea, 131 from measles, 80 from whooping-cough, 60 from diphtheria, 44 from scarlet fever, 23 from "fever" (principally enteric), and not one from small-pox. No fatal case of any of these diseases was recorded last week in Brighton; in the other towns they caused the lowest death-rates in Hull, Leeds, Norwich and Derby, and the highest rates in London, Sunderland, Leicester and West Ham. The greatest mortality from measles occurred in Huddersfield, West Ham, Oldham, Halifax and Sunderland; from scarlet fever in Swansea; from whooping-cough in Huddersfield, Wolverhampton, Bolton and Burnley; and from diarrhoea in West Ham, Bristol, Preston, London and Leicester. The mortality from "fever" showed no marked excess in any of the large towns. The 60 deaths from diphtheria included 43 in London, 4 in West Ham, and 3 in Birmingham. No fatal case of small-pox was registered either in London or in any of the thirty-two large provincial towns; 17 cases of this disease were under treatment in the Metropolitan Asylum Hospitals and 4 in the Highgate Small-pox Hospital on Saturday last. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2488, against numbers increasing from 1226 to 2372 on the preceding sixteen Saturdays; 323 new cases were admitted during the week, against 331 and 301 in the previous two weeks. The deaths referred to diseases of the respiratory organs in London, which had been 185 and 170 in the preceding two weeks, further declined to 168 last week, and were 31 below the corrected average. The causes of 60, or 1.7 per cent., of the deaths in the thirty-three towns were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Cardiff, Nottingham, Oldham, Bradford, Newcastle-upon-Tyne and in ten other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham and Leicester.

#### HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined in the preceding three weeks from 19.3 to 17.6 per 1000, further fell to 17.2 during the week ending July 16th, and was 0.7 below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 13.2 in Greenock and 14.1 in Edinburgh to 18.3 in Glasgow and 20.1 in Leith. The 480 deaths in these towns included 18 which were referred to whooping-cough, 16 to diarrhoea, 13 to measles, 7 to diphtheria, 6 to scarlet fever, 2 to "fever," and not one to small-pox. In all, 62 deaths resulted from these principal zymotic diseases, against 83 and 62 in the preceding two weeks. These 62 deaths were equal to an annual rate of 2.2 per 1000, which was 0.9 below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had declined from 27 to 21 in the preceding three weeks, further fell to 18 last week, of which 9 occurred in Glasgow, 3 in Dundee, and 2 each in Edinburgh and Aberdeen. The 16 deaths referred to diarrhoea showed a marked increase upon recent weekly numbers and included 7 in Glasgow and 3 in Dundee. The fatal cases of measles, which had declined from 35 to 22 in the preceding three

weeks, further fell to 13 last week, of which 9 occurred in Glasgow and 4 in Edinburgh. The 7 deaths referred to diphtheria exceeded by 4 the number in the previous week and included 4 in Glasgow and 2 in Aberdeen. The 2 fatal cases of "fever" were both recorded in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 89 and 71 in the preceding two weeks, further declined to 65 last week, and were 8 below the number in the corresponding week of last year. The causes of 42, or nearly 9 per cent., of the deaths in these eight towns last week were not certified.

#### HEALTH OF DUBLIN.

The death-rate in Dublin, which had declined from 31.6 to 21.8 per 1000 in the preceding four weeks, rose again to 24.2 during the week ending July 16th. During the thirteen weeks of last quarter the death-rate in the city averaged 31.3 per 1000, against 18.9 in London and 17.8 in Edinburgh. The 162 deaths in Dublin during the week under notice showed an increase of 16 upon the number in the preceding week, and included 9 which were referred to measles, 4 to "fever," and not one either to small-pox, scarlet fever, diphtheria, whooping-cough, or diarrhoea. In all, 13 deaths resulted from these principal zymotic diseases, equal to an annual rate of 1.9 per 1000, the zymotic death-rate during the same period being 4.2 in London and 2.9 in Edinburgh. The fatal cases of measles, which had declined from 27 to 13 in the preceding four weeks, further fell to 9 last week. The deaths referred to "fever," which had been 1 in each of the previous two weeks, increased to 4 last week and exceeded the number in any recent week. The 162 deaths registered in Dublin last week included 31 of infants under one year of age and 28 of persons aged upwards of sixty years; the deaths of infants showed a slight further increase upon those recorded in recent weeks; while those of elderly persons showed a decline. Three inquest cases and 4 deaths from violence were registered; and 37, or more than 20 per cent., of the deaths occurred in public institutions. The causes of 13, or 8 per cent., of the deaths in the city last week were not certified.

#### CALCUTTA.

The total number of deaths registered in the town of Calcutta during the week ending May 21st was 219, against 270 and 240 in the preceding two weeks. There were 39 deaths from cholera, against 55 and 59 in the preceding two weeks; no deaths from small-pox. The general death-rate of the week was 24.4 per 1000 per annum, against 20.4, the mean of the last five years. In the amalgamated area of suburbs the total number of deaths registered during the same week was 138. There were 44 deaths from cholera, against 37 in the preceding week; no deaths from small-pox. The general death-rate of the week was 33.4 per 1000 per annum, against 28.1, the mean of the last three years. The general death-rate of the combined area was equal to 27.3 per 1000.

### THE SERVICES.

#### MEDICAL STAFF MATTERS.

THERE were several recommendations made by Lord Camperdown's Committee which we advocated at the time and to which attention may be fitly called again now when a change of Government is probably soon about to take place. The regulation by which extension of the time of a foreign service tour from five to six years was made applicable to all medical officers seems to us a hardship, nor does it appear to be an essential or economical arrangement. There are always a certain number of medical officers in India and elsewhere who are desirous of extending their periods of service in the commands in which they may happen to be serving at the time. It suits their health and their convenience; they like the climate and their work; and it is in the interest of the service that they should, as a rule, be allowed to stay on when desirous of doing so. The pay of medical officers serving in India also requires some re-adjustment, especially in the brigade-surgeon rank. The privilege of exchange should be extended to medical officers, with the approval of the Director-General, as to other branches of the service. It should not be difficult to regulate the system of exchange so as to guard it against abuse and

protect the service from financial loss. We advocated these improvements years ago and we have not seen any valid reason for changing our opinions since.

#### MOVEMENTS OF THE MEDICAL STAFF.

Surgeon-Colonel Patterson has left Hong Kong for Japan, on leave. Surgeon-Captain E. G. Browne has been granted sick leave to England, from India. Surgeon-Captain Long has arrived at Sierra Leone, for duty. Surgeon-Captain Ritchie has arrived home, on leave from Malta. Surgeon-Lieutenant Withers has been transferred to Dublin, for duty. Surgeon-Major Dorman has arrived home on leave, from Halifax. Surgeon-Major Young has reported himself for duty, at Parkhurst. Surgeon-Captain Woods has joined at Weymouth. Surgeon-Captain Blackwell has left Woolwich, on leave. Surgeon-Captain Wiles and Surgeon-Lieutenant Hughes have joined at Chester and Preston respectively from out-station duty. Surgeon-Lieutenant-Colonel Reynolds, V.C., and Brigade-Surgeon-Lieutenant-Colonel Johnson have proceeded on leave from Shorncliffe. Surgeon-Major Beamish has obtained leave from Dublin, and Surgeon-Captains Sandiford, Power and Browning have arrived at Cork. Surgeon-Major Gormley has proceeded to Limerick, from the Curragh, and Surgeon-Major O'Sullivan has joined at the Curragh. Surgeon-Lieutenant-Colonel Rooney has been promoted to the rank of Brigade-Surgeon-Lieutenant-Colonel, vice O'Farrell, retired from June 16th, and Surgeon-Captains J. G. S. Lewis and J. L. Hall have been promoted to the rank of Surgeon-Majors, from July 6th.

In consequence of the large number of officers of the higher ranks now in India, the reliefs for the coming season will, we understand, be chiefly supplied from Surgeon-Captains and Surgeon-Lieutenants. This will be greatly appreciated by the Surgeon-Majors now at home, for hitherto foreign service has pressed very heavily upon that rank, whose turn has come round much faster than that of the juniors.

#### SIR WILLIAM ATKEN'S SUCCESSOR.

We learn that the Professorship of Pathology at the Army Medical School has been conferred upon a civilian—Mr. A. E. Wright, M.B., B.Ch. Dublin., late Demonstrator of Pathology at the University of Cambridge. Opinions may differ as to whether the vacant chair of Pathology should, despite the difficulties on which we have already commented, have been filled by an army medical officer, whether of the British or Indian medical service, but there can be no difference of opinion as to Dr. Wright's eminent fitness for the post which he has accepted.

#### SURGEON-GENERAL HASSARD, C.B.

We record with much regret the death of Surgeon-General H. B. Hassard, C.B. This officer, who retired from the service in 1888, after having filled the post of principal medical officer in Ireland, had seen much service during his long and varied experience in the Medical Department. He was in receipt of a good-service pension at the time of his death. Surgeon-General Hassard served a good deal in India and had held a responsible post in the Afghan Campaign. The record of his war services embraces the following:—The Kaffir war, 1851-53; horse shot in Waterkloof (medal); the Hazara campaign of 1868, including the expedition in the Black Mountain (medal and clasp); the Afghan war of 1879-80, with the Cabul Field Force (medal); he was awarded a C.B. for his services in the last-named expedition and subsequently became the Principal Medical Officer of the Sirhind Division, and on his promotion took up the appointment of head of the Medical Service in Ireland. Surgeon-General Hassard was considered a good administrator; he was prompt and decided, possessed excellent business qualifications and was, we believe, deservedly liked and respected by those who knew him or served under him.

#### SURGEON-LIEUTENANT-COLONEL D. C. G. BOURNS, M.S.

This medical officer, who died at Oxted, Surrey, on the 9th inst., entered the army in 1864. He served in the Zulu war of 1879 (medal and clasp), in the Egyptian campaign of 1882, and was present at Tel-el-Kebir (medal, clasp and Khedive's star). On his return from Egypt he served in England some time and then went to India for a while. In September, 1890, he retired on half-pay. Of late years he had been occasionally out of health, probably attributable to malarial diseases contracted abroad. He was only forty-five years of age at the time of his death.

#### SURGEON-MAJOR F. H. MURPHY, M.S.

We much regret to announce the death of this medical

officer at Cork on the 24th ult. He became a surgeon in 1877 and a surgeon-major of the Army Medical Staff in 1889. He was the medical officer of the Royal Arsenal, Woolwich and was only thirty-seven years of age at the time of his death.

#### EUROPEAN TROOPS IN INDIA.

There can be no doubt that much more care is taken of the British soldier in India than was formerly the case. Among other sanitary recommendations the highest medical authorities went on year after year urging the importance of providing accommodation for European troops in the hills. According to the latest information from India we are glad to recognise that a remarkable change has taken place in this respect. Out of some 42,000 men in the Bengal Presidency 14,219 British soldiers, 611 women and 1392 children have been accommodated at hill stations during this hot weather. The *Pioneer* says this is double the number of twenty years ago. Enteric fever is the disease from which our soldiers suffer in India and unhappily those at hill stations are not exempt from it, although the general health of the troops is greatly benefited by residence in a hill climate.

#### THE RUPEE AND MEDICAL OFFICERS.

The rate of the exchange—which seems ever falling—and the belief that the value of the rupee has not yet reached its downward limit are becoming a very serious matter for officers and others serving in India. Instead of the proposed bi-metallism being adopted it may be definitely set aside, in which case the value of the rupee will probably be still further depreciated. It is all very well to say that the rupee still represents in India about the same value that it did, but officers serving in that country do not and cannot spend their pay there; a large number of them are married and have families to educate and support at home. To such as have to send money from India to this country the loss involved by the rate of exchange comes to a large sum in the course of the year, and Indian pay and allowances represent a nominal value which is very different indeed from the real one. Time was when service in India brought with it good salaries to cover home remittances and compensate for the risk to health and separation from family, but that time has passed away, apparently never to return. The Pagoda-tree has ceased to yield a plentiful crop; little fruit falls after much shaking; meanwhile, discontent increases among Indian officials of all sorts and the Government of India is at its wits' end to know what to do.

#### THE PARKES MEMORIAL PRIZE.

The subject for the next prize is the following: "Malarial Fevers; their Causation and Prevention." (To be illustrated, as far as practicable, from the personal experience of the writer.) Essays are to be sent in to the Secretary of the Parkes Memorial Fund, Royal Victoria Hospital, Netley, on or before Dec. 31st, 1894. Each essay to have a motto and to be accompanied with a sealed envelope bearing the same motto and containing the name of the competitor. This prize, consisting of 75 guineas and a gold medal, is open for competition to the medical officers of the Army, Navy, and Indian Services of executive rank on full pay, with the exception of the assistant professors of the Army Medical School during their term of office.

#### ARMY MEDICAL DEPARTMENT.

Surgeon-Lieutenant-Colonel James P. Rooney, F.R.C.S.I., to be Brigade-Surgeon-Lieutenant-Colonel, vice I. McD. O'Farrell, F.R.C.S.I., retired (dated June 16th, 1892).—Surgeon-Captains John G. S. Lewis and John L. Hall to be Surgeon-Majors (dated July 6th, 1892).—The Queen has approved of the retirement from the Service of Brigade-Surgeon-Lieutenant-Colonel Kenneth McLeod, M.D., Bengal Medical Establishment (dated April 16th, 1892).

#### INDIAN MEDICAL SERVICE.

Surgeon-Captain H. W. Stevenson, Superintendent of Mahableshwar, in the district of Satara, is appointed to be a Magistrate of the Second Class in that district.—The services of Brigade-Surgeon-Lieutenant-Colonel Spencer, Chief Medical Officer in Rajputana, have been replaced at the disposal of the Commander-in-Chief for appointment to the administrative medical charge of the Presidency district, vice Surgeon-Colonel Morice, who has proceeded on eight months' leave to England.—2-1st Gurkhas: Surgeon-Captain H. Smith to the officiating medical charge. 3rd Sikh Infantry: Surgeon-Captain C. H. James, from 20th Punjab Infantry, to the officiating medical charge. 2nd Punjab Infantry: Surgeon-

Lieutenant B. G. Seton to the officiating medical charge. 5th Bengal Cavalry: Surgeon-Major H. Hamilton, from 10th Bengal Infantry, to the officiating medical charge.—Surgeon-Captain A. H. Nott is appointed to act as Civil Surgeon of Hooghly.—Surgeon-Major F. C. Reeves is appointed to be District Surgeon and Superintendent of Gaol, Madura, vice Surgeon-Major W. B. Browning.—Surgeon-Captain W. H. Gray assumed charge of the civil medical duties of Dera Ismail Khan on June 4th, relieving Surgeon-Captain C. E. Sunder.—Dr. G. D. McReddie, M.D., Civil Surgeon, Hardoi, is appointed to officiate as Superintendent, Lucknow Central Prison, from date of taking charge from Surgeon-Major A. E. R. Stephens.—Brigade-Surgeon-Lieutenant-Colonel W. R. Hooper, Civil Surgeon, Lucknow, is appointed to hold visiting medical charge of the Hardoi district, in addition to his own duties, during the absence on deputation of Dr. G. D. McReddie.

YEOMANRY CAVALRY.—Middlesex (the Duke of Cambridge's Hussars): Charles Elliott Leopold Barton Hudson, Gent., to be Surgeon-Lieutenant (dated July 16th, 1892).

VOLUNTEER CORPS.—Rifle: 3rd Volunteer Battalion (the Devonshire Regiment): Surgeon-Captain F. A. Gray to be Surgeon-Major (dated July 16th, 1892).—21st Middlesex (the Finsbury): Surgeon-Captain J. Adams to be Surgeon-Major (dated July 16th, 1892).—1st Volunteer Battalion (the Prince of Wales's North Staffordshire Regiment): Surgeon-Major E. Gaily resigns his commission; also is permitted to retain his rank and to continue to wear the uniform of the Battalion on his retirement (dated July 16th, 1892).—2nd Volunteer Battalion (the York and Lancaster Regiment): Surgeon-Captain C. S. Blythman to be Surgeon-Lieutenant-Colonel, to resign his commission; also to be permitted to retain his rank, and to continue to wear the uniform of the Battalion on his retirement (dated July 16th, 1892).—3rd (Renfrewshire) Volunteer Battalion, Princess Louise's (Argyll and Sutherland Highlanders): Surgeon-Major J. Mackinlay, jun., M.D., resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the Battalion on his retirement (dated July 16th, 1892).

## THE MEDICAL BATTERY COMPANY v. JEFFERY.

### IMPORTANT JUDGMENT.

WE are indebted to the courtesy of the editor of the *Electrical Review* for the following account of a county court case which will be of interest to our readers:—

On Tuesday, at the Bloomsbury County Court, before his Honour, Judge Bacon, the claim and counter-claim in the above-named action were heard. Mr. De Witt (barrister-at-law) appeared for the company, and Mr. Lickfold (Messrs Lewis and Lewis) appeared for the defendant. The claim was £3 5s., balance of £5 5s., the price of an electric belt (Harness's patent) supplied by the plaintiff company to the defendant; and the defendant, by way of counter-claim, sought to have an I O U for £3 5s. delivered up to him, and the sum of £2 cash returned to him on the two following grounds: First, that he was induced to buy the electric belt through misrepresentation; and, secondly, that there was no good consideration for the contract into which he had entered with the plaintiff company.

Mr. De Witt said the plaintiff company carried on business at 52, Oxford-street, and were very well known, and had acquired a high reputation through their sales of electrical appliances for the cure of diseases. His Honour was probably aware of Harness's patents for electric belts and similar appliances. The plaintiffs had a branch establishment where they treated such matters as sprains, injuries to the joints, hernia and ruptures. On May 9th last the defendant, who was a bank clerk, came to the plaintiffs' place and said he thought he was suffering from a sprain. The receiving officer of the establishment at once introduced him to Mr. Simmonds, an expert in these matters in the employ of the plaintiffs. Mr. Jeffery said he had a sprain, and was afraid that it might turn to rupture. Mr. Simmonds examined him, and told him it was desirable that he should wear one of Harness's electric belts with a suspender, in order to obviate what might develop into rupture. The defendant asked the price of the belt and was told £5 5s. The defendant said he could not afford £5 5s., and Simmonds asked, "What can you pay?" The defendant said he had £2, and would pay the balance presently. Simmonds agreed to take the £2, and an I O U for the £3 5s. balance. The defendant agreed to this, and took away the belt. Nothing more was heard until early in June, when the plaintiff company received a letter from the defendant complaining of the belt, but the plaintiff company could not find the letter.

Mr. Lickfold said he was able to produce a copy which he would read. The defendant stated that after wearing the electric belt for some time sores were brought out on his body. The belt only aggravated the complaint. He had consulted a medical man and was ordered to leave it off at once, as such an article was in no way fitted for rupture. He demanded the return of his £2 and I O U for £3 5s. and threatened legal proceedings in default. In reply, the plaintiff company wrote offering to exchange the belt if it did not fit. It was their

custom to supply a good-fitting for an ill-fitting belt free of charge. On June 18th the defendant wrote saying there could be no ambiguity about his former letter and said that unless he received his £2 back and his I O U for £3 5s. was returned, he should instruct Messrs. Lewis and Lewis to proceed against them. The defendants replied, threatening legal proceedings to recover balance of account, but confirming their previous offer to exchange the belt. On the 27th Messrs. Lewis and Lewis wrote to the plaintiff company and in reply received a letter from the solicitors to the plaintiff company to the effect that proceedings had already been taken against the defendant. The defendant then filed his counter-claim.

Mr. De Witt, continuing, said the correspondence showed the position of the parties. To resume his narrative: the defendant kept the belt for one month, and when asked to pay the balance of the purchase money refused, saying he was suffering from rupture. He did not know if his learned friend (Mr. Lickfold) relied on breach of warranty, or on misrepresentation. If on breach of warranty, then Mr. Simmonds would go into the box and say he never warranted that the belt would cure the defendant.

Mr. Lickfold: I shall not say anything so absurd as that anybody warranted that the belt would cure anything.

His Honour: The counter-claim is for misrepresentation.

Mr. De Witt: And what misrepresentation?

Mr. Lickfold: The defendant called and asked to see a properly qualified man.

Mr. De Witt: I shall call Mr. Simmonds, who will tell you that in cases of hernia and rupture he is a qualified man. In cases of rupture he is a specialist, and has had, since his connexion with the plaintiff company, no less than 10,000 cases of rupture pass through his hands. In that respect he is qualified. He never said he was a qualified medical man. If the defendant had required to see a medical man, he might have seen one of the two gentlemen always on the premises. Mr. Simmonds will tell the court that on May 9th the defendant had not a rupture, but showed symptoms of what might develop into rupture and therefore it was necessary that he should have the internal pressure relieved by external support. The false representation set up here by the counter-claim is that Mr. Simmonds told the defendant he had not a rupture, and it was not until a month afterwards that the defendant learned he was ruptured. Now, a rupture may happen in a very few days.

His Honour: Yes, and sometimes in a very few minutes.

Mr. De Witt: If the defendant can establish misrepresentation there is an end to the case. But there is no misrepresentation in saying that Mr. Simmonds is a "qualified" man, and no misrepresentation in saying that on May 9th the defendant was not actually suffering from rupture.

The following evidence was then taken:—

Mr. Frederick Thomas Simmonds, examined by Mr. De Witt: I have been in the employ of the plaintiff company for nearly seven years. I have had great experience in fitting trusses and dealing with hernia and strains. During that time 10,000 cases have passed through my hands.

His Honour: How do you arrive at that estimate?

Witness: I have taken the last six months as an average and multiplied by thirteen.

Examination continued: The defendant came to our establishment on May 9th and saw one of the receiving officers. He was shown to my consulting-room. He said he had a sprain which he thought might develop into rupture. I examined him and said the hernia was incomplete.

His Honour: Then he was ruptured really?

Witness: No, not absolutely. The internal ring was disturbed, but not the external.

Examination continued: I thought there was a fear that that might happen. I recommended this electric belt in order to decrease the pressure and to give a tone to the muscles.

His Honour: Why did you not give him a truss?

Witness: He did not require one. My experience is that the wearing of a truss when not necessary is injurious.

What would be the effect of wearing a belt?—It would strengthen the walls of the abdomen.

Would not the wearing of a truss do the same thing?—No, certainly not.

Examination continued: The defendant did not take up his I O U. If he had come to us we would have changed the belt.

The defendant says the wearing of the belt was attended with painful consequences—could you have alleviated that?—Yes.

How?—That depends on what the painful consequences were.

When you fitted the belt as you fitted it, would that be attended by painful consequences?—Hardly ever.

Would the wearing of it hurt him?—Certainly not.

When the defendant was consulting you what representations did you make to him?—Nothing particular. He said he was suffering from strain. I told him if he wore the belt for a certain time the injury would probably be removed, as it had been in thousands of cases.

What did you say about your qualifications?—Nothing; he never asked me any question.

Did you say to him that you were a "qualified" man?—No; certainly not.

Did you say you believed you could relieve him of the pain from which he was suffering?—Certainly.

Was it unlikely that a rupture would develop by June 9th if he did not wear a belt?—Not at all.

Cross-examined by Mr. Lickfold: I have been employed by the plaintiff company for nearly seven years. I began treating hernia after I had been with them for about three months.

What were you before you were employed at Harness's?—I was engaged in commercial pursuits.

Have you any qualification for treating hernia?—I have studied it all my life; ever since I was nine years of age.

What was your "commercial pursuit" before you were employed by the plaintiffs?—I was a salesman in the West-end of London.

What, in the drapery line?—No, in Oriental furniture.

You do not acquire much knowledge of the treatment of hernia in selling Oriental furniture?—No.

And yet after being in the plaintiff's employ for three months you developed into this consulting person?—Yes.

You thought you had sufficient knowledge?—Yes, I had assistance from others. I am now one of the consulting officers. There are two qualified medical men on the premises daily from ten until six. I do not think it absolutely necessary to consult them in cases of hernia.

Is electricity a good thing for hernia?—Yes, in some cases. In the first or incipient form of hernia electricity would be a good thing.

His Honour: What would be its effect?—It would give a tone to the anna clos—to the weak parts.

Cross-examination continued: Hernia is a bursting of the internal coating of the stomach?—Not of the stomach, the abdomen.

And the bowel protrudes?—Sometimes. It must protrude to form a hernia.

Was there this protrusion when you saw the defendant?—There was a protrusion through the internal ring.

What would be the effect of electricity?—I cannot say, but the belt would give support.

Would the electricity heal the hernia?—No.

Would not the effect of wearing this belt be to press downwards and so aggravate the symptoms?—No, not a properly shaped belt. There would be support and the pressure would be upwards.

How many belts did you fit on the defendant?—Only one.

What skill did you show, then, in your treatment of the defendant?—I placed the defendant in a recumbent position, examined the whole of the canal and fitted a belt on him adapted to his case.

Why did you not send for one of the medical attendants?—Because in matters relating to hernia my practice is far beyond theirs.

And you do not think it necessary to consult them?—Not except in a very complicated and abstruse case; and then they generally leave it to me.

If a person came to your place and said he wanted to consult a medical man?—He would be sent to a medical man.

If he said he wanted to consult someone on hernia?—He would be sent to me.

This belt [the belt sold to and worn by the defendant] weighs between 2 lb. and 3 lb. Is that a proper belt for hernia?—Yes, for incipient hernia.

How many of these have you in stock?—Between 500 and 600.

Is there any electricity in this?—Yes.

And the patient did not require more electricity than he would get out of this belt?—He would not require an electric battery.

Do you mean to pledge your oath that there is any electrical current here?—I have no knowledge of electricity.

Then why did you sell an electric belt and charge £5 5s. for it?—I have not a large knowledge of electricity, but I have a sufficient knowledge of its physiological effects to know that it would be useful.

Do you pledge your oath that the patient would get a serviceable amount of electricity from this belt?—Yes, certainly. The moisture of the body would complete the circuit.

Did not the defendant when he called on you ask for a truss?—No.

How much would a truss cost?—From 7s. 6d. to 12s. 6d.

If you merely intended to support the parts you could get as much support from a plain belt as from this belt?—Certainly.

Then why did you sell him this?—He wanted a tonic to the local parts.

And so you thought you would give him this affair?—Yes. I did not give the defendant his bill; it was brought to him.

What is the intrinsic value of this thing?—I do not know.

About 16s.?—I have no idea. I have nothing to do with the cost of the goods.

You are above that sort of thing?—A little above it.

Re-examined: These belts are patented by Mr. Harness?—Yes. Harness has a large number of patents. I am not an electrical expert, and I do not know the mode in which the electrical current passes.

This was the plaintiffs' case.

Mr. Lickfold, addressing the Court, said the defendant was a cashier in the Union Bank, and having, as he feared, ruptured himself, his attention was attracted to an advertisement calling attention to the Electropathic and Zander Institute, 62, Oxford-street, where medical advice was given gratis. He asked to see a medical man.

He saw Mr. Simmonds and told him he was suffering from rupture. Mr. Simmonds examined him and told him he was not so suffering and added: "You must have one of our belts and that will set you right."

The defendant was fitted on and took a belt costing £5 5s. Instead of doing good, the belt chafed the skin and caused an eruption and the illness was so aggravated that the defendant consulted a medical man, Dr. Rowntree.

After going through the facts, which he would prove in evidence, the learned gentleman submitted that there had been misrepresentation in this case, because Mr. Simmonds was not a qualified man, and because he misled the defendant by telling him that he was not suffering from hernia when he was so suffering. Then the defendant was entitled to have his money and I O U returned to him as he had not received any good and proper consideration for his money.

The defendant, Mr. D. Jeffery, in examination-in-chief, said in consequence of what I read in an advertisement I called at Harness's place, 62, Oxford-street. I saw a porter and said I wanted to see a qualified gentleman to inform me if I was ruptured or not. I was introduced to Mr. Simmonds. I told him I feared I was ruptured and wanted a truss. He examined me and said I was not suffering from hernia, and if I used one of Harness's belts I should derive benefit from it. He said he would recommend me an electric belt and I should soon be all right.

He fitted one on me. I dressed. Someone else presented me with a bill for £5 5s. I only had £2 with me and the cashier said my I O U for £3 5s. balance would do. I was very pleased at being told that I was not ruptured. I wore the belt for some time and it gave me great pain. There was a downward pressure and a lump formed in my groin; an external sore also formed. When I took off the belt I felt relief.

I consulted Dr. Rowntree. I left off the belt entirely and wore a truss, which cost 12s. 6d. I am much better now. The doctor told me I was ruptured and had been so for some time.

Cross-examined by Mr. De Witt: I have been a bank clerk for twenty-nine years. I told Mr. Simmonds I feared I was ruptured. He examined me carefully, I believe. I do not think he wilfully intended to do me any mischief. I saw Dr. Rowntree on May 23rd. Between May 9th, when I called at the plaintiffs' establishment, and May 23rd, when I saw the doctor, I had been attending to my business. I wore the belt for more than a week. I got so bad that when I moved I was

in excruciating pain. I did not ask the price of the belt before it was fitted on, and had I known it was £5 5s. I would not have purchased it.

What is the false representation you complain of?—That Simmonds told me I was not ruptured.

You complain that you were induced to part with £2 by a false representation. What was the false representation?—I went for a truss. Simmonds assured me that I did not want a truss, and that it was not ruptured.

Re-examined: I got worse whilst wearing the belt.

Mr. William George Rowntree, L.R.C.P., examined, said: On May 23rd Mr. Jeffery called on me at my house. I examined him and found that he was suffering from rupture. There was no doubt about the nature of his suffering. I have examined the belt and I say, if it was fitted tight on a patient suffering from rupture it would aggravate the complaint. I have heard the defendant's evidence as to the swelling in the groin, and I think that that swelling had existed for some time previous to my seeing him.

Would the belt produce that swelling?—Not unless there was previous hernia.

Would this belt be of any use to the defendant?—Not of the slightest use. I recommended a truss and the patient is getting better.

Cross-examined by Mr. De Witt: Rupture may come on in a few minutes, but there are generally previous symptoms well known to medical men. I undertake to say that the defendant was suffering from rupture on May 9th. I believe the rupture was of one month's duration at least—and from the symptoms which the defendant described to me, it might have been of three months' duration.

Mr. Tom Ernest Gatehouse, examined by Mr. Lickfold, said: I am an electrical and consulting engineer of twenty-two years' standing.

Have you examined this belt (produced and handed to witness)?—Yes.

And what do you say of its electrical powers?—I say that it has not any, and that it is utterly useless.

Why do you say so?—Because I have tested it.

There is something in it—some zinc and copper—and why do you say it is useless as an electrical appliance?—Because as the belt stands it cannot generate any electricity at all.

His Honour: You have heard the witness (Mr. Simmonds) say that the moisture of the body, acting on these bits of zinc and copper, would complete the circuit. Have you tried it in this way?

Witness: Yes. The moisture of the body is supposed to act chemically on these metals. Your Honour is acquainted with the old schoolboy experiment of putting half-a-crown under and a penny above the tongue, and on bringing the two metals in contact little flashes of light appear before the eyes of certain people.

His Honour: I did not know about the light. I thought you could only taste.

Witness continuing: The moisture of the body would be sufficient to set up a current between two dissimilar metals, but you must have a complete circuit. If I place one half of this belt on my stomach and the other half on my back, I have the elements for a galvanic battery, but there is no completion of the electrical circuit.

His Honour: The witness says the circuit is completed by the action of the moisture.

Witness: That is the internal, and not the external circuit.

His Honour: Why would not a body touched back and front and all around complete a circuit?

Witness: As this belt was worn it never produced a trace of electricity. This morning I made an experiment with this belt, so as to produce a small quantity of electricity. I took salt water and moistened the two parts, and then I connected the copper and zinc with a galvanometer, and so I got a slight deflection of the needle of about fourteen degrees. I then put the belt on my legs and on my arms and the deflection was not in the slightest degree altered. That shows that when these belts are worn by any patient no electricity passes through the body in any way whatever, but only along the webbing of the belt and over the skin surface. Electrically, these things are useless.

Mr. Lickfold: Then you say this belt electrically is absolutely a useless article?

Witness: Yes.

Cross-examined by Mr. De Witt: Zinc and copper are used in generating electricity.

Do you say that this belt would produce no current at all?—Not as the defendant wore it. The circuit was not completed. I saturated this belt with salt water, and then I got a small electrical current. I say there is a current, but the current, if properly connected up, will not go through the body—it is the webbing and skin and not the body which forms the internal circuit.

This concluded the evidence.

Mr. De Witt contended that though there might have been an error in judgment on the part of Mr. Simmonds, there had been no wilful misrepresentation, such as, according to the ruling in the case of Peck v. Derry, would entitle the defendant to have his contract rescinded and his money returned. He also submitted that there had been no failure on the plaintiffs' part to give the defendant consideration for his money.

His Honour, in giving judgment, said: In this case the plaintiff sues for the balance of the purchase money of an electrical appliance, and the defendant by his counter-claim says: I want to get back the money which I paid on account, either on the ground that I bought it on the misrepresentations made to me by your agents, or on the ground of a failure of consideration. The defendant has been taken in in the sense that he has been persuaded to buy something utterly useless. It is not every such case which will entitle the purchaser to avoid his purchase and have back the purchase money, but there are cases in which the purchaser is entitled to avoid his contract. After referring to the case of Peck and Derry, His Honour continued: I think it is clear, on the evidence, that the defendant went to the plaintiffs' establishment and asked to see a qualified doctor. That was uncontradicted. The defendant has shown that the gentleman whom he saw (the gentleman who calls himself an "expert," a gentleman without any medical education, or education in this matter, except having studied the best works on the subject since he was nine years of age), and when he asked for a truss recommended him something which he said was better. The defendant has shown that this gentleman told him he was not suffering from rupture, but only from the beginning of rupture. I have no doubt from the evidence Mr. Simmonds said to the defendant: "I

am happy to tell you you are not ruptured." But that was not the fact; the defendant was ruptured, as I cannot help believing from the evidence of Dr. Rowntree, who says: "From my observation, and from the symptoms described to me by the defendant, I am satisfied that the rupture had existed three months before I saw him on May 23rd." Then was the thing which the defendant received the thing which he asked for? I will not enter into the merits of an electrical appliance which I do not understand. Mr. Gatehouse's evidence as to the electrical volume may be right or wrong—I do not know; but this (this belt) is the thing put on the man when he was ruptured, and the man was persuaded to buy it upon the representation that he was not ruptured. He went for a truss. He was told, "You do not want a truss." This is a representation made by a man who had not taken the trouble to qualify himself, and who ought not to have made any representation at all. That was the representation which led to the contract—a contract without any good of any sort to the defendant, and it must be avoided. There must be judgment for the defendant on his counter-claim, and his £2 must be returned to him.

Mr. Lickfold applied for costs on the higher scale.  
His Honour refused the application. Judgment accordingly.

## Correspondence.

"Audi alteram partem."

### A TEACHING UNIVERSITY FOR LONDON.

To the Editors of THE LANCET.

SIRS,—In your issue of July 16th you publish an annotation upon "A Teaching University for London," which contains evidence that upon some points the proposals of the Association for Promoting a Professorial University for London have not been fully understood. I have myself no right to speak authoritatively for this Association; but it has been my duty to inquire into their views, and, as expounded to me by the secretary and other members of the Association, they differ very markedly from what you state them to be. I am not at all surprised that you have been misled, for I have not yet met the man who, without skilled assistance, has succeeded in appreciating the true meaning of the proposals of the Association. They are exceedingly sketchy, particularly with regard to medicine—rightly so, I should say. The scheme was foreshadowed in the fourth proposal of the Association for Promoting a Teaching University for London (February, 1886); its main features were clearly enunciated by Professor Ray Lankester in his evidence before the Royal Commission (June 23rd, 1888); and now it appears again with much wider support. Practically this scheme comes from the faculties of Arts and Science, and it is a bold move to obtain for London, not at once, but in the course of time, the advantages of a great university, such as those of Berlin or Strassburg. There are apparently two things chiefly which attract great minds—viz., large emoluments and great opportunities for work and teaching. Neither the endowment of the chairs in University College and King's College, or the perfection of their laboratories, or the size or quality of their classes, is sufficient to enable these institutions to obtain and to retain the services of the greatest teachers and workers in the various subjects. The two colleges say in the Gresham Charter—"Give us the power of granting degrees to students whom we have taught and our benches will soon fill, as also will our pockets; then we shall be able to improve our laboratories and to pay the best teachers, and all will go well with us; there is nothing in the Gresham Charter to prevent our blending as closely as we like, to prevent our establishing intercollegiate lectures &c." The promoters of the professorial scheme reply that in the Gresham Charter there is not the least guarantee that there will be any common action between the two colleges; on the contrary, the Senate consists very largely of the representatives of institutions—put there, confessedly, to "guard the interests" of the institutions—and this can hardly be taken as a good start towards union in a common university. They suggest that the governing bodies of institutions, such as the two colleges, should if possible be persuaded to hand over their trust to the Senate of the new University; rather a startling request, yet one which a recent vote of the Council of University College would show to be not absolutely absurd. One cannot help feeling, however, that King's College would have still greater difficulty in joining in such a scheme, as it was recently founded and endowed as a Church of England institution; and, although its trust funds might conceivably be reserved for the benefit of adherents (real or nominal) of the church, such an arrangement would cause great and

lasting discontent, and the influence of the college from the sectarian point of view would be lost. The authorities might, however, regard the establishment of a theological faculty in the University as a counterbalancing gain, for a faculty conducted by earnest men of wide sympathies would have greater opportunities for good than King's College alone could obtain.

Assuming that the two colleges consented to this absorption, and that the Government School of Science at South Kensington (many of the professors are strongly in favour of the scheme) came in with other institutions, it is supposed that the University would determine to use the buildings of each in various ways—e.g., those of King's College for arts and theology, those of South Kensington for pure science and those of University College for the technical application of science. The question at once arises, What is to become of the present teachers in these institutions? Many wild answers have been given, but the only one commending itself to sober judgment is that the institutions must be taken over by the University as "going concerns"—teachers and all—and that only as vacancies occur will the contemplated fusion become possible. Years will be necessary to the working out and development of the idea. All that has to be done now is to decide whether the idea or principle of centralisation is that from which the greatest University for London is likely to grow. Supposing the opinion of the majority to be in favour of this idea, the various institutions coming in to the University are put upon it, so to speak, as a child with a flexed hip is laid upon a Thomas's splint. There is to be no violent wrenching, with its accompanying pain and many dangers, but time is allowed in full confidence that the limb will settle down on to the splint with the minimum of local and general disturbance. Ultimately it is thought that there will be a university professor at the head of each branch of arts and science, but there may be any number of extraordinary professors, lecturers, readers and other teachers in the different branches.

But what is "the University" as the term is used in the professorial scheme? The proposals were that the University should consist of the Senate, faculties, convocation and undergraduates, but the constitution and powers of the Senate and the powers of the faculties were not defined. These are important matters about which, again, there are many opinions. The suggestion for the Senate which we have heard most often is that one-half should be nominated by the Crown and that the other half should consist of the University professors in about equal numbers from each of the faculties. This would be a very large body if anything like all the University professors had seats and many seem to feel that the supreme authority would be left in the hands of "irresponsible professors," "not representing anybody but themselves." But as a large outside admixture is contemplated, as an appeal to the Privy Council upon the action of the Senate is to be allowed to Convocation and as the powers of the faculties are yet unframed, it would probably be possible to provide against any sense of irresponsibility on the part of the University professors; if not, some other constitution of the Senate might be arranged. Every professor would be *ex officio* an examiner in his subject; other examiners not professors would be appointed to take part in all degree examinations. These latter may be members of the University or not. The right association of teaching and examining is thus assured. Lastly, it is hoped that the University will be the remodelled University of London; those who are striving to do away with injurious competition between colleges are anxious not to introduce it between universities. Moreover, it is stated that the Senate of the London University has recently, with only one dissentient voice, resolved that it would receive with favour a recommendation from the Royal Commission that a professoriate should be added to the London University with a substantial voice upon the Senate. Thus, the London University might become a teaching university for London with (as is suggested) its pass examinations open to the undergraduates only, but with its honours examinations open to the world.

How would medicine be affected? What position would it occupy in, and what advantages would it gain from, a professorial university? The supporters of the scheme say that in any university in London the medical faculty must be great, but that under the professorial scheme it will be associated with far greater brethren—if I may so speak of the other faculties—than is at all likely under the Gresham scheme. Its graduates and undergraduates would have

access to the University laboratories. The medical teachers of London are offered one-fourth of the professorial half of the Senate, supposing that there are four faculties at the start. All the teachers in the medical schools of London would have seats in the faculty, the functions of which would probably be electoral. The teachers would thus practically regulate matters medical; but the arrangements for the examination of medical undergraduates in arts and science would be made by the independent boards of studies in arts and science acting conjointly with that in medicine, a guarantee being thus afforded to the provincial schools that the new University will not neglect these matters in its medical degrees. On this understanding the opponents of the Gresham scheme have signed the proposals for a professorial university. The idea of "absorbing" the medical schools has never been entertained. It is suggested that the teaching of pure science (chemistry, physics and biology) might with advantage be placed in the hands of the University; but this does not imply that the University contemplates endeavouring to teach 500 or 600 first-year men in a single class. There is, however, no compulsion; each school can if it pleases continue to teach science and the University degrees will be open to its students. It is generally acknowledged that the amalgamation of some of the schools would render their teaching of certain subjects better than it now is. If the idea of the professorial university should be adopted the medical schools, like the colleges, will feel its influence, and those who believe in the idea are confident that amalgamation, so far as it is desirable for thorough teaching, will result. Other doubtful matters may be left to solve themselves.

As I understand things, we have now to make a choice between a university in which the central idea is the perpetuation of the interests of rival institutions and one in which institutions as such will have no weight and all forces will be united for the common good. Medicine, with its complete organisation in London and the examinations of the Conjoint Board conducted practically by London teachers, wants mainly the power to grant an M.D., and that it will get under either scheme. Shall its weight be thrown into the balance with the Gresham Charter, thus to secure the first place in a university of which real success is doubtful; or, looking to the general interests of education, shall it endeavour to obtain the establishment of a university in which its representation will be smaller—though still, upon the system adopted, proportionate—in which that great source of weakness—compromise—is set aside and the probability of free and healthy growth is correspondingly increased?

I am, Sirs, yours obediently,

July 20th, 1892.

STANLEY BOYD.

To the Editors of THE LANCET.

SIRS,—May I ask so much of your space as will suffice to remove from the minds of your readers any erroneous impression which might be conveyed by the article in your last issue, entitled "A Teaching University for London"? You refer therein to the scheme put forward by the Association for Promoting a Professorial University for London, which you there summarise under six headings. Those headings are taken from a document put forward in the first instance by the promoters of the Association. The Association itself has never accepted or sanctioned the document to which you refer. It appointed an executive committee to draft a scheme, which has received the approval of the Association, and which is the sole authoritative document of the Association. That document has been published in *The Times*, the *Academy*, *Nature* and other newspapers, and I enclose a copy of it for your perusal. It especially excludes the medical schools from the principle of absorption and leaves the constitution of the medical faculty largely in the hands of the medical teachers themselves, subject to some sufficient guarantee that a medical degree shall mark a general academic culture and not be the mere equivalent of a licence to practise. The executive committee of the Association are not only willing but desirous of working for a university which shall not be opposed by the medical schools either of London or of the provinces, but they cannot look with favour on a scheme like that of the Gresham Charter, which failed, in their opinion, to meet the requisites of a great modern university. As a matter of practical politics, I venture to think that it is as idle now (especially having regard to the probable change in the Government), as it was when I wrote to you in the spring, to work for the Gresham

Charter. The Association for Promoting a Professorial University is now a very strong body, and if the representatives of the medical schools can come to anything like an agreement with its executive committee, there will be a far better chance than has hitherto been possible for a really great metropolitan university.

I am, Sirs, yours truly,  
Crowborough, July 16th, 1892.

KARL PEARSON.

To the Editors of THE LANCET.

SIRS,—According to accounts the Royal Commission on a Teaching University for London is proceeding rapidly. Will you allow me through your columns to direct attention to one fatal blot in the last scheme which, it is to be hoped, will not reappear in the next?—viz., that the much-wanted medical degree for London students which is to counteract the centrifugal force of Scotch and provincial universities is to have no validity as a *qualification*, or as admitting to the Medical Register. Is it conceivable, Sirs, that if such an indignity be put on the new degree it can be tolerated? That while any other degree—from that of St. Andrews to that of Oxford—admits to the Register, this metropolitan University degree shall not do so? Unless the metropolitan community is sunk to such an apathy as to disentitle it to the university facilities of every capital in Europe and of every third-rate town in Germany or Scotland, such a stigma will not be borne, no matter what the vested interests are by which it is sought to be furtively imposed on a Parliament too much absorbed in party politics to care for academic ones. I am glad to be assured that this vital point is not being overlooked by all the Commissioners.

I am, Sirs, yours obediently,  
Highbury-place, July 20th, 1892.

JAMES GREY GLOVER.

## "APPARENT DEATH IN CHOLERA."

To the Editors of THE LANCET.

SIRS.—I notice, under the above heading, in *THE LANCET* of July 16th, page 154, the following statement in connexion with Dr. Pacini's pamphlet, "La Morte Apparente della Cholera," published thirty years ago:—"Among his prescriptions, that of the intravenous injection of bay-salt, as suggested and practised in 1832 by Dr. James Macintosh of Edinburgh, held a prominent place, and by this means, particularly in the cholera visitations of 1877 and 1884, the restoration to life of many duly certified as dead was just in the nick of time effected." The Dr. James Macintosh alluded to is doubtless Dr. John Mackintosh, for many years extra-academical lecturer in the Argyle-square Medical School. On consulting his work on the Practice of Physic it will be seen that he gives the credit of originating this heroic treatment of a disease that "begins with death" (as he was accustomed in his lectures to term "cholera") to Drs. Latta and Lewins of Leith, in which seaport the epidemic of 1832 was particularly malignant. The latter-named physician was my father, and I have often heard him speak of the improvement effected by the warm salt-water injection as only temporary and in no single case resulting in recovery, as apparently claimed for Dr. Pacini practically in the above extract from *THE LANCET*.

I am, Sirs, yours truly,  
Army and Navy Club, July 18th, 1892.

R. LEWINS, M.D.,  
Surg.-Lieut.-Colonel (R.).

## ANÆSTHETICS AT THE INTERNATIONAL MEDICAL CONGRESS.

To the Editors of THE LANCET.

SIRS,—On my return from the International Medical Congress held in Berlin in 1890 I ventured to express the opinion in your columns that at future Congresses it would be desirable to have a separate section for the discussion of anæsthetics and allied subjects. In your issue of July 9th you draw attention to the fact that we are now within measurable distance of the Congress to be held in Rome in September, 1893. Might I therefore be permitted again to express the hope that it will be found possible to make the alteration suggested? The increasing amount of attention which is being given to the subject is well known, and if any proof of this fact were necessary, it would be furnished by the pages of the Report of the Berlin Congress, just completed. In that report upwards of forty-five pages are

devoted to anæsthetics, and there can be little doubt that much more material would have been forthcoming but for the uncertainty which prevailed as to the particular section in which each individual paper was to be read, for the papers, demonstrations and discussions on the subject were distributed over seven sittings of five different sections. I need hardly add perhaps that by establishing a separate section or subsection for anæsthetics some of the pressure upon the other sections would be relieved.

I am, Sirs, yours faithfully,

J. FREDK. W. SILK,  
Assistant Anæsthetist to Guy's Hospital, Anæsthetist  
to the Dental School, &c.  
Weymouth-street, W., July 19th, 1892.

### "A MANUAL OF CHEMISTRY, INORGANIC AND ORGANIC, FOR THE USE OF STUDENTS OF MEDICINE."

To the Editors of THE LANCET.

SIRS,—I should not ordinarily contemplate replying to the criticisms contained in your pages of a work emanating from my pen, but in the review of my "Manual of Chemistry" in your last issue there is at least one statement both misleading and inaccurate, which, with your permission, I will briefly explain. I do not propose to touch upon the debatable points, concerning which differences of opinion exist among chemists, and in connexion with which I believe I am in accord with the majority of chemists, notwithstanding the dogmatism of your reviewer. What I wish to refer to is a mere matter of fact, about which there can be no question of controversy whatever, and for the expression of which I request, in simple justice, as much publicity as you have given to the notice in question. Your reviewer in part bases his idea that the book requires more careful revision and the exercise of greater care with the proof sheets upon his supposed discovery of three typographical errors in a book of 525 pages. He states that "Nitric acid, for example, is represented on page 117 as  $\text{OHNO}_3$ ." I know not whether this statement is due to careless reading, failing eyesight, or deficiency of chemical knowledge on the part of your reviewer, but a reference to the page in question will convince the merest tyro in chemistry that 20 molecules of  $\text{HNO}_3$  are indicated and that your reviewer has attached the cipher of the 20 to the  $\text{HNO}_3$ .

I do not dwell upon the question as to whether a review of a book should be exclusively directed to the dragging in of polemical matters and to the exposure of small printer's errors; such must be left to the taste of the reviewer, but I do think that a statement that a book "cannot be safely recommended until it is freed from the flaws to which we have made reference" should be based upon something more substantial than an error of eyesight or of comprehension on the part of a reviewer.

I am, Sirs, yours very truly,

Weymouth-street, W., July 18th, 1892. ARTHUR P. LUFF.

\*.\* A reference to the review will show that our criticisms were not in the main based upon the single typographical error, which is practically the only point to which Dr. Luff replies. The mistake may be an obvious one, even perhaps to the "merest tyro." Twenty molecules of  $\text{HNO}_3$  may be indicated, but as a matter of fact they are not represented. The "cypher" in front of the formula alluded to is not the figure 0, but the letter O. Our "dogmatisms" are the "dogmatisms" of Victor Meyer, Ostwald and other eminent chemists.—ED. L.

### DISPOSAL OF REFUSE.

To the Editors of THE LANCET.

SIRS,—Will you kindly allow me a little space to call the attention of my professional brethren to a subject which, I venture to think, is of great importance at this season of the year, especially as it is not impossible that we may have cholera in our midst before long? I refer to the disposal of the refuse taken by the parish authorities from our dustbins. The following extract from the report of the case of *Allhusen v. Vigers*, before Mr. Justice Chitty, in the *Daily Chronicle* of July 18th will give one an idea of the danger which is allowed to go on unchecked in our midst:—

The plaintiff, who is the owner and occupier of Teyford Abbey, Ealing, brought his action against the defendant, a contractor, for the

removal of town refuse, in respect of an alleged nuisance caused by deposit of this refuse about 400 yards from the abbey. Prior to the trial of the action he applied for an interim injunction to restrain the nuisance, which he contended was of such a character as to interfere with the comfort and enjoyment of his house and grounds. The defendant conveys the refuse he contracts for by barges on the Grand Junction Canal to the site in question, where it is deposited to the extent of 300 yards in length, thirty-five in width, and twenty-five in depth. The small from this heap was said to be very bad, and in certain directions of the wind was conveyed as far as the plaintiff's premises.

Can someone not suggest or invent a method of disposing of such refuse, so that it shall not remain a pestiferous heap of decaying animal and vegetable matter? Mr. Justice Chitty kindly allowed defendants three weeks to find means to prevent the nuisance, at the same time suggesting that there was no method known at present.—I am, Sirs, yours faithfully,

GEO. HERSHELL, M.D. Lond.  
West-st., Finsbury-circus, E.C., July 18th, 1892.

### THE TRANSFORMATION OF SMALL-POX INTO COW-POX.

To the Editors of THE LANCET.

SIRS,—I have been much interested in reading Dr. Hime's account of his supposed transformation of small-pox into cow-pox and only wish his experiments could set at rest the question of identity of variola and vaccinia. He has done what has been already accomplished by others and it has been pretty clearly shown that such supposed transformation has not been effected. I am still sceptical of the reality of such change, but am nevertheless quite open to conviction if Dr. Hime will afford further proof of the identity in origin of small-pox and cow-pox by transforming the latter into the former. This should be easily done if there is only one virus acting in the production of both. And what about sheep-pox, which in its clinical features and morbid anatomy so closely resembles human variola? The question of identity will not be solved until cow-pox can be converted into small-pox, which has not yet been done, and I am doubtful whether it will ever be achieved.

I am, Sirs, yours truly,

London, July 20th, 1892:

GEORGE FLEMING.

### THE HUNTERIAN LECTURES.

To the Editors of THE LANCET.

SIRS,—I have just read with the utmost surprise certain remarks in Mr. Robinson's lecture on villous growths of the breast, in which he says that in my paper on this subject I have grouped together the cases of duct papilloma and villous cancer as growths of a perfectly innocent nature. By what subtle alchemy the candid lecturer has deduced this perverse conclusion from my paper passes my comprehension. In order to rescue this little known group of diseases from the obscurity that had hitherto involved them I laid it down as a fundamental axiom (p. 858) that under the term "villous cancer," as commonly employed, two perfectly distinct kinds of neoplasm were included—viz., the non-malignant villous papilloma and the malignant tubular cancer. I fully set forth and contrasted the salient pathological and clinical features of each of these groups; so that it seemed to me impossible for anyone to mistake them in the future. This fundamental distinction, dimly foreshadowed in the varied nomenclature of previous observers, had never before been definitely set forth. Mr. Robinson now adopts it as his own conclusion, together with the rest of my work, and coolly asserts that I never made the distinction. The result is that this part of his lecture is merely a parrot-like repetition of my paper—published several months previously—which he has had the audacity to appropriate and pervert, but not the grace to acknowledge.

I am, Sirs, yours faithfully,

Proston, July 14th, 1892.

W. ROGER WILLIAMS, F.R.C.S.

### CONTAGIOUS DISEASES IN GARRISON TOWNS.

To the Editors of THE LANCET.

SIRS,—Having taken a great interest in the above for some years I read with satisfaction that the matter is being taken up. It is now high time that something was

done and that we should form ourselves into a body and endeavour to introduce a measure which would minimise the amount of disease. An article appeared in a recent number of one of your contemporaries which represents the state of affairs existing in garrison towns, particularly that of women discharging themselves repeatedly from a workhouse lock wards and disseminating disease among newly arrived soldiers and sailors, returning as frequently to the wards in order to be temporarily built up in order to meet a new regiment. This is just the state of affairs which exist in my lock wards and is most disheartening, for, with a few exceptions, all the women discharge themselves before they are fit to be at large and are in and out like "dogs in a fair." I entirely agree with the article in every respect and am sure that what exists in one military town must be so in others. Many in the town where I reside who signed for the repeal of the Contagious Diseases Acts see their error.—I am, Sirs, yours truly,  
July 17th, 1892.

UBIQU.

## THE BRITISH INSTITUTE OF PUBLIC HEALTH.

To the Editors of THE LANCET.

SIRS,—I am desired by the Council of the above Institute to inform you that they have made arrangements for holding their annual conference in Dublin on Wednesday, Thursday and Friday, Aug. 17th, 18th and 19th, 1892, under the presidency of Sir Charles A. Cameron, medical officer of health to the City of Dublin. I am further desired to say that the President and Council will feel obliged if you will allow me through the medium of your columns to cordially invite the medical officers of health of the country and other gentlemen interested in public health to attend.

I am, Sirs, yours faithfully,

C. A. JAMES, L.R.C.P., D.P.H., Hon. Secretary.

July 18th, 1892.

## THE FRENCH WORKMEN'S SANITARY CONGRESS.

(FROM OUR SPECIAL CORRESPONDENT.)

At the fourth sitting of the Congress the discussion on the Hygiene of Infancy was reopened by the labour delegate of the Municipality of Châtelleraut. He thought that the advice given by the learned professors who had delivered preparatory lectures was not always practical. It was supposed that cow's milk might convey tuberculosis and it had been shown how such milk could be sterilised; but working-class women had not the time to take such precautions and they were too untidy and too careless to carry them out effectively. Then it was said that tuberculosis in a cow could not be recognised till it had reached an advanced stage. This difficulty could be met by submitting all cows to an inoculation with Koch's tuberculin, and all cows displaying suspicious symptoms could be slaughtered. Thus the disease could be stamped out, to the great advantage of the bovine race and of humanity. This was more practical than asking workwomen to sterilise the milk.

A delegate from the eleventh arrondissement of Paris complained that poverty prevented workwomen from taking the necessary care of themselves and their children. When women went out as wet nurses, instead of suckling their own children, they were well fed and had good milk. If they remained at home the want of proper care and food impoverished their milk. Perhaps the milk was good for the first and the second child. The younger children of a workman's family were bred under the most unfavourable conditions and bore the stigma of the poverty into which they were born. Well might the population remain stationary. Yet if there is a right in this world it is certainly the right of the child to its mother's milk. The child did not ask to live; the mother belongs to the child and not the child to the mother. If the nation, if society, wished to live, society must mind its children. It was labour that made the wealth of society, it was society that profited by this wealth, and it was the duty and the interest of society to provide every creature born with the means of becoming a healthy and useful worker.

Mademoiselle Bonneval, of the School Teachers' Union, reported that the women employed in the State tobacco

factories had sent up petitions for the creation of a larger number of crèches with a demand for better medical surveillance. The Teachers' Union, specially represented by the speaker, thought that all congresses should have two objects—the proclamation of an ideal and the achievement of something immediately practical. They did not mind being called dreamers if by the side of their dreams they could show practical improvement. The ideal would be to abolish all crèches, all nursing and maternity establishments, and to give all mothers the means of enjoying abundance in healthy homes. The speaker freely recognised the great evil of the aggregation of children. The discipline inseparable from such establishments deprived children of that freedom so essential to their healthy development. It was wrong to make young children sit in classes. Parents were much to blame for trying to bring up their children as infant prodigies. Song and frolic should be the spontaneous and joyous outcome of freedom and health. Freedom is what the child wants, morally and physically. Freedom to run, to jump, to play with the earth, which seems the favourite of all amusements, as if the child felt instinctively that the earth was its first mother and was destined to provide its food for life. "Let those little children make their mud pies," pathetically pleaded Mdlle. Bonneval.

The delegate of the Port de Mandres denounced clerical orphanages. In some of these the children had very little food and were terribly overworked. Yet they did not learn a trade, for the labour was so subdivided that when they left these establishments they were unfit to earn their living outside. He more particularly protested against the system of punishment consisting of solitary confinement. This tended to develop secret vices, more particularly among the girls, who became hysterical, anemic and sometimes idiotic. In the name of virtue, humanity, and hygiene he demanded the suppression of the convent workshops.

The Congress then proceeded to discuss the third question, the Hygiene of the Workmen's Home. M. André Gély, who is a member of the official Commission on Unwholesome Dwellings, reported to the Congress. He lamented the tendency of the working classes to struggle only for political ends; they were constantly carried away by the "tall talkers," and men of science failed to move the masses. They could not get up an outcry against bad drainage and inefficient ventilation. Yet the housing of the population of Paris was at present in so deplorable a condition that there were proportionately three deaths in the poor quarters to every single death in the rich quarters. The poor slept three or four in the space where only one or two ought to live. Statistics also proved that in the districts of Paris where the old cesspools still existed the death-rate was higher. The existing laws were altogether inefficient. The appointment of a commission on unwholesome dwellings was optional. Only about a dozen of the more intelligent and important municipalities of France had appointed such commissions, and there were 36,000 municipalities in France. Some slums, it is true, had been abolished, but many remained that were quite as bad. It was absolutely necessary that a Ministry of Public Health should be created.

On the following day the Congress was presided over by M. Mercier, house painter and decorator, delegate of the municipality of Rochefort-sur-Mer. In opening the proceedings he demanded that the law of 1852, by which the outside of all houses had to be cleaned once in every ten years, should be made to apply to the inside of houses. He protested against the proposal to make workmen live in the suburbs of great towns; this would be most injurious, since it was by living in the centre, surrounded by the best shops, that the artisan acquired and preserved his ideas and his good taste. He protested against the model artisans' dwellings built on the Buttes de Chaumont, as tending to separate class from class. Philanthropists, with the best of intentions, were doing great harm by treating artisans' dwellings as something quite apart from the general questions of hygiene. If they wished to avoid class wars they had better mix and not separate the classes.

M. A. Lavy, member of the Chamber of Deputies, profited by an interval to express the gratitude of the Congress to the foreign press, but more especially to THE LANCET, for the publicity given to the work of the Congress. It was most essential that men of science, sanitary reformers, and legislators should know what the workmen themselves thought of the many efforts made to improve the sanitary condition of the great mass of the people. The publicity given, especially by THE LANCET, would tend to this end

and help to bring about harmony between the organised workers and the sanitary reformers of different countries.

Continuing the discussion, M. Forget, of the Newspaper Carriers' Society, complained that workmen could not effect improvements in the condition of their dwellings, for as soon as they appealed to the sanitary authorities they received notice to quit from their landlords.

M. Saint-Domingue, delegate of a labour group of Positivists, spoke of the fatal moral influence of unwholesome dwellings. When families live in one room children lost all sense of respect for their parents. Rents need not be reduced, but the accommodation should be much improved. The father was driven to the café to escape the discomfort and overcrowding of his home. The girls also, eager to make their escape from home, went early to the factory; they therefore did not learn how to keep house. The good housewife was fast disappearing, and this again added to the discomfort of the worker's home; and all of which led to out-door life, to drink and vice.

M. André Gôly continued his report and stated that the committee of the Congress appointed to study this question had received nine reports from various workmen's societies. There were points in common in these reports; these would be embodied in the resolutions to be submitted at the last sitting of the Congress. The Port de Flandres group had calculated that there was human flesh to the extent of about 3,000,000 kilogrammes buried in and about Paris. This must be an active cause of insalubrity, and the report concluded that cremation should be obligatory for all large towns. The Versailles group had a technical report on the disposal of slop-water, concluding in favour of a law rendering the use of sinks with trapped pipes obligatory. Though all the reports sent in demanded great improvements in house accommodation, there was not a single labour society or a single individual workman who asked for or approved of the building of artisans' dwellings. One report urged that the municipality should create washhouses and forbid home-washing. The floors were infected by the slops from dirty linen, and small apartments in crowded towns were not the proper places for washing dirty clothes. There should be more facility for taking baths. A great deal of the difficulty in finding house accommodation was due to the spirit of speculation. This would be checked if untenanted apartments were taxed in the same manner as tenanted houses.

Dr. Paul Brousse was glad to see that workmen had recognised the economic necessity of abandoning the small cottage home. With regard to dwelling in a large building, he pointed out the greater luxury which association and collective effort brought. To very large piles of buildings should be attached club-rooms, libraries, baths, gymnasias and all the facilities that science and industry had devised. M. Caumeau, M. Dalle, and other speakers demanded the better inspection not merely of dwellings, but of offices and workshops. They urged that private sanitary committees should be appointed to stimulate the action of public bodies, and that the municipal councils should have the legal power of destroying unwholesome and condemned dwellings.

The Congress now proceeded to discuss the fourth and last question, the Hygiene of the Factory, Workshop, &c. M. Dalle was reporter on this question. A report had been received from the Fargan district, dealing with the kilns in which bricks are baked. Here men, almost naked and covered with only a wet cloth, worked in a temperature of 70° centigrade. Sixty per cent. died prematurely from chest complaints and from the asphyxia caused by breathing the carbonic acid gas which was produced by the clays of Vaugirard. These men earned only fourpence per hour. The report concluded in favour of limiting the hours of labour and of constructing kilns of a less dangerous description.

The saddle-makers reported on the bad effect on health and eyesight of the numerous underground workshops existing in their trade. Women were also made to work such heavy sewing-machines that their health generally failed them when they reached the age of thirty. The Academy of Cooks sent in a report dealing with the foul air in underground kitchens, which were generally situated close to untrapped drains. They had petitioned the authorities, but all to no purpose. Cooks had sometimes to remain fifteen hours in kitchens where the temperature varied from 55° C. to 68° C. The metal polishers described how they were poisoned by the effluvia of cyanide of potassium. The Versailles bakers demanded that the law should prohibit the existence of closets inside bakehouses and should see that bakehouses were properly ventilated. The river bargemen and the crews of tug boats reported on the terrible

condition of the stokeholes in these little river steamers; the temperature rarely fell below 55° C. The State match-makers reported upon the bad ventilation of their factories, and the tobacco manufacturers made a similar complaint. The printers and compositors denounced the unwholesomeness of their workshops. The house decorators wanted a law compelling the use of zinc instead of lead for making paint. They related that though there were police decrees to enforce proper precautions for the security of scaffolds outside houses in the streets these decrees did not apply to scaffolds erected in back yards and within houses. The tanners and leather-dressers wanted the abolition of the use of picrate and the employment of lime instead. The gas-workers demanded the inspection of the places where they worked and that baths should be attached to all gasworks. All the trades demanded that proper waterclosets should be provided instead of the insanitary untrapped and unflushed closets that now exist. Though there was so much to be said on this fourth question the discussion had to be cut short as the time had now arrived to put the resolutions before the closing of the Congress. These resolutions were all carried unanimously, but they would not be considered as resolutions in England: they were more like essays on the various subjects, and would, taken altogether, form a good stout pamphlet. On the first question (Food Supply) the resolutions were comparatively brief; they set forth the conflict of interest between the tradesman and the consumer, and the imperative necessity of providing the population with wholesome food. This end it was considered would be best secured by establishing municipal bakeries, butchers' shops &c., and by the amendment of the law on adulteration so that food in the course of preparation might be seized, and the premises not only of the retailer, but of all middlemen and manufacturers concerned might be subjected to inspection and the articles seized analysed.

On the second question, the Hygiene of Infancy, the resolution had a preamble to the effect that infants had a right to thorough "integral" protection, which at present was not given to either woman or child, yet horticulturists gave such protection to plants under their care. Was not the infant a young plant in the hands of society? Women should be prevented from working beyond their strength during the period of gestation. The Roussel Law of Dec. 20th, 1874, was the first attempt to protect infants; and though this had done much good, still there were more deaths in the course of a year from the use of the long-tubed bottle than there had been soldiers killed in the biggest battle. Therefore the resolution concluded that laws should prevent nightwork and overwork for women; and their employment during the more advanced periods of gestation should be prohibited; no mothers capable of suckling their children ought to be allowed to hire wet nurses. The sale of long-tube bottles should be rendered illegal. Maternities ought to be established, where mothers need not give their names and where they could remain and nurse their children till the latter were two months old. The convent asylums ought to be placed under the common law. Women who hired wet nurses should be made to pay a tax of £8, and every measure possible should be taken to compel mothers to suckle their own children.

On the third question, the Hygiene of the Worker's Home, the resolution condemned barrack-like artisans' dwellings, demanded strict legal enactments for the enforcement of proper drainage; trapped and flushed closets; municipal baths and washhouses; the creation of a Ministry of Public Health; the obligatory instead of optional appointment of sanitary committees in all the communes of France; the disregard of sanitary laws to be punished by imprisonment as well as fines; the right of sanitary inspection at all hours, inspectors to take the initiative and not to wait till they receive complaints, such inspection to include factories and workshops; municipalities to be prevented from alienating communal land, but to build upon such land model dwellings; untenanted property to be taxed as heavily as tenanted property; new sanitary laws for the building of new houses and the reform of old houses, giving strong compulsory powers to the municipalities.

The resolution on the fourth question was of great length and took about half an hour to read. It is impossible even to summarise such a resolution. It went into the detail of the grievances of a great variety of trades. The resolution suggested that four sanitary services might be organised to deal with the four phases of sanitation discussed at the Congress; that a Ministry of Public Health should be

erected to study and prepare sanitary laws and establish technical schools of practical hygiene; that committees of inspection &c. should have as members some representatives of the class that suffers most and no representatives of the class that benefits by the infliction of such suffering; that the existing law for the election of working miners as inspectors of mines should be extended to all other trades and manufactories; places where work is done should be roofed, staircases washed once a month, concrete floors provided where organic matter is used, these floors to be frequently washed with disinfectants; walls painted with zinc paint; one closet for every ten workers; separate closets for females; all closets to be well trapped and flushed; each worker should have twenty-five cubic metres of space allowed him and there should not be more than fifty workers in one workshop; all workshops should receive direct light from the sun and underground workshops should be abolished; powerful mechanical ventilation should be provided where there is metallic dust and other dangerous dust or poisonous gases; there should be dining-rooms separated from the workshops &c.; a good water-supply on the premises; work in tunnels and places subject to malaria should be stopped during the two most dangerous months of the year; efficient means of escape in case of fire; ambulances and medical attendance in case of accident should be supplied, &c. To enforce all these and many other demands fines and penalties of all sorts were proposed. It was impossible for the Congress to discuss all these details, but with full confidence in the reporters these four lengthy resolutions were each in turn, as already mentioned, adopted unanimously. Then the Congress reaffirmed the resolutions carried at the great international labour congresses of Paris, London and Brussels in favour of international legislation on the hours of labour, unwholesome industries &c.

Finally, M. André Góly rose to close the Congress. The Congress, he said, had exhausted its programme. All workers would be grateful for what had been accomplished. They had made popular questions which in France had previously been known only to men of science. The reports presented to the four commissions on the four questions proved the interest which had been awakened among the working classes. These reports were very carefully drawn up and were full of facts and figures. They showed how the workers had realised the necessity of health and consequently of sanitary legislation. In the name of the Organising Committee he returned thanks and complimented the Congress on the admirable order and unanimity which had been maintained throughout.

The Congress then broke up amid cheers. During the week the delegates visited the sewers, the catacombs, the municipal laboratory, the disinfecting station, and other places of interest.

## LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

### *The Visit of H.R.H. the Duke of Connaught.*

ALTHOUGH the main object of the visit of the Duke of Connaught and Strathearn to this city was the inauguration of the water-supply from Lake Vyrnwy, his Royal Highness made a pleasing addition to the programme by volunteering to visit the Royal Southern Hospital and Sefton Park. Both of these were opened some years ago by the Duke, and his recollection of the double event was so pleasing that he wished to see again the hospital which has, since it was opened by him, been the means of relieving so many of those injured in the daily battle of life incidental to such a city as this and treated in a hospital situated near the southern docks and other localities whence accidents and urgent cases come. The park, moreover, has afforded healthful recreation to all the residents of that and other portions of the city, to rich and poor alike. The inauguration of the water-supply was successfully accomplished and the Duke received a most hearty welcome.

### *Election of Surgeon to the Northern Hospital.*

The trustees of the Northern Hospital were the first to change the mode of election of honorary medical officers from the general body of trustees to an elective committee on the lines suggested by a subcommittee of the medical institution and confirmed by the members generally. This elective committee met for the first time on the 15th inst. to elect a surgeon in the place of Mr. George Gibson Hamilton, recently

elected to the office of assistant surgeon to the Royal Infirmary; out of a total of one hundred and twenty members sixty-six attended. Mr. Arthur Henry Wilson, surgeon to the Stanley Hospital, was elected. The experience of the two recent elections under this new system has been very satisfactory and its superiority over the former mode has been generally admitted.

### *Copper and Green Peas.*

Last week a retail dealer was charged with an offence against the Food and Drugs Act in having sold peas adulterated with sulphate of copper in such a quantity as to be injurious to the health of the consumer. A tin of peas, weighing 1 lb., was purchased for 10½d. by an official of the Health Department. Mr. Williams, the assistant county analyst, stated that experiments had proved to him that the copper was capable of being absorbed into the system, and that in the case before the court there were two grains and a half of copper in the tin. Dr. Campbell Brown, the city analyst, stated that the sulphate of copper did not preserve the natural pigment of fresh green peas. He would hardly say the coloured peas were injurious to health in the ordinary sense of the phrase, but the effect of the sulphate of copper in the proportion shown in this case with an ordinary amount of peas was astringent and the effect would by no means pass off after the food had left the stomach. Stale peas boiled with sulphate took the colour of fresh peas. The peas sold by the defendant would injure the digestive powers of people with weak stomachs. Dr. Hope, assistant medical officer of health for Liverpool, said that no more than a grain and a half of copper was necessary to every pound of peas. Mr. Stewart, the stipendiary magistrate, was satisfied that the quantity of copper used was injurious to health. He thought the wholesale manufacturers were more responsible than the tradesmen, who trusted to them. The latter should protect themselves by getting a written guarantee from the manufacturers that there were no injurious ingredients in the goods they supplied. Under the circumstances he would not impose a larger fine than 30s., with all the costs. A second dealer was similarly fined for a like offence.

Liverpool, July 19th.

## NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

### *The Heath Chair of Comparative Pathology at Newcastle.*

MR. F. PAGE, surgeon to the Royal Infirmary here, in a reprint of his lecture last session on Parasites, makes a timely reference to the generosity of a respected citizen of Newcastle, Mr. Clement Stephenson, F.R.C.V.S., whereby the College of Medicine has been enabled to establish within its precincts a laboratory thoroughly equipped with the most modern appliances for the study of the many interesting problems constantly arising in this department of study. Mr. Page goes on to say that Professor G. Y. Heath, the late distinguished and able president of the College of Medicine, deemed the study of disease as it affects the whole animal kingdom of such paramount importance to the community that he bequeathed the sum of £5000 for the chair of Comparative Pathology and its endowment. This professorship will be called after the name of its far-seeing and generous founder. In connexion with Dr. Heath's bequest I hear that he has also left his museum of pathological preparations and the bulk of his valuable medical library to the Newcastle College of Medicine.

### *The Newall Telescope at Cambridge.*

Although we were sorry to lose the late Mr. Newall's magnificent telescope from Gateshead, where the climatic conditions were not favourable, we are, on the other hand, pleased to know that it has got a proper astronomical home, so to speak, at Cambridge. We hear that it has been set up there on a conical frustum of special concrete nine feet six inches deep, on a circular base ten feet in diameter. The removal from Gateshead would cost, together with the necessary clockwork and machinery, about £1500, towards which the Sheepshanks Fund has contributed £1000, so that the University chest has been only asked for about £168.

### *Centenarian Voters.*

Of centenarian voters I (imitating the caution shown in an annotation in THE LANCET of last week) "can only speak at present in the singular number," but I can vouch for the fact

that Mr. Thomas Ironsides, farmer, of Kibblesworth, near Gateshead, voted last week in his district. Mr. Ironsides is in his 102nd year, and until I hear to the contrary from your numerous and well-informed correspondents I claim him to be the oldest voter in the country, and challenge them to produce an older one.

#### *Sunderland.*

Sunderland is about to lose its able medical officer, who has effected so many sanitary reforms for the borough in his long tenure, Mr. Alfred E. Harris having received the post of health officer to the metropolitan district of Islington. While we are sorry to lose Mr. Harris we are glad to hear of his promotion. Mr. Harris has been long esteemed in Sunderland as a professional brother, as a sanitarian and as a citizen. It is reported that the Sunderland Corporation contemplate pulling down two areas of insanitary property; the cost in the first case is £5750 and in the second £9600. Some 300 tenants will be "disturbed," it is said, which is a mild way of stating that some poor people will be rendered homeless; unless some equivalent provision is made for them there is certain to be dangerous overcrowding.—An inquest was held the other day on the body of a woman who died at her residence at Sunderland from the effects of a paraffin lamp explosion.—At the annual meeting of the North of England Branch of the British Medical Association, held at Sunderland on last Tuesday, Dr. James Murphy, President, in the chair, it was resolved to form a representative committee to give a cordial invitation to the British Medical Association to hold their next meeting (1893) in Newcastle-on-Tyne; and, in case of its acceptance, complete arrangements were made for the purpose.

#### *Durham City.*

At the late assizes held at Durham the Judge drew attention to the series of foul odours experienced in the court, and had more than once to apply his handkerchief to his nose to mitigate the smells. He asked who was responsible for the state of the court and was told it was the High Sheriff. The Judge replied that as that official and the Under Sheriff were away courting votes he could not send them to prison; but if the atmosphere of the court was not made purer the assizes would have to be removed another time to Newcastle. His Lordship instanced the case of Leeds, where the assizes were on the point of removal to York until the Corporation of Leeds awakened to the necessity of doing something. It seems that by a liberal supply of disinfectants the business of the court did proceed. Well, Durham is a slow place, but if it does not mend its unsanitary ways it will get a harder name.

Newcastle-on-Tyne, July 21st.

## SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

#### *Close of the Summer Session in Edinburgh.*

Most of the classes in the Edinburgh Extra-Mural School of Medicine closed last Friday; some of the practical classes are, however, still going on and the classes in the University do not finish until Friday of this week.

#### *Medical Examinations in Edinburgh.*

The second professional examination in the University commenced on Monday and the first professional will begin on Monday of next week, after the close of the session. The various examinations for the Scottish triple qualification which have been going on for the past fortnight have almost finished; there has been a large number of candidates and a considerable proportion of rejections.

#### *Scottish Universities Commission.*

The Commission is still taking evidence on the question of materia medica. Last week Professors Hamilton of Aberdeen and Greenfield of Edinburgh gave evidence on the relative positions of materia medica and pathology in the curriculum.

#### *Royal Edinburgh Hospital for Sick Children.*

The directors at their meeting last week appointed Drs. W. Ford Robertson and W. B. Drummond to be resident physicians to this hospital for six months from Nov. 1st. These gentlemen are at present resident physicians in the Royal Infirmary.

#### *The Health of Edinburgh.*

The mortality last week was 68, making the death-rate 13 per 1000. Diseases of the chest caused 9 deaths and

zymotic diseases 6. The intimations for the week were—typhoid fever 6, diphtheria 5, scarlet fever 38, and measles 27.

#### *Health of Leith.*

The death-rate of this burgh last week was 20 per 1000. Of the total of 27 deaths 15 were of children under five years of age and 10 under one year. There were 15 new cases of scarlet fever reported.

#### *Health of Aberdeen.*

For the month of June Dr. Matthew Hay reports that scarlet fever is again on the increase, 70 cases with no deaths having been reported. Since February 1st 230 cases have occurred, with only 2 deaths, or a mortality of less than 1 per cent. Whooping-cough, although less prevalent, is far from having been eradicated, and it compares very unfavourably with scarlet fever in respect of mortality. An outbreak of measles has occurred in the fisher quarter, Torry, and several cases of concealment of the disease have come to the knowledge of the Public Health Department. The outbreak is, however, almost at an end, and the other quarters of the town have escaped. Diphtheria is accountable for 3 deaths out of 5 cases reported. Four cases of typhoid fever and 3 fatal cases of puerperal fever have been notified. Although no cases of typhus fever were notified in May and it was thought that it had again disappeared from the town, a small group of cases has been discovered during the present month in a new tenement in an old quarter of the town. Not only the infected members, but the whole family have been removed to the city hospital for observation and treatment.

#### *Aberdeen University: Close of the Summer Session at Marischal College.*

During the past fortnight the examinations for medical and surgical degrees have been held, the summer session having ended on July 8th. The number of candidates is about the average. The candidates for the D.P.H. are also undergoing examination, and last week there were about a dozen candidates for the certificate of the Medico-Psychological Society. The "capping" will probably take place on Tuesday, July 26th.

#### *Presentation to Dr. Maohenzie Booth.*

The officers and men of the 7th Company Volunteer Medical Staff Corps met on July 18th at headquarters and presented Surgeon-Captain J. M. Booth with a handsome silver épergne as a marriage gift. Surgeon-Captain MacGregor made the presentation in highly felicitous terms and Surgeon-Captain Booth made an appropriate response.

#### *Proposed Hospital for Peterhead.*

At a recent meeting of the Peterhead Town Council a discussion took place on the advisability of erecting a hospital for the town or for the town and district. Except for one dissident, who thought they should not adopt the Notification Act until compelled so to do by Parliament and who thought a town with a death-rate of only 14.5 per 1000 was in no need of a hospital, the members of the board were enthusiastic in their approval of the scheme.

July 16th.

## IRELAND.

(FROM OUR OWN CORRESPONDENT.)

#### *National Hospital for Consumption.*

UP to the middle of July the total collected or promised for the proposed Hospital for Consumption amounted to the handsome sum of £9420 14s. 1d. No site has yet been selected, but there is little doubt that the promoters will ultimately select some place adjacent to Dublin.

#### *Cholera Precautions.*

In consequence of the prevalence of this dread disease in certain parts of France and countries bordering on the Black Sea the Local Government Board have issued orders prohibiting the importation into Ireland of rags from these countries.

#### *Longevity in Ireland.*

For the March quarter the number of centenarians in the mortality returns was something unusual. Twenty-eight deaths were registered of persons whose ages amounted to 100 years and upwards. Of these, seven were 100 years of age, two 101, four 102, two 103, six 104, two 105, two 106, one 107 and one 109 years. The latter died in the

Macroon Workhouse, where she had been an inmate since its establishment.

*Board of Superintendence of Dublin Hospitals:  
Annual Report.*

The thirty-fourth annual report for the year ended March 31st last, on the condition and management of the nine Dublin hospitals which receive Parliamentary grants, has been issued. As regards the Lock Hospital the Board again refer to the faulty condition of the laundry, which is located in the basement immediately beneath an occupied ward. The only exercise ground available for the patients is a small yard with bare walls—a confined, shut-in place and totally unfit for its purpose. Being, however, situated in the centre of the city, no better recreation ground can be provided; but if the institution were removed to the suburbs various necessary improvements could be carried out. The Meath Hospital, as usual, is efficiently administered, and reference is made to a new department erected during the year, partly external to the main building, for receiving and dressing accident cases. This has been a great improvement, as before its erection extern accident cases had to be brought into the hospital, which at night time was calculated to disturb the patients in the wards. Additional wards have been opened in Cork-street Fever Hospital owing to the greater variety of infectious diseases now admitted since the Infectious Diseases Notification Act came into force. The mortality was 9.27 per cent. A suitably furnished children's ward has been added to the recent improvements in the House of Industry Hospitals, and plans have been obtained for converting the present chapel into a small-pox hospital which will be capable of accommodating twenty-four beds, the sanitary arrangements being isolated from the wards. The Rotunda Lying-in Hospital enjoys a well-deserved reputation and the renown of its clinical teaching continues to attract a large number of students. A ward on each storey is allotted to patients in actual labour, the floors being laid down with concrete, which prevents their being saturated with organic matter. Particular attention has been given to the dietary of the pupil nurses, and the board-room is used by them as a dining hall until the proposed new building is completed. The mortality of the labour patients was at the extremely low rate of 0.48 per cent. The drainage system of the Coombe Lying-in Hospital was very defective and a thorough overhauling has taken place, new pipes being laid down in place of the old sewers and the waterclosets replaced by modern patterns. Four deaths from septicaemia occurred, and the mortality of labour cases was 1.82 per cent., or eight deaths in 439 cases. The structural defects of St. Mark's Ophthalmic Hospital and the inadequate space for the inmates limit its usefulness, while the imperfect ventilation of some of the wards must prove injurious to the patients and often hazard the success of operations. The proposed amalgamation of St. Mark's with the National Eye and Ear Infirmary has made no progress and a considerable time must elapse before any definite steps are taken. The average annual cost per bed for maintenance in these nine hospitals varied from £15 11s. 6½d. in St. Mark's to £29 2s. 7½d. in Cork-street Fever Hospital; while a much larger discrepancy is observable in the average annual cost per bed for maintenance and for establishment charges—for example, in the Hospital for Incurables it amounted to £31 10s. 2d. and in Cork-street Fever Hospital to no less than £90 19s. 5½d. The Government grants amount to £15,722 15s. 9d., of which the House of Industry Hospitals obtain £7472 15s. 9d., the Westmoreland Lock Hospital £2600, Cork-street Fever Hospital £2500, smaller sums being allocated to the Meath, Steevens', Rotunda Hospitals, &c.

*The late Mr. Colles.*

The committee of the National Eye and Ear Infirmary at a recent meeting passed the following:—"That the committee have learned with deep regret of the death of Mr. William Colles, for many years consulting surgeon to this hospital, and desire to record their sincere sympathy in their bereavement with Mrs. Colles and her family."

*Appointment of Surgeon to Her Majesty in Ireland.*

I hear with considerable satisfaction that his Excellency the Lord-Lieutenant has recommended Mr. Philip Crampton Smyly, the well-known Dublin surgeon, for appointment as surgeon to the Queen in room of the late Mr. Colles. I specially mentioned his name some weeks ago as Mr. Colles' probable successor, and have only now to add that the

appointment is one which will be regarded as eminently satisfactory.

Sir George Porter, Bart., Regius Professor of Surgery in the University of Dublin, has been elected consulting surgeon to Sir P. Dun's Hospital, in the room of the late Mr. William Colles.

The returns of pauperism for the March quarter, compared with the corresponding quarter of last year, show a slight increase in the average number of workhouse inmates on Saturdays during the quarter, but a decrease of 2337, or 3.6 per cent., in the average number of persons on out-door relief.

*A New Sterilising Filter.*

MUCH misconception prevails amongst the public concerning the efficacy of filters, most people believing that, provided it be passed through any apparatus labelled a filter in the shops, the most foully contaminated water is rendered harmless for the purposes of consumption. Hygienists know, on the contrary, that natural filters or even the passage of water through a layer of sand does not enable water companies to guarantee the purity of the product distributed by them to their customers. The discovery of a new and effective method for the sterilisation of water supplied to towns by those well-known bacteriologists MM. Babès was announced by Professor Cornil on the 12th inst. to the Académie de Médecine. The principle underlying the method is the precipitation by means of appropriate substances of the micro-organisms whose presence in drinking water is so undesirable. The water is made to percolate vast reservoirs containing a thick layer of iron filings, through which there is passed at the same time a current of air. The percolated product is collected in large cemented tanks, from which it is decanted for use at the expiration of twenty-four hours. The efficiency of the apparatus is apparent from the fact that water which previously contained from 1200 to 1300 germs per cubic centimetre yielded, after decanting, only a proportion of 0.20. An additional advantage possessed by this filtered and practically sterilised water is the presence in it of CO<sub>2</sub> (from the decomposition of the FeCO<sub>3</sub>), which confers on it a slightly acid taste and renders it sparkling and refreshing without any chalybeate flavour, iron being conspicuous by its absence. A modification of this wholesale method is recommended for household purposes. A zinc or glass vessel, with a capacity of from ten to forty litres, and standing on a wooden pedestal, is pierced near its base with an orifice into which is introduced a rubber cork traversed by a glass tube provided with a tap. The reservoir having been filled with water, one and a half grammes of powdered alum are added for every ten litres and the contents are well shaken, either manually or by means of a rotatory mechanism, the vessel being finally covered with a well-fitting tin lid. After a lapse of eighteen or twenty-four hours the water may safely be used, it being, however, a good precaution to first allow about half a litre to run away. Besides the alum, alternative sterilising substances such as sulphate of iron or prepared chalk may be utilised. Practical sanitarians will readily appreciate the importance of the Babès method, controlled as it is by rigid bacteriological analysis which amply confirms its very great value.

*Self-mutilations by General Paralytics.*

Accusations, mostly false, brought against attendants, of ill-treatment of patients affected with that too common variety of mental alienation, general paralysis of the insane, are familiar to every practitioner. It is, therefore, a matter of importance to be fully aware of the injuries which such patients are wont to inflict upon themselves. M. Vallon observes (Société de Médecine Légale, 11th inst.) that certain general paralytics are in a constant state of agitation, their upper and lower extremities never being still. Others occupy their whole time in alternately buttoning and unbuttoning their clothes, dressing and undressing, while others, again, tear their clothing or the sheets. These latter patients may, especially when totally confined to their beds, inflict on themselves more or less extensive injuries without the attendants knowing anything about it. M. Vallon gives a few instances of such mutilations produced by constantly recurring movements of limited range. One sufferer had a long deep wound of the thigh caused by the nails of the right hand in its

incessant to-and-fro movements. In another the testes had been similarly laid bare, while yet another had lost part of the nose through the same mechanism. Constant grinding of the teeth is common in this class of patients, entailing the ultimate wearing down of those masticatory instruments. A habit of continually sucking either *à vide* or the sheets or pillows is also met with. One of M. Vallon's patients was suffocated by a poultice, which, originally applied to a wound, the defunct paralytic had sucked almost in its entirety. Another curious case is that of a man in whom enormous swelling, followed by gangrene of the lower lip, had resulted from this constant sucking. These few examples suffice to emphasise the necessity of closely watching general paralytics who, arrived at the terminal stage of their disease, may, during the long hours of the day and especially the night, succeed in damaging themselves very seriously.

#### *Suggestion as a Remedy for the Morphia Habit.*
